Wax and oil of turpentine might also be tried as additions: these being the common ingredients in such cements as we have accounts of are the firmest. Strong ale wort is by some directed to be used, instead of water, to make mortar of lime-stone be of a more than ordinary strength. It is possible, that the use of this tenacious liquor, in the powdered ingredients of this proposed plaster, might greatly add to their solidity and firmness.

**PLASTIC**, πλαστικός, denotes a thing endued with a formative power, or a faculty of forming or fashioning a mass of matter, after the likeness of a living being; such a virtue as some of the ancient Epicureans, and perhaps the Peripatetics too, imagined to reside in the earth, or, at least, to have anciently resided therein; by means whereof, and without any extraordinary intervention of a creator, it put forth plants, &c.

Some of them seem to be of opinion, that animals, and even man himself, was the effect of this plastic power.

**PLASTICE**, the plastic art, a branch of sculpture, being the art of forming figures of men, birds, beasts, fishes, &c. in plaster, clay, stucco, or the like.

**PLAT-VEINS**, in the manege, the veins wherein we bleed horses, one in the lower part of each shoulder, and the other in the flat part of the thighs.

**PLATS of a Ship**, flat ropes made of rope-yarn, and weaved one over the other; they serve to save the cable from galling in the hawse, or to wind about the flukes of the anchors, to save the pennant of the fore-sheet from galling against them.

**PLATBAND of a Door or Window**, is used for the lintel, where that is made square, or not much arched; these platbands are usually crossed with bars of iron when they have a great bearing, but it is much better to ease them by arches of discharge built over them.

**PLATBANDS of Flutings**, are the lists or filets between the flutings of columns.

**PLATE**, in commerce, signifies gold or silver wrought into vessels, for domestic uses.

**PLATE**, in heraldry, is a round flat piece of silver, without any impression; but, as it were, formed ready to receive it.

**PLATE**, is also a term used by our sportsmen, to express the reward given to the best horses at our races.

**PLATES**, in gunnery. The prise-plates are two plates of iron on the cheeks of a gun-carriage, from the cape-square to the center, through which the prise-bolts go, and on which the handspike rests when it poises up the breech of the piece.

Breast-plates are the two plates on the face of the carriage, one on each cheek. Train-plates are the two plates on the cheeks, at the train of the carriage. Dulidge-plates are the six plates on the wheel of a gun-carriage, where the fellows are joined together, and serve to strengthen the dulidges.

**PLATFORM**, in the military art, an elevation of earth, on which cannon is placed, to fire on the enemy; such are the mounts in the middle of curtains: on the rampart there is always a platform, where the cannon are mounted.

It is made by the heaping up of earth on the rampart, or by an arrangement of madriers, rising insensibly, for the cannon to roll on, either in a casemate, or on attack in the outworks.

**PLATFORM**, in architecture, is a row of beams, which support the timber-work of a roof, and lie on the top of the wall, where the entablature ought to be raised.

This term is likewise used for a kind of terrace, or broad, smooth, open walk, at the top of a building, from whence a fair prospect may be taken of the adjacent country. Hence an edifice is said to be covered with a platform, when it is flat at top, and has no ridge. Most of the oriental buildings are thus covered, as were all those of the ancients.

**PLATFORM**, or **ORLAP**, in a man of war, a place on the lower deck, abaft the main-mast, between it and the cockpit, and round about the main capstan, where provision is made for the wounded men in time of action.

**PLATONIC**, something that relates to Plato, his school-philosophy, opinions, or the like; thus, Platonic love, denotes a pure spiritual affection, for which Plato was a great advocate, subsisting between the different sexes, abstracted from all carnal appetites, and regarding no other objects but the mind

mind and its beauties: or it is even a sincere disinterested friendship, subsisting between persons of the same sex, abstracted from any selfish views, and regarding no other object than the person, if any such love or friendship has aught of a foundation in nature.

**PLATONIC YEAR**, or the great year, is a period of time determined by the revolution of the equinoxes, or the space wherein the stars and constellations return to their former places in respect of the equinoxes.

The Platonian year, according to Tycho Brahe, is 25816 years; according to Ricciolus, 25920; and according to Cassini, 24800. See the article *PRECESSION of the Equinoxes*.

This period once accomplished, it was an opinion among the ancients, that the world was to begin anew, and the same series of things to turn over again.

**PLATONISM**, the doctrine and sentiments of Plato and his followers, with regard to philosophy, &c. See the article *ACADEMIC*.

**PLATTOON**, or *PLOTTOON*, in the military art, a small square body of forty or fifty men, drawn out of a battalion of foot, and placed between the squadrons of horse, to sustain them; or in ambuscades, freights, and defiles, where there is not room for whole battalions or regiments.

Platoons are also used when they form the hollow-square, to strengthen the angles. The grenadiers are generally posted in platoons.

**PLEA**, in law, is what either party alleges for himself in court, in a cause there depending; and, in a more restrained sense, it is the defendant's answer to the plaintiff's declaration.

Pleas are usually divided into those of crown and common pleas. Pleas of the crown are all suits in the king's name, or in the name of the attorney-general on his behalf, for offences committed against his crown and dignity, and against his peace; as treason, murder, felony, &c. Common-pleas are such suits as are carried on between common persons, in civil cases. These pleas may be divided into as many branches as there are actions.

To an action there is either a general or a special plea: and here, a general plea is a general answer to the declaration, as in a debt or contract; the general plea is, that he owes nothing; in a debt upon bond, that it is not his deed, or he paid it on the day; in an action on a promise, that he made no promise; and in a trespass, not guilty. Special pleas are either in bar to the action brought, or in abatement of the writ on which the action is framed. All pleas are to be succinct, without any unnecessary repetitions, and must be direct and pertinent to the case.

**PLEADING**, in law, a speech uttered at the bar in defence of a cause: but, in a stricter sense, pleadings are all the allegations of the parties to a

suit, made after the declaration, till the issue is joined.

In this sense, they express what is contained in the bar, replication, and rejoinder; and not what is in the declaration itself. Hence, defaults in the matter of declaration are not confined within the mispleading.

**PLEBEIAN**, *Plebeius*, any person of the rank of the common people.

It is chiefly used in speaking of the ancient Romans, who were divided into senators, knights, and plebeians or commons.

**PLEDGE**, *Plegius*, in common law, a surety, either real or personal, which the plaintiff is to find, for prosecuting the suit.

**PLEDGERY**, or *PLEGGERY*, suretiship, or an answering for another person.

**PLEDGET**, *BOLSTER*, or *COMPRESS*, *Plumaceolus*, in surgery, a kind of flat tent, laid over a wound, to imbibe the superfluous humours, and keep it clean. See the article *WOUND*.

**PLEIADES**, *Vergiliae*, in astronomy, an assemblage of stars in the neck of the constellation Taurus. See *TAURUS*.

**PLENARTY**, in law, is when a church benefice is full of an incumbent.

**PLENARY**, something complete or full.

**PLENILUNIUM**, in astronomy, that phasis of the moon commonly called the full moon. See the article *MOON*.

**PLENIPOTENTIARY**, a person vested with full power to do any thing. See the article *EMBASSADOR*.

**PLENITUDE**, *Plenitudo*, the quality of a thing that is full, or that fills another.

In medicine, it chiefly denotes a redundancy of blood and humours. See the article *PLETHORA*.

**PLENUM**, in physics, denotes, according to the Cartesians, that state of things, wherein every part of space is supposed to be full of matter; in opposition to a vacuum. See *VACUUM*.

**PLEONASM**, *Pleonasmus Redundantia*, a figure in rhetoric, whereby we use words seemingly superfluous, in order to express a thought with the greater energy: such as, I saw it with my own eyes, &c.

This grammarians usually reckon a fault in discourse.

**PLEROTICS**, *Plerotica*, in medicine, a kind of remedies that are healing, or that fill up the flesh: otherwise called incarnatives and sarcotics. See the article *SARCOTICS*.

**PLETHORA**, in medicine, a greater redundancy of laudable blood and humours than is capable of undergoing those changes which must necessarily happen for the purposes of life, without inducing diseases.

A plethora is cured by venesection, exercise, watchings, a sharp and acrid diet, after due evacuation,

uations, and by a gradual omission of these evacuations.

**PLETHORIC**, *Plethoricus*, a person abounding with blood, or labouring under a plethora.

**PLEVIN**, *Plevina*, in law, the same with pledge. See **PLEDGE**.

**PLEURA**, in anatomy, a smooth, robust, and tense membrane, adhering to the ribs and to the intercostal muscles, and surrounding the whole cavity of the thorax. Its structure resembles two sacks, one of which surrounds one side of the thorax, and the other the other side, and each of them contains one of the two lobes of the lungs: from the conjunction of these two sacculi of the pleura, in the middle of the thorax, is formed the mediastinum.

**PLEURISY**, *πleuritis*, in medicine, a violent pain in the side, attended with an acute fever, a cough, and a difficulty of breathing.

This disorder effects all the parts of the internal integuments of the thorax, the whole of the pleura, and the whole of the mediastinum; and therefore, when it is seated in the membrane internally lining the ribs, it is called a true or internal pleurisy; but when it chiefly occupies the external parts, and only the intercostal muscles, and those above them, are affected, it is called a spurious or bastard pleurisy.

The pleurisy is most predominant between the spring and summer. It begins with chillness and shivering, which are soon succeeded by heat, thirst, inquietude, and the other common symptoms. After a few hours, the patient is seized with a violent pricking pain in one of his sides, about the ribs, which sometimes extends itself towards the shoulder-blades, sometimes towards the back-bone, and sometimes towards the fore-parts of the breast, and this is attended with frequent coughing. The matter which the patient spits, is at first little and thin, and mixed with particles of blood; but as the disease advances, it is more plentiful and more concocted, but not without a mixture of blood. The pulse is remarkably strong, and seems to vibrate like a tense string of a musical instrument; and the blood drawn from a vein, as soon as it is cold, looks like melted suet. As to the spitting, it is frequently absent, and hence pleurisies are distinguished into moist and dry.

As in all inflammatory fevers, so in this, too hot a regimen is to be shunned, both with respect to the bed-cloaths and the heat of the room; nor must the patient be exposed to the cold air, nor drink things actually cold. Hoffman observes, that all strong sudorifics and cathartics are hurtful; and that if the patient has three or four stools, the course of nature must not be stopped. The diet should be cooling, relaxing, slender, and diluting. Moistening things taken warm, are preferable to all others; and hence barley or oatmeal-gruel, sweetened with honey, and

also sweet whey, are proper. If the physician is called before the third day, Boerhaave directs a large quantity of blood to be let, from a wide orifice in a large vessel, and to fetch deep sighs, or cough, to promote its celerity; and the part affected should be rubbed gently at the same time, and the bleeding continued till the pain remits, or the patient is ready to faint. This should be repeated as often as the symptoms return, which it was intended to remove, and till the absence of the white inflammatory pellicle from the surface of the blood when cold, shews it is time to leave it off. This Huxham confirms by his own experience, and adds, that after the fourth day, bleeding is not safe; he also recommends fomenting the part, which often eases the pain, and terminates the disease; but if it is obstinate, he recommends slight scarifications, then cupping, and afterwards a blister on the same place; which has been successful, when the usual methods failed. The patient's body should be kept open, for which purpose emollient clysters are proper; and he should, at the same time, take large quantities of strong, diluting, aperient, and antiseptic liquors; for this purpose, take the leaves of jack-by-the-hedge, and white horehound, each two ounces; boil them in two pints of water, with which mix of the oxymel of squills eight ounces; of nitre, three drams; and of treacle-vinegar, one ounce; of this mixture let the patient, every quarter of an hour, take two ounces, as warm as possible.

Dr. Mead observes, on the treatment of this disorder, that after drawing as much blood as is necessary, draughts with fresh-drawn linseed-oil, are of great service for easing the cough; nitre, for allaying the heat; and for dissolving the fizy blood that obstructs the small canals, wild goat's blood and volatile salts; and, lastly, a blister laid on the part affected, in order to draw fourth the peccant humour.

A purulent abscess or empyema is sometimes formed in this disease, for the treatment of which, see **EMPYEMA**.

As to the bastard-pleurisy, Hoffman says that it is properly a kind of rheumatism, and does not require bleeding, unless the patient is plethoric, but a diaphoresis and a more free perspiration. Lancisi, however, advises plentiful bleeding in the arm, scarifying the part affected, and cupping; and during the cure, it is necessary to keep the body open, and the bowels free from spasms; for which purpose emollient clysters are proper, with oil of sweet-almonds.

**PLEUROPNEUMONY**, in medicine, a disease partaking of the nature both of a pleurisy and peripneumony. See the articles **PLEURISY** and **PERIPNEUMONY**.

**PLEXUS**, among anatomists, a bundle of small vessels interwoven in the form of net-work; thus a congeries

congeries of vessels within the brain is called plexus choroides, reticularis, or retiformis. See the article *Plexus CHOROIDES*.

A plexus of nerves is an union of two or more nerves, forming a sort of ganglion or knot.

*PLICA POLONICA*, in medicine, a disease of the hair, almost peculiar to Poland and Lithuania, and hence denominated polonica. It consists of a preternatural bulk of hair, which being firmly conglutinated and wrapped up in inextricable knots, and extended to a monstrous length, affords a very unseemly spectacle. When these are cut off, the blood is discharged from them, the head racked with pain, the sight impaired, and the patient's life frequently endangered.

*PLICATED*, something folded together, one part over another; as the leaves of certain plants, &c.

*PLINIA*, in botany, a genus of plants, the flower of which consists of a plane petal divided into five ovate concave segments; the filaments are numerous, hairy, and topped with small antheræ. The fruit is a large, globose, unilocular berry, containing one large, globose, smooth seed.

*PLINTH*, *ORLE*, or *ORLO*, in architecture, a flat square member, in the form of a brick.

It is used as the foundation of columns, being that flat square table, under the moulding of the base and pedestal at the bottom of the whole order. It seems to have been originally intended to keep the bottom of the original wooden pillars from rotting.

Vitruvius also calls the Tuscan abacus, plinth.

*PLINTH of a Statue*, &c. is a base, either flat, round, or square, that serves to support it.

*PLINTH of a Wall*, denotes two or three rows of bricks advancing out from a wall; or, in general, any flat high moulding, that serves in a front wall to mark the floors, to sustain the eaves of a wall, or the larmier of a chimney.

*PLOT*, in dramatic poetry, is sometimes used for the fable of a tragedy or comedy, but more particularly the knot or intrigue, which makes the embarrass of any piece. The unravelling puts an end to the plot.

*PLOT*, in surveying, the plan or draught of any field, farm, or manor, surveyed with an instrument, and laid down in the proper figures and dimensions.

*PLOTTING*, among surveyors, is the art of laying down on paper, &c. the several angles and lines of a tract of ground surveyed by a theodolite, &c. and a chain.

In surveying with the plain-table, the plotting is saved; the several angles and distances being laid down on the spot, as fast as they are taken. See the article *PLAIN-TABLE*.

But, in working with the theodolite, semicircle, or circumferentor, the angles are taken in degrees;

and the distances in chains and links; so that there remains an after-operation to reduce these members into lines, and so to form a draught, plan, or map; this operation is called plotting.

Plotting then is performed by means of two instruments, the protractor, and plotting-scale. By the first, the several angles observed in a field with a theodolite, or the like, and entered down in degrees in the field-book, are protracted on paper in their just quantity.

By the latter, the several distances measured with the chain, and entered down in like manner in the field-book, are laid down in their just proportion.

Under the articles protractor and plotting-scale, are found severally the use of their respective instruments in the laying down of angles and distances: in which also are given their use conjointly in the plotting of a field, surveyed either with the circumferentor or theodolite.

*PLOUGH*, in agriculture, a machine for turning up the soil, contrived to save the time, labour, and expence that without this instrument must have been employed in digging land, to prepare it for the sowing of all kinds of grain.

*PLOUGHMAN'S-SPIKENARD*. See the articles *BACCHARIS* and *CONYZA*.

*PLOUGHING*, or *PLOWING*, in agriculture, turning up the earth with a plough. Ploughing is principally either that of lays or fallows. Ploughing of lays, is the first cutting up of grass-ground for corn, and is a work commonly performed in January. The best time for doing it is when the land is wet, because the turf is then soft and tough, and will turn up without breaking. In the well turning of this consists the chief part of this sort of ploughing, which if rightly performed, will lay the turf so flat and true, that it can hardly be seen where the plough went. This, indeed, depends greatly upon the make of the plough; but if the earth-board does not turn the turf well, some nail upon it a small piece of wood, to take the upper part of the earth as it rises upon the earth-board, which causes it to fall with the grass side downwards. Ploughing of fallows, called also fallowing, is preparing land by ploughing long before it is ploughed for seed. See the article *FALLOWING*.

*PLUKENETIA*, in botany, a genus of plants producing male and female flowers, the corolla of each consists of four ovate patent petals; the male flower hath eight very short filaments, joining at their base, and topped with erect antheræ: the female flower hath a quadrangular germen, which becomes a depressed capsule, with keel-shaped angles, containing four cells, inclosing in each a roundish compressed seed.

*PLUM-TREE*, *Prunus*, in botany, a genus, whose flower consists of five roundish concave petals, inserted in the cup, with upwards of twenty stamina: the fruit is either a roundish or oval drupe,

drupe, with a longitudinal furrow, containing a compressed and acute pointed nut, with the furures standing out each way in an edge.

The plum tree, it is said, is a native of Armenia, and the country about Damascus, from whence they were first brought to Italy, and from thence to the other European countries.

As there are a considerable number of sorts of plums, we shall only mention a few of the best. 1. The perdigron plum. 2. The violet perdigron. 3. The white perdigron. 4. The myrobalan. 5. The green gage. 6. The drap d'or. 7. St. Catherine. 8. Mirabelle. 9. The damask violet. 10. The Orleans; this is the most common. 11. The imperial. 12. The mogul; these two last are good for baking, or sweet-meats: to which may be added, several other sorts, together with the damafon, floe, black and white bullace, which grow in the hedges, and are fit for tarts, the damafon in particular. They are propagated by inoculation, on wild plum stocks, and may be trained either for dwarf, espalier, wall, or standard trees. Plum trees do not only produce their fruit upon the last year's wood, but also upon cufsons or spurs, which come out of wood that is many years old; therefore on those againft walls, or espaliers, there is no necessity for shortening the branches, in order to obtain new shoots annually in every part of the tree (as is practised with peaches and nectarines) fince the more these trees are pruned, the more luxuriant they grow, until the strength of them is exhausted, and then they gum and spoil; therefore the best method to manage these trees, is to lay in their shoots horizontally as they are produced, at equal distances, in proportion to the length of their leaves, and during the growing season all foreright shoots should be displaced, and such as are to remain, should be gradually trained to the wall or espalier, which will not only render them beautiful, but also give to each an equal advantage of sun and air; and hereby the fruit will be always kept in a ductile growing state, which they seldom are when overshadowed with shoots some part of the season, and then suddenly exposed to the air and sun. Plum trees require a soil neither too moist or too dry, and those which are planted againft walls, should have a south-east, south-west, or west aspect, which is more kindly for them than the south exposure; and some of the hardier sorts may be planted againft a north aspect wall: plums gathered a day before they are eaten, and kept in nettles, are rather finer flavoured than fresh from the tree, when gathered in the middle of the day; they are in general moistening, laxative, and emollient (except the bullace and floe, which are astringent) they are also cooling, quench thirst, and create an appetite, and therefore they agree best with hot constitutions, but they do not at all agree with those that have weak stomachs. In those years that plums are very plenty, and conse-

quently much eaten by all sorts of people, fluxes of the belly generally abound, which often turn to bloody-fluxes, hence it appears that they always should be eaten with moderation, and should be quite ripe and sound.

*Brafilian-PLUM.* See the article SPONDIAS.

*Hog-PLUM.* See SPONDIAS.

**PLUMAGE**, the feathers which serve birds for a covering.

Plumage, is, in falconry, particularly understood of the feathers under a hawk's wing. Falconers give their hawks small feathers to make them cast, and these also they call plumage.

**PLUMB LINE**, among artificers, denotes a perpendicular to the horizon; so called as being commonly erected by means of a plummet. See PLUMMET.

**PLUMBAGO**, leadwort, in botany, a genus of plants, whose flower is monopetalous and funnel-shaped, the tube is cylindric and narrow at the top, and the limb is cut into five oval spreading segments: the stamina are five subulated filaments, topped with small oblong versatile antheræ: the seed is ovate and single, and included in the cup.

**PLUMBAGO**, mock-lead, in mineralogy, a fossile substance resembling lead-ore, much used in drawing, and for making pencils.

**PLUMBERY**, the art of casting and working lead, and using it in buildings, &c. See the article LEAD.

**PLUMBUM**, lead, in natural history. See the article LEAD.

**PLUMERIA**, in botany, a genus of plants, whose flower is monopetalous, and funnel-shaped, with a long tube, and divided into five oblong ovate segments; at the limb, in the center of the tube, are placed five subulated filaments, terminated with connivent antheræ. The fruit is composed of two long ventricose acuminate follicles, which are formed of one valve each, containing a number of oblong imbricated winged seeds. This genus, being natives of the West Indies, they require a hot-house in this climate for their preservation. They abound with a milky caustic juice, which is reckoned poisonous: in cutting off any of the branches of these plants, if the knife be not immediately cleaned, the juice will corrode it, and turn the blade almost black in a very little time, so as not to be cleaned off again, and if dropped upon linen, will cause it to wash in holes equal to aqua-fortis.

**PLUMMET**, **PLUMB-RULE**, or **PLUMB-LINE**, an instrument used by carpenters, masons, &c. in order to judge whether walls, &c. be upright planes, horizontal, or the like. It is thus called from a piece of lead, *plumbum*, fastened to the end of a chord, which usually constitutes this instrument. Sometimes the string descends along a wooden ruler, &c. raised perpendicularly on another; in which case it becomes a level. See LEVEL.

**PLUMMING**, among miners, is the method of using a mine-dial, in order to know the exact place of the work where to sink down an air-shaft, or to bring an adit to the work, or to know which way the load inclines when any flexure happens in it.

**PLUMOSE**, something formed in the manner of feathers, with a stem and fibres issuing from it on each side: such are the antennæ of certain moths, butterflies, &c.

**PLUNGER**, in mechanics, the same with the forcer of a pump. See the article **FORCER**.

**PLURAL**, *Pluralis*, in grammar, an epithet applied to that number of nouns and verbs which is used when we speak of more than one thing; or that which expresses a plurality or number of things. See **NUMBER**.

**PLURALITY**, *pluralitas*, a discrete quantity, consisting of two or a greater number of the same kind: thus we say a plurality of gods, &c.

Hence plurality of benefices, or livings, is where the same clerk is possessed of two or more spiritual preferments, with cure of souls.

**PLUS**, in algebra, a character marked thus +, used for the sign of addition. See the article **CHARACTER**.

**PLUSH**, in commerce, &c. a kind of stuff, leaving a sort of velvet knap, or shag, on one side, composed regularly of a woof of a single woollen thread and a double warp, the one wool, of two threads twisted, the other goats or camels hair; though there are some plushes entirely of worsted, and others composed wholly of hair.

**PNEUMATICS**, called also pneumatology and pneumatophy, among schoolmen, the doctrine and contemplation of spirits and spiritual substances, as God, angels, and the human soul, in which sense pneumatics are the same with what we otherwise call metaphysics. See the article **METAPHYSICS**.

**PNEUMATICS** is more commonly used among us, for that part of natural philosophy which treats of the nature and properties of the air.

**PNEUMONICS**, in pharmacy, medicines proper in diseases of the lungs, in which respiration is affected. Of this number are sulphur, lungwort, hyssop, ground-ivy, and colt's-foot: they are used in phthises, asthma, peripneumonies, pluries, &c.

**POA**, meadow-grass, in botany, a genus of plants, the corolla whereof is composed of two valves, of an ovato-acuminated figure; hollow, compressed, and somewhat longer than the cup, and without awns. It supplies the place of a pericarpium; and adheres every way to the seed, which is single, of an oblong figure, compressed and pointed at each end.

This is the most common of all grasses with us, and makes principally the green covering of most of our fields and meadows.

**POCKET**, in the woollen trade, a word used

to denote a larger sort of bag, in which wool is packed up to be sent from one part of the kingdom to another. The pocket contains usually twenty-five hundred weight of wool.

**POCK-WOOD**, *Guaicum*, in botany, 'see the article **GUAICUM**.

**POD**, *Siliqua*, among botanists, a kind of pericarpium, consisting of two valves, which open from the base to the point, and wherein the seeds are fastened along both the sutures or joining of the valves, such are the seed vessels of the cabbage, turnep, radish, stock, &c.

**PODAGRA**, in medicine, the gout in the feet. See the article **GOUT**.

**PODOMETER**, or **PEDOMETER**, the same with perambulator. See the article **PERAMBULATOR**.

**PODARIA**, in zoology, a division, order, or series of wingless insects, with short bodies, and not very numerous legs; comprehending the puceron, pediculus, acarus, spider, squill, &c. See the article **PUCERON**.

**PODOPHYLLUM**, ducks-foot, in botany, a genus of plants, the flower of which consists of nine orbiculated concave petals, plicated at their margin; the filaments are numerous, very short, and topped with large oblong erect antheræ: the fruit is an ovate, unilocular berry, crowned with the stigma, and contains a number of roundish seeds.

**POEM**, *Poema*, a composition in verse of a due length and measure. See the articles **VERSE** and **MEASURE**.

Poems are generally denominated from the subject matter, as the apobaterion, epibaterion, epinicion, epithalamium, genethliac, elegiac, satiric, epitaph, panegyric, lyric, pastoral, &c. and others, from the manner of narration, as epic, dramatic, &c. to which may be added odes, eclogues, and idylliums. To this head may also be referred several other compositions of a less serious kind, as the acrostic, enigma, anagram, cento, echo, &c. See each under its proper head: **APOBATERION**, &c.

The Abbé Du Bos observes, in regard to poems, that some are interesting in general, others in particular; that the beauties of execution alone do not constitute a good poem; that the defects of poems are less discernable than those of a picture; that our dislike falls only on the bad part of a poem; that every kind of poem has something particular in its style; that by the beauty of the style we must judge of poems; that it must be a long time before the merit of a good poem is distinguished; and finally, that the character of the poetic style has always decided the good or bad success of poems, even of those which by their length seem to have the greatest dependance on the oeconomy of the plan, on the distribution of the action, and on the decency of the manners.

**POESY**, the same with poetry. See the article **POETRY**.

**POET**, *ποιητης*, the author of a poem. See the article **POEM**.

**POETS ROSEMARY**. See the article **OSYRIS**.

**POETICAL**, something that relates to poetry or poets, in which sense we say poetical genius, poetical licence, &c.

**POETICAL JUSTICE**, is chiefly used in respect of the drama, to denote a distribution of rewards and punishments to the several persons at the catastrophe or close of a piece, answerable to the several characters they appeared in.

**PORTICAL rising and setting of the Stars**. The three kinds of rising and setting, viz. the cosmical, acronical, and helical, were made by the antient poets, referring the risings, &c. of the stars to that of the sun. See **COSMICAL**, &c.

**POETICS**, the doctrine of poetry, or the laws and rules of conducting pieces, or compositions of poetry, such is Aristotle's *Poetics*, a work much valued.

**POETRY**, the art of composing poems, or pieces in verse; or, as defined by Vossius, the art of representing actions in metre.

Vossius thinks that love was the first occasion of poetry, which is not improbable, considering that this affection is coeval with mankind, is universal, and naturally productive of poetry; yet it undoubtedly owes its increase and progress to religion: Dacier indeed calls it the offspring of religion; and it is certain, in the earliest ages of the world, that it was usual to sing hymns to the honour of the gods upon solemn festivals. Du Bos thinks that poetry has been employed in all ages, even by the most unpolished nations, to preserve the memory of past events. Its principal aim is to flatter our senses and imagination: for, according to Plato, it awakens the spiritual empire of the soul. Every kind of poetry charms us, in proportion to its object, says Du Bos; and to be very affecting, it ought to be very exact. It is not the same with poetry as with other arts, for an ignorant person may judge of poetry by the impression it makes on him: whence all men have a right to give their opinion of a piece of poetry, and this judgment ought to be founded on experience rather than on argumentation. Poetry is an art where every thing should please. It is not enough to exhibit nature, which in certain places and circumstances is rude and unpleasant, but the poet must chuse in her what is beautiful from what is not: whence a poet ought to chuse, for the subject of his imitation, something that is naturally affecting. There is a particular rhetoric for poetry, which consists in discerning very precisely what ought to be said figuratively, and what ought to be spoken simply; and in knowing where ornament is required, and where not: yet the style should be copious, and every species of writing in this art should have a diction proper to itself.

The qualifications then necessary for poetry, or those which form a good poet, are seldom found united in one person: he must have an extraordinary genius, great natural gifts, a wit just, piercing, solid, and universal; an understanding clear and distinct; an imagination neat and pleasant; an elevation of soul that depends not on art, or study, and which is purely a gift of heaven, and must be sustained by a lively sense and vivacity; a great judgment to consider wisely of things, and a vivacity to express them with that grace and abundance which gives them beauty. In fine, to accomplish a poet, is required a temperature of wit and fancy, of strength and sweetness, of penetration and delicacy; but, above all, he must have a sovereign eloquence, and a profound capacity. These are the qualities that must concur together to form the genius of a poet, and sustain his character.

The rules of poetry and versifying are taught by art, and acquired by study; but this force and elevation of thought, which Horace calls something divine, and which alone makes the poetry of any value, must be derived from nature; or, according to Aristotle, from some happy transports, to which that author gives the name of madness. Hence the critics conclude, the end of poetry is to please; its cause, either the excellence of the poet's genius, or a poetical fury and transport of the soul, manageable by the judgment; its matter, long and short syllables, and feet composed hereof, with words furnished by grammar; and its form, the arrangement of all these things in just and agreeable verse, expressing the thoughts and sentiments of the author after the manner already mentioned. But after all, how narrow are all these bounds, if we consider poetry in the light wherein the works of Homer and Virgil have set it. This, which is therefore distinguished by the name of the greater poetry, in contradistinction to the low and simple, or versification, consists principally in fiction, or the invention of fables, in the expressing of things by allegories, and metaphors, and in the inventing of actions, under which the truths which the poet has to teach, may be agreeably disguised.

**POINCIANA**, *Barbadoes flower-fence*, in botany, a plant which rises with a strait stalk ten or twelve feet high, which is covered with a smooth grey bark, and dividing into several spreading branches at the top, which are armed at each joint with two strong crooked spines, and are furnished with compound alated leaves, each being composed of six or eight pair of simple winged leaves, the lower pair being composed of four or five pair of lobes, the others gradually increasing in their number toward the top, where they decrease, and become smaller; the lobes are about three quarters of an inch long, and almost half an inch broad at their points, lessening gradually to their base: they are of a light green, and when bruised, emit a strong odour.

odour. The branches are terminated by loose spikes or flowers, the footstalk of each flower is near three inches long, the flower is composed of five unequal petals, four of which are roundish, and nearly equal; the fifth is larger, difform and crenated; the stamina are ten long setaceous filaments, terminated by oblong incumbent antheræ. The fruit is an oblong compressed pod, about three inches long, divided into three or four cells by transverse partitions, each containing one flattish irregular seed. The flowers are beautifully variegated with a deep red, or orange-colour, yellow and some spots of green.

This plant grows naturally in both Indies, and at Barbadoes it is planted in hedges; it is also called by some Spanish carnation, with us it is propagated by seeds, which should be sown in a hot bed, and when come up, transplanted singly into small pots, and placed in the tan-bed in the hot-house, where they must continually remain, observing to water and shift them when necessary.

**POINT**, a term used in various arts.

**POINT**, *Punctum*, in geometry, as defined by Euclid, is a quantity which has no parts, or which is indivisible. Points are the ends or extremities of lines. If a point be supposed to be moved any way, it will, by its motion, describe a line.

**POINT of contrary Flexure**. See the article **FLEXURE**.

**POINT**, in physics, the least sensible object of sight, marked with a pen; point of a compass, or the like. Of such points all physical magnitude consists. This physical point is the same with what Mr. Locke calls the point sensible, and which he defines to be the least particle of matter, or space, we can discern. He adds, that to the sharpest eye, this is seldom less than thirty seconds of a circle, whereof the eye is the center.

**POINT**, in grammar, a character used to mark the divisions of discourse. A point proper, is what we otherwise call a full stop or period.

**POINT**, in music, a mark or note antiently used to distinguish the tones or sounds; hence we still call it simple counter-point, when a note of the lower part answers exactly to that of an upper; and figurative counter-point, when any note is syncopated, and one of the parts makes several notes or inflections of the voice, while the other holds only one.

We still use a point, to raise the value of a note, and prolong its time by one half, e. g. a point added to a semibreve instead of two minims, make it equal to three; and so of the other notes. See the article **TIME**.

**POINT**, in astronomy, a term applied to certain points or places, marked in the heavens, and distinguished by proper epithets.

The four grand points or divisions of the horizon, viz. the east, west, north, and south, are called the

cardinal points. See the articles **HORIZON**, **EAST**, **WEST**, &c.

The zenith and nadir are the vertical points: the points wherein the orbits of the planets cut the plane of the ecliptic, are called the nodes: the points wherein the equator and the ecliptic intersect, are called the equinoctial points; particularly, that whence the sun ascends toward the north pole, is called the vernal point; and that by which he descends to the south pole, the autumnal point. The points of the ecliptic, where the sun's ascent above the equator, and descent below it, terminate, are called the solstitial point; particularly the former of them, the estival or summer-point; the latter, the brumal or winter-point.

**POINT of the Horizon**, or *Compass*, in navigation and geography. See the articles **HORIZON** and **COMPASS**.

**POINT**, is also used for a cape or head-land, jutting out into the sea: thus seamen say, two points of land are in one another, when they are so in a right-line against each other, as that the innermost is hindered from being seen by the outermost.

**POINT**, is also an iron or steel instrument, used with some variety in several arts.

Engravers, etchers, cutters in wood, &c. use points to trace their designs, on the copper, wood, stone, &c.

**POINT**, in the manufactories, is a general term, used for all kinds of laces, wrought with the needle; such are the point de Venice, point de France, point de Genoa, &c. which are distinguished by the particular oeconomy and arrangement of their points.

**POINT**, in poetry, denotes a lively brisk turn or conceit, usually found or expected at the close of an epigram.

**POINT-BLANK**, in gunnery, denotes the shot of a gun levelled horizontally. See the article **GUNNERY**.

**POINTED**, in heraldry. A cross pointed, is that which has the extremities turned off into points by straight lines.

**POINTING**, in grammar, the art of dividing a discourse, by points, into periods and members of periods, in order to shew the proper pauses to be made in reading, and to facilitate the pronunciation and understanding thereof.

**POINTING**, in war, the levelling a cannon, or mortar, so as to play against any certain point.

**POINTING**, among seamen, marking on the chart in what part or place the vessel is.

**POINTING the Cable**, in the sea-language, is untwisting it at the end, lessening the yarn, twisting it again, and making all fast with a piece of marline, to keep it from ravelling out.

**POISON**, in medicine, a malignant quality in some animal, vegetable, or mineral body, which renders it hurtful, and even mortal to those who take it.

To POISON a Piece, with gunners, is the same as to clog and nail it up.

POISON-TREE, *Toxicodendron*, in botany. See the article TOXICODENDRON.

POLAR, in general, something relating to the poles of the world, or poles of the artificial globes: thus we meet with polar circles, polar dial, polar projection, &c.

POLARITY, the quality of a thing considered as having poles; but chiefly used in speaking of the magnet.

POLE, *πολος*, in astronomy, one of the extremities of the axis, on which the sphere revolves.

These two points, each 90° distant from the equinoxial or equator, are, by way of eminence, called the poles of the world; and the extremities of the axes of the artificial globes, corresponding to these points in the heavens, are termed the poles thereof.

POLE, in spherics, a point equally distant from every part of the circumference of a great circle of the sphere, as the center is in a plane figure; or it is a point 90° distant from the plane of a circle, and in a line, called the axis, passing perpendicularly through the center. The zenith and nadir are the poles of the horizon; and the poles of the equator are the same with those of the sphere.

POLES of the *Ecliptic*, are two points on the surface of the sphere, 23° 30' distant from the poles of the world, and 90° distant from every part of the ecliptic.

POLES, in magnetics, are two points of a load-stone, corresponding to the poles of the world; the one pointing to the north, the other to the south. See the article MAGNET.

POLE, or *Vertex*, of a *Glass*, in optics, is the thickest part of a convex, or the thinnest of a concave-glass.

If the glass be truly ground, the pole will be exactly in the middle of its surface.

POLE, or POLAR STAR, is a star of the second magnitude, the last in the tale of *Ursa Minor*.

POLE-CAT, *Putorius*. See the article PUTORIUS.

POLEMICAL, in matters of literature, an appellation given to books of controversy, especially those in divinity.

POLEMONIUM, Greek-valerian, in botany, a plant, whose stalks rise near a foot and a half high; they are hollow and channeled, and furnished with winged leaves, composed of several pair of folliculi, placed alternately from the extremities of the stalks; the flowers come out in bunches, and are of a beautiful blue colour, each is composed of a wheel-shaped petal, with a short tube, and cut into five roundish segments at the extremity: they appear in May or June, and are succeeded by oval, acute pointed, three-cornered capsules, each having three cells, which are filled with irregular-point-

ed seeds. This plant is easily propagated by sowing the seeds in the spring.

The leaves of this plant are accounted deterfive.

POLEMOSCOPE, in optics, a kind of reflecting perspective-glass invented by Hevelius, who commends it as useful in sieges, &c. for discovering what the enemy is doing, while the spectator lies hid behind an obstacle.

POLIANTHES, the tuberose, in botany. See the article TUBEROSE.

POLICY, or POLITY, in matters of government. See the article POLITY.

POLICY, among letter-founders, denotes a certain proportion, observed among the letters that compose a fount; or a rule, whereby to regulate the number of each.

POLISHER, or BURNISHER, among mechanics, an instrument for polishing or burnishing things proper to take a polish.

The guilders use an iron polisher to prepare their metals before gilding, and the blood-stone to give them the bright polish after gilding.

POLISHING, in general, the operation of giving a gloss or lustre to certain substances, as metals, glass, marble, &c. See the articles METAL, GLASS, &c.

POLITICAL, in general, something relating to policy or government.

POLITICS, the first part of œconomy, consisting in the well governing and regulating the affairs of a state, for the maintenance of the public safety, order, tranquility, and morals.

POLITY, or POLICY, *πολιτεια*, denotes the peculiar form and constitution of the government of any state or nation; or the laws, orders, and regulations relating thereto.

Polity differs only from politics, as the theory from the practice of any art. See the articles LAW, GOVERNMENT, &c.

Some divide polity into agoronomy, or the regulations relating to mercantile affairs; and astynomy, or those which concern the judiciary government of the citizens: some add other branches, viz. those relating to ecclesiastical and military affairs.

POLL, a word used in ancient writings for the head: hence to poll, is either to vote or to enter down the names of those persons who give in their votes at an election.

POLL-MONEY, a capitation or tax, imposed by the authority of parliament on the head or person, either of all indifferently, or according to some known mark of distinction.

POLLARD, among hunters, a stag which has cast his horns.

POLLARD, or POLLENGER, in agriculture, signifies a tree that has been frequently polled, or lopped.

POLLEN, among botanists, the same as farina. See the article FARINA.

**POLLEX**, in anatomy, denotes either the thumb or great toe, according as either manus or pedis is added to it.

**POLLUTION**, in general, signifies defilement, or the rendering a person, or place, unclean or unholy.

**POLLUTION**, in medicine, a disease which consists in an involuntary emission of the seed in the time of sleep.

**POLLUX**, in astronomy, a fixed star of the second magnitude in the constellation Gemini, or the twins.

The same name is also given to the hindmost twin, or posterior part of the same constellation.

**POLVERINE**, in commerce, the ashes of the herb kali, preserved for the use of making glass.

**POLIACANTHA**, in botany, the same with the carduus, or thistle; which see.

**POLYADELPHIA**, the name of the eighteenth class in the Linnæan System of Botany, and consists of such plants whose flowers are hermaphrodite, and furnished with several sets of united stamina in each.

Of this class is the citron, orange, lemon, St. John's-wort, &c.

**POLYANDRIA**, the name of the thirteenth class of plants in the Linnæan System of Botany; comprehending such plants whose flowers are hermaphrodite, and furnished with many stamina, or male parts, in each; these always exceed the number of twenty, and are inserted in the receptacle.

To this class belong the piony, larkspur, aconite, columbine, helebore, with several other genera; the fruits of some of them are of a poisonous quality.

**POLIANTHUS**, in botany, a beautiful garden flower of the primrose kind; the varieties of this is innumerable, being produced from seeds, which should be sown in February, either in borders, boxes, or pots, and should have an east aspect, so as to be shaded from the heat of the day; in May they will be fit to be planted out for good, which should be in a shady border of strong rich earth, at about six inches asunder, and the succeeding spring they will shew their blossoms, when their goodness may be judged of.

As the properties of a good polyanthus are similar to those of the auricula, we, therefore, to prevent repetition, refer the reader to the article **AURICULA**, where they are fully explained.

**POLYCARPON**, in botany, a genus of plants, whose flower consists of five oblong, emarginated, very short petals, with three slender filaments topped with roundish antheræ; the fruit is an ovate unilocular capsule, opening with three valves, and contains a number of oval seeds.

**POLYCHREST**, in pharmacy, a medicine that serves for many uses, or that cures many diseases.

*Sal* **POLYCHREST**, a compound salt, made of equal parts of salt-petre and sulphur, laid on a red hot crucible.

**POLYCNEUMUM**, in botany, a genus of plants, whose flower hath no corolla; the cup is formed of five erect, lanceolated, pointed leaves, with three capillary filaments, topped with obtuse antheræ: the seed, which succeeds the flower, has scarce any covering, or at most only a very thin membrane.

**POLYGALA**, milk-wort, in botany, a genus of plants, producing papilionaceous flowers; the fruit is a turbinate heartshaped capsule, with two cells and two valves, each containing an ovate seed.

The polygala-vulgaris grows naturally in many parts of England; it hath a perennial woody root, with three or four trailing herbaceous stalks, furnished with linear spear-shaped leaves; the flowers are produced at the top of the stalks, and are of a blue, purple, or white colour.

It is supposed, that cattle which feed on this plant, give a greater quantity of milk than usual; and therefore it is reckoned good for nurses for the same purpose.

**POLYGALA VIRGINIANA**, rattle-snake-root, is a species of the former; it grows naturally in many parts of North-America. The root of this plant is perennial, and composed of several fleshy fibres, variously bent or contorted; it is yellowish without, but white within, and has an acrid bitterish taste, but somewhat aromatic: from the root arises three or four branching stalks, which grow erect, upwards of a foot high, and furnished with oblong, spear-shaped leaves, placed alternately; the flowers are produced in loose spikes at the ends of the branches, these are small and of a white colour.

The root of this species is looked upon, in America, as a specific against the bite of the rattle-snake, and has been long used by the Senega Indians for that purpose, which, if taken in time, is an infallible remedy: the Indians, when they travel in the woods, carry about them this root in powder, lest they should be bit by the rattle-snake, and whenever this happens, they take a quantity of the powder inwardly, and apply some of it to the part bitten, which is a certain cure, and of late years it hath been used by the inhabitants of Virginia in many disorders, which are occasioned by a thick fizy blood; so that the root of this plant, when its virtues are fully known, may become one of the most useful medicines yet discovered.

**POLIGAMIA**, in botany, the name of the twenty-third class of plants in the Linnæan System; comprehending those which produce (either upon the same or different plants) hermaphrodite flowers, and also flowers of one sex only, be it male or female, or flowers of each sex.

Of this class there are three orders or subdivisions, whereof the first consists of such polygamious plants, as contain the different kinds of flowers on different parts of the same plant, and hence called polygamia-monoetia; such are the plantain-tree, white-helebore,

bore, maple, orach, &c. the second order comprehends such polygamious plants as have their different flowers not on the same individual plant, but on distinct ones of the same species, and hence called polygamia dioecia; of this order are the ash, amber-tree, ginseng, &c. The third order, called polygamia-trioecia, comprehends such plants as have the polygamy on three distinct plants; this order contains but one genus, which is the fig-tree.

**POLYGAMY**, a plurality of wives or husbands, in the possession of one man or woman, at the same time.

**POLYGLOTT**, *πολυγλωττος*, among divines and critics, chiefly denotes a bible printed in several languages. In these editions of the holy scriptures, the text in each language is ranged in opposite columns. The first polyglott Bible, was that of cardinal Ximenes, printed in 1517, which contains the Hebrew text, the Chaldee paraphrase on the Pentateuch, the Greek version of the LXX. and the ancient Latin version. After this, there were many others, as the Bible of Justiniani, bishop of Nebio, in Hebrew, Chaldee, Greek, Latin, and Arabic; the Psalter by John Potken, in Hebrew, Greek, Ethiopic, and Latin; Plantin's polyglott Bible, in Hebrew, Chaldee, Greek, and Latin, with the Syriac version of the New Testament; M. le Jay's Bible, in Hebrew, Samaritan, Chaldee, Greek, Syriac, Latin, and Arabic; Walton's polyglott, which is a new edition of Le Jay's polyglott, more correct, extensive, and perfect, with several new oriental versions, and a large collection of various readings, &c.

**POLYGON**, in geometry, a figure with many sides, or whose perimeter consists of more than four sides at least: such are the pentagon, hexagon, heptagon, &c. See the articles **PENTAGON**, **HEXAGON**, &c.

**POLYGON**, in fortification, denotes the figure of a town, or other fortrefs.

The exterior or external polygon, is bounded by lines drawn from the point of each bastion, to the points of the adjacent bastions.

And the interior polygon, is formed by lines joining the centers of the bastions.

*Line of POLYGONS*, on the French sectors, is a line containing the homologous sides of the first nine regular polygons inscribed in the same circle; that is, from an equilateral triangle, to a dodecagon.

**POLYGONAL NUMBERS**, are so called, because the units whereof they consist may be disposed in such a manner, as to represent several regular polygons. See **NUMBER**.

The side of a polygonal number, is the number of terms of the arithmetical progression that compose it; and the number of angles is that which shews

how many angles that figure has, whence the polygonal number takes its name.

**POLYGONATUM**, Solomon's seal, in botany, is ranked by Linnæus among the convallaria. See the article **CONVALLARIA**.

The root of this plant is a famous vulnerary; for being applied in form of a poultice, it not only heals fresh wounds, but takes away the marks of bruises, &c.

**POLYGONUM**, knot-grass, in botany, a genus of plants, whose flower is apetalous, but the cup is of a turbinated form, coloured withinside, and divided into five oval segments at the limb; there is no pericarpium, but the seed, which is single, three-cornered, and pointed, is contained in the cup.

To this genus Linnæus has joined the bistorta, persecaria, and fagopyrum of Tournefort. An infusion of the common knot-grass is a valuable astringent medicine in hæmorrhages of all kinds.

**POLYGYNIA**, amongst botanists, an order or subdivision of a class of plants in the Linnæan system, comprehending such plants of that class as have a great number of pistils, or female organs of generation. see the articles **PISTIL** and **GENERATION**.

**POLYHEDRON**, in geometry, denotes a body or solid comprehended under many sides or planes.

A gnomonic polyhedron is a stone with several faces, wherein are described various kinds of dials. See the article **DIAL**.

**POLYHEDRON**, polyscope, in optics, is a multiplying-glass, or lens, consisting of several plane-surfaces disposed into a convex form. See the article **LENS**.

**POLYHISTOR**, a person of great and various erudition; whence

**POLYMATHY**, *πολυμαθια*, denotes the knowledge of many arts and sciences.

**POLYMNIA**, in botany, a genus of plants, producing compound radiated flowers; the hermaphrodite florets which form the disc are numerous, funnel-shaped, and quinquifid; the female florets compose the rays, and are ligulated and tridentated; the florets of the disc are abortive, but the female ones produce solitary, ovate, gibbous, and naked seeds, placed on a paleaceous, convex, imbricated receptacle.

**POLYMYTHY**, *πολυμυθια*, in poetry, a fault in an epic poem, when instead of a single mythos, or fable, there is a multiplicity of them.

**POLYNOMIAL**, or **MULTINOMIAL**, in algebra. See the article **MULTINOMIAL**.

**POLYOPTRUM**, in optics, a glass through which objects appear multiplied, but diminished.

**POLYPE**, or **POLYPUS**, in zoology, a small fresh-water insect of a cylindric figure, but variable, with very long tentacula.

There

There is scarce an animal in the world more difficult to describe than this surprising insect; it varies its whole figure at pleasure, and is frequently found beset with young in such a manner, as to appear ramose and divaricated; these young ones adhering to it in such a manner as to appear parts of its body.

When simple and in a moderate state as to contraction or dilatation, it is oblong, slender, pellucid, and of a pale reddish colour: its body is somewhat smaller towards the tail, by which it affixes itself to some solid body; and larger toward the other extremity, where it has a large opening, which is the mouth, around which are the tentacula, which are eight in number, and one usually extended to about half the length of its body. By means of its tentacula, or arms, as they are commonly called, expanded into a circle of more than half a foot diameter, the creature feels every thing that can serve it for food; and seizing the prey with one of them, calls in the assistance of the others, if necessary, to conduct it to its mouth.

The production of its young is different from the common course of nature in other animals; for the young one issues from the side of its parent in the form of a small pimple, which lengthening every hour, becomes, in about two days, a perfect animal, and drops from off its parent to shift for itself: but before it does, this, it has often another growing from its side; and sometimes a third from it, even before the first is separated from its parent; and what is very extraordinary is, that there has never yet been discovered among them any distinction of sex, or appearance of copulation; every individual of the whole species being prolific, and that as much if kept separate, as if suffered to live among others: but what is still even more surprising, is the reproduction of its several parts when cut off; for when cut into a number of separate pieces, it becomes in a day or two so many distinct and separate animals; each having the property of producing a head and tail, and the other organs necessary for life, and all the animal functions. There are several other species of this animal, most of which are found in our ditches. See plate LXXIII. where fig. 11. represents a cluster-polype, extending itself; and fig. 12. is the same polype after being soaked in water, and the tentacula, or branches laid straight.

POLYPETALOUS, among botanists, an epithet applied to such flowers as consist of several petals, or flower-leaves. See the article FLOWERS.

POLYPODIUM, polypody, in botany, a genus of cryptogamous plants of the fern kind, the fructifications of which are distributed in round spots on the under surface of the leaf.

The polypodies are not branched, but consist of single leaves, divided almost to the middle-rib into oblong jaggs, or segments. Both the root and

leaves are used in medicine, being a gentle cathartic, and recommended in obstructions of the viscera.

POLYPREMUM, in botany, a genus of plants, whose flower is monopetalous and rotated, with the limb cut into five segments; the stamina are four very short filaments, topped with roundish antheræ. The fruit is an ovate emarginated capsule, compressed at the top, containing two valves and two cells, which inclose a great number of seeds.

POLYPUS, or POLYPUS of the Heart, in medicine, a mass composed of various pellicles and fibres generated in the heart and large vessels.

POLYPUSES of the Lungs, are viscous excretions of the small glands, formed in the deeper branches of the aspera arteria, and frequently mistaken for pieces of the blood-vessels or lungs.

POLYPUS of the Nose, a fleshy excrescence, in the inside of the nostrils, which is of various sizes, and of different consistencies; sometimes these excrescences are soft, sometimes they are capable of elongation, and at other times they turn hard and rigid.

POLYPYRENEOUS, an appellation given to fruits, containing several kernels, or seeds.

POLYSCOPE, in optics, the same with polyhedron. See POLYHEDRON.

POLYSPASTON, in mechanics, a machine consisting of an assemblage of several pulleys; for the nature and force of which, see the article PULLEY.

POLYSPERMOUS, among botanists, such plants as have more seeds than four succeeding each flower, without any certain order.

POLYSYLLABLE, in grammar, a word consisting of more syllables than three; for when a word consists of one, two, or three syllables, it is called a monosyllable, dissyllable, and trisyllable.

POLYSYNDETON, in grammar and rhetoric, a figure whereby a redundancy of conjunctions, especially copulative ones, is used.

POLYTHEISM, in matters of religion, the doctrine or belief of a plurality of gods.

POLYTRICHUM, in botany, a genus of mosses, producing separate pedicles supporting male and female parts; the pedicles always growing out of the extremities of the stalks; the calyptra is conic, equal, and sometimes hairy; the antheræ is oblong; and in the female part the cup is coloured, and contains a slender jointed pistil.

POMATUM, an ointment made thus: Take of fresh hog's lard, and beat it into cream with rose-water, and scent it with oil of lemons, thyme, or the like. Pomatums are also occasionally perfumed with the odours of jessamines, oranges, jonquils, tuberoses, &c. They are principally used for pimples, and foulnesses of the skin.

POMEGRANATE-TREE, *Punica*, in botany, a genus of plants, whose flower consists of five roundish, erect, patent petals, inserted in the cup, which

which also contains a great number of capillary filaments topped with oblong antheræ. The fruit is a large globose apple, crowned with the cup, and formed into nine cells: the seeds are numerous, roundish, and succulent; the receptacle is membranaceous, and divides every cell into two parts.

There are several varieties of pomegranate trees, which grow naturally in Spain, Portugal, Italy, &c. as also in the West-Indies: these plants are cultivated in England more for the beauty of their fine scarlet flowers than their fruit, which rarely comes to perfection with us; they are easily propagated by laying down their branches in the spring, which in one year's time will take good root, and may then be transplanted where they are designed to remain; the best season to move them is just before they begin to shoot; the flowers always proceed from the extremity of the branches, which are produced the same year; for which reason all the weak branches of the former year should be cut out, and the larger lengthened according to their strength; the time for this operation is the beginning of October. The most admired sort is that which produces double flowers, the cup of which is the balauftine of the shops. Pomegranates are of various sizes, some being as big as large apples; the rind is pretty thick, hard and brittle; before it is ripe it is green and smooth, but afterward reddish and wrinkled, and last of all it becomes of a bay colour and yellowish within, and has an astringent taste; the pulp has a sweetish vinous flavour, though it is sometimes acid. This fruit differs but little in its medicinal virtues from quinces; the juice is good for weaknesses of the stomach and bowels, and removes nausea, vomitings, and fluxes; it is reckoned also a good cooler in inflammatory fevers: the rind of this tree, called malicorium, is more astringent than the juice, and has a bitterish austere taste; it is therefore much ordered in decoctions against gonorrhæas and fluxes, and often in astringent clysters. It will supply the place of oak bark for tanning leather, as well as of galls for making ink.

POMES, in heraldry, are green roundles, so called by the English heralds, who give distinct names to the different coloured roundles.

POMIFEROUS, in botany, an appellation given to apple-bearing trees. See the article APPLE.

POMME, or POMMETTE, in heraldry, is a cross with one or more balls or knobs at each of the ends.

POMMEL, or PUMMEL, in the manege, a piece of brass, or other matter, at the top and in the middle of the saddle-bow.

POMMEL, is also a round ball of silver, steel, or the like, fixed at the end of the guard, or grasp of a sword, to serve, in some measure, as a counterpoise.

POMPHOLYX, in the materia medica, a semi-metallic recriment, very nearly allied in its nature

to tutty; being a kind of flowers of zinc or calamine, sublimed higher than tutty, and carrying less of any metalline particles with it.

POMPION, in botany. See CUCURBITA.

POMUM, apple. See APPLE.

POMUM, among botanists, is also understood to be a fleshy or pulpy pericarpium, without a valve, and containing a capsule; therefore, by Linnæus, the fruit of the melon, cucumber, gourd, momordica, &c. is called pomum.

POND-WEED, *Potamogeton*, in botany. See the article POTAMOGETON.

PONE, in law, a writ whereby a cause depending in an inferior court, is removed into the king's bench, or common-pleas.

PONIARD, a little pointed dagger, very sharp edged: it is now little used, except among assassins.

PONS VAROLI, in anatomy, the upper part of a duct in the third ventricle of the brain. See the article BRAIN.

PONTEDERIA, in botany, a genus of plants, whose flower consists of six petals, which are divided, and form a kind of lip; the three upper ones are erect, and the three under reflexed; the filaments are six, and inserted in the corolla, and terminated with oblong antheræ. The fruit is a conic fleshy capsule, of a triangular figure, containing three cells, which are filled with roundish seeds.

PONTIFEX, PONTIF, or high priest, a person who has the superintendence and direction of divine worship, as the offering of sacrifices, and other religious ceremonies.

PONTIFICATE, is used for the state or dignity of a pontiff, or high priest; but more particularly, in modern writers, for the reign of a pope.

PONTON, or PONTOON, in war, denotes a little floating bridge made of boats and planks. The late invented ponton is of copper furnished with an anchor, &c. to fix it. To make a bridge, several of these are disposed two yards asunder, with beams across them; and over those are put boards or planks. They are also linked to each other, and fastened on each side the river by a rope run through a ring in each of their heads, and fixed to a tree or stake on either shore: the whole makes one firm uniform bridge, over which a train of artillery may pass.

PONT VOLANT, flying bridge. See the article BRIDGE.

POOL, is properly a reservoir of water supplied with springs, and discharging the overplus by sluices, defenders, weirs, and other caufeways.

Mill-POOL, a stock of water by whose force, &c. the motion of a mill is effected. See the article MILL.

POOP, *Puppis*, the stern of a ship, or the highest, uppermost, and hinder part of the ship's hull. See the articles STERN and SHIP.

POOR, in law, an appellation given to all persons

sons who are in so low and mean a condition, as that they either are, or may become, a burden to a parish.

Hence under the term poor, may be included those who are so through impotency; as the aged, the blind, the lame, the fatherless and motherless, persons labouring under sickness, or who are idiots, lunatics, &c. for all whom the overseers of the poor are obliged to provide.

There is also another kind of poor, on account of casualties and misfortunes; as decayed house-keepers, and those who have been ruined either by fire, water, robbery, or losses in trade, &c. all of whom, being able, are to be set to work, and otherwise relieved by the parish; and it is the same with respect to poor persons overcharged with children, disabled labourers, &c.

Before the reign of queen Elizabeth, we had few or no laws for the relief of the poor of this kingdom; but then a statute was made enacting, that the church-wardens of every parish, and two or more householders, are to be nominated and appointed yearly in Easter week, by two justices of the peace, as overseers of the poor; which said overseers shall meet once a month at the parish church, there to consider of proper ways to relieve the poor, &c. And with the assistance of the justices, they may make a rate on every inhabitant of the parish, and occupier of lands, houses, tithes; as also personal estate, to raise a stock for employing of the poor, relieving the impotent, and others not able to work, the placing poor children out apprentices, and erecting cottages for poor persons, &c.

POPE, *Papa*, the sovereign pontiff, or supreme head of the Romish church. The appellation of pope was antiently given to all Christian bishops, but about the latter end of the eleventh century, in the pontificate of Gregory VII. it was usurped by the bishop of Rome, whose peculiar title it has ever since continued.

POPLAR, *Populus*, in botany, a genus of trees producing male and female flowers on separate plants, growing in an oblong amentum, loosely imbricated, and composed of scales which are oblong, plain, and cut at their margin; the corolla has no petals, but consists of a monophyllous nectarium, turbinate at bottom, and tubulated at top; the stamina are eight very short filaments, topped with large, tetragonal antheræ. The fruit is an ovate bilocular capsule, containing a number of oval seeds covered with a hairy down. There are different species of this genus, as the white poplar or abele tree, the black poplar, the aspen tree, the Carolina poplar, &c. They are propagated either by layers, or large cuttings, planted in February, in a moist soil, where they will readily take root.

The best use these trees can be applied to, is for breaking off the westerly or northerly winds, and to be planted in such land where scarce any other tree

will thrive, for the advantage as will arise from its timber; for the wood of these trees, especially of the abele, is very good to lay for floors, where it will last many years; and for its exceeding whiteness, is by many persons preferred to oak; but being of a soft contexture, is very subject to take the impression of any thing hard and pointed, which renders it less proper for this purpose: it is also very proper for wainscoting rooms, being less subject to swell or shrink than most other sorts of wood; but for turnery ware there is no wood equal to this, for its exceeding whiteness; so that trays, bowls, and many other utensils, are made of it: and the bellows-makers prefer it for their use; as do also the shoe-makers, for heels for womens shoes; and of this wood the shoes are made which are worn by the peasants in France; it is also very good to make light carts; and the poles are very proper to support vines, hops, &c. and the loppings will afford good fuel.

POPLES, in anatomy, the inner part of a juncture, whereby the thigh bone is articulated with the tibia.

POPLITEA, in anatomy, a name given to the third vein of the leg, arising from the heel, where it is formed out of several branches, coming both from the heel and ancle. It lies pretty deep in the flesh, and ascending up to the ham, terminates in the crural vein.

POPPY, *Papaver*, in botany, a genus of plants, whose flower consists of four roundish, plane, patent petals, narrowest at the base, and alternately smaller; the filaments are numerous, capillary, and topped with oblong, compressed, erect antheræ. The fruit is a large capsule, crowned by a plain stigma, and opening in many holes under it: the seeds are numerous and very small, and the receptacles are longitudinal plicæ, of the same number with the rays of the stigmata, and growing to the sides of the capsule.

Of poppies there are several species; those cultivated in gardens are double and extremely beautiful, vying with the finest carnations for stripes and colours, and have nothing to discountenance their having a place amongst the most brilliant collection, but their short duration and offensive smell. They are propagated by sowing the seeds in autumn, or early in the spring, in the places where they are intended to flower. The heads of the fruit of poppies contain a milky juice, which may be collected in a considerable quantity, by slightly wounding them when almost ripe; this exposed for a few days to the air, thickens into a clammy mass, the same as opium, which is an extract from the heads of the white or Turkey poppy. See the article OPIUM. The seeds of the white poppy are used in emulsions, being cooling, and good in fevers and inflammatory distempers, as also for the stranguary and heat of urine.]

*Prickly POPPY.* See ARGEMONE.

*Spatling POPPY.* See CUCUBALUS.

POPULAGO, in botany, Tournefort's name for the caltha. See CALTHA.

POPULAR, *Popularis*, something that relates to the common people.

POPULUS, the poplar tree. See the article POPLAR.

PORCELAIN, or PURCELAIN, a fine sort of earthen-ware, chiefly manufactured in China, and thence called china-ware. See the article CHINA-WARE.

PORCELAIN-SHELL, *Porcellana*, in natural history, a genus of shell-fish, with a simple shell without any hinge, formed of one piece, and of a gibbose figure on the back; the mouth is long, narrow and dentated on each side; and the animal inhabiting it is a limax.

PORCH, in architecture, a kind of vestibule supported by columns; much used at the entrance of the ancient temples, halls, churches, &c.

PORCUPINE, *Histris*, in zoology, a very singular genus of quadrupeds, belonging to the order of the glires.

The fore-teeth of the porcupine are obliquely truncated, and it has no canine teeth: its ears are of a figure approaching to round, and the body is covered with prickles, or spines, and also with bristles, like those of a hog. The spines or quills, as they are commonly called, are of two kinds; some being shorter, thicker, stronger, and more sharp-pointed; and others longer, weaker, and more flexible: these last are a foot long, and compressed at the point. The spines of the first kind are white at the base, and of a dusky chestnut-colour on the upper part; and the latter kind are white at each extremity, and variegated with black and white in the middle. This terrible covering makes the creature appear much larger than it really is: it somewhat resembles the badger in shape; and its length, from the nose to the tail, is about two feet.

PORE, in anatomy, a little interstice or space between the parts of the skin, serving for perspiration. See the articles CUTIS and PERSPIRATION.

PORELLA, in botany, a genus of mosses, the anthera of which is oblong, and opening in holes on many sides; the other parts are too minute to be described.

POROPHYLLUM, in botany, the same with the cacalia of Linnæus. See the article CACALIA.

PORPESSE, in ichthyology, a species of the delphinus, with a coniform body, a broad back, and a subacute rostrum: it is a very large fish, frequently confounded with the dolphin, from which it is different.

PORPHYRY, in natural history, a kind of stone of a plain uniform mass, spotted with separate concre-

tions, of great hardness, giving fire with steel, not fermenting with acids, and very slowly and difficultly calcining in a strong fire.

PORRUM, the leek, in botany, a well known species of the cepa, or onion, with which it agrees both in botanical characters and medicinal virtues, being only accounted weaker. See the article ONION.

PORT, a commodious place situated on the sea-coast, or at the mouth of a river, screened from the wind and the enterprizes of an enemy, with depth of water sufficient for ships of burden, and where vessels lie by to load and unload.

Ports are either natural or artificial; the natural are those formed by providence, and the artificial such as are formed with moles running into the sea.

*Free-PORT*, in commerce, a port in which merchants of all nations may load and unload their vessels, without paying any duties or customs; as those of Leghorn, Genoa, &c.

PORT, among sailors, denotes the larboard, or left side of the ship: thus to port a helm, is to put it on the left side of the ship, that the ship may go to the right.

PORT-CRAYON, a pencil-case, which is usually four or five inches long, and contrived so as that the pencil may slide up and down. Its inside is round, and its outside is sometimes filed into eight sides or faces, on which are drawn the sector lines: sometimes it is made round both withoutside and within, and has its length divided into inches and parts of inches.

PORT-GREVE, or PORT-GRAVE, was formerly the principal magistrate of maritime towns. The chief magistrate of London was antiently called by this name, till Richard I. caused the city to be governed by two bailiffs; soon after which, king John granted the city a mayor.

PORT-HOLES, in a ship, are the holes in the side of the vessel, through which are put the muzzles of the great guns. These are shut up in storms, to prevent the water from driving through them. The English, Dutch, and French ships, have the valves, or casements, fastened at the top of the port-holes, and the Spanish vessels aside of them.

PORT-LAST, the same with the gun-wale of a ship. See GUN-WALE.

The yard is down a-port-last, when it lies down on the deck.

PORT-ROYAL, the name of two monasteries of Cistercian nuns, in the diocese of Paris; the one near Chevreuse, at the distance of five leagues from Paris, called Port-Royal of the Fields, and the other in Paris, in the Suburbs of St. James.

PORT-VENT, in an organ, is a wooden pipe which serves to convey the wind from the bellows to the sound-board. See the article ORGAN.

PORTA, or VENA-PORTA, in anatomy, one of the three primary veins of the human body.

PORTAIL,

## P O R

**PORTAIL**, in architecture, the frontispiece of a church, viewed on the side on which is the great door.

Portail is also used for the great door of a palace, castle, &c.

**PORTAL**, in architecture, a little gate where there are two gates of a different bigness; also a little square corner of a room cut off from the rest by the wainscot, and forming a short passage into the room.

The same name is also sometimes given to a kind of arch of joiners work before a door.

**PORTERAGE**, a duty paid at the custom-house to those who attend at the water-side, and belong to the package-office.

There are tables hung up ascertaining the porterage for landing and shipping goods.

**PORTICO**, in architecture, a kind of gallery on the ground, supported by columns, where people walk under covert.

Though this word is derived from *porta*, a gate, or door, yet it is used for any disposition of columns which form a gallery.

**PORTIO**, portion, a part or division of any thing: thus portio dura, and portio mollis, in anatomy, is a portion of the seventh pair of nerves of the brain.

**PORTION**, in law, a part or proportion, either of money given with a daughter, or of an inheritance.

**PORTION**, in the canon-law, is that proportion or allowance which a vicar receives out of a rectory or impropriation.

**PORTIONER**, is where a parsonage is served by two or more clergymen alternately, in which case the ministers are called portioners, because they have only their proportion of the tythes or profits of the living.

**PORTLAND-STONE**, is a dull whitish species of psadurium, much used in buildings about London: it is composed of a coarse grit, cemented together by an earthy spar; it will not strike fire with steel, but makes a violent effervescence with aquafortis.

**PORTLANDIA**, in botany, a genus of plants, whose flower is monopetalous; the tube is long and ventricosely funnel shaped, and the border is shorter than the tube, and cut into five acute segments: the stamina are five subulated filaments, topped with linear erect antheræ: the fruit is an oval bilocular capsule, having five furrows and five angles, and contains a number of imbricated compressed roundish seeds.

**PORTMANTEAU**, a cloak-bag of cloth, leather, &c. in which the cloak, linen, and other habiliments of travellers are disposed and laid on the horse's crupper.

**PORTRAIT**, **POURTRAIT**, or **POURTRAI-**

## P O S

**TURE**, in painting, the representation of a person, and especially of a face done from the life.

**PORTULACA**, purslane, in botany, a genus of plants, whose flower consists of five plane, erect, obtuse petals, larger than the cup, with many hairy stamina: the fruit is an ovate covered capsule, with one cell, containing many small seeds.

The common garden purslane is propagated by sowing the seeds in any of the summer months; and where it is suffered to shed, it will naturally come up the succeeding summer. It is cultivated for culinary purposes, and is reckoned a great assuager of choleric heat; it is also accounted good in the scurvy, and all cutaneous eruptions.

**PORUS**, in general, denotes a pore. See the article **PORE**.

**PORUS BILARIUS**, according to some, is the same with the hepatic duct; but others make a distinction between them, and observe, that the ductus hepaticus runs from the liver to the ductus cholelocus; and that the branches of this, distributed through the whole liver, make what are called the pori biliarii.

**POSE**, in heraldry, denotes a lion, horse, or other animal, standing still, with all his four feet on the ground.

**POSITION**, or **SITUATION**, in physics, an affection of place, which expresses the manner of any body's being therein.

**POSITION**, or *the Rule of False POSITION*, otherwise called *the Rule of FALSHOOD*, in arithmetic, is a rule, so called, because in calculating on several false numbers taken at random, as if they were the true ones, and from the differences found therein, the numbers sought is determined. This rule is either single or double.

Single position, is when there happens in the proposition some partition of numbers into parts proportional, in which case the question may be resolved at one operation, by this rule. Imagine a number at pleasure, and work therewith according to the tenor of the question, as if it were the true number; and what proportion there is between the false conclusion and the false proportion, such proportion the given number has to the number sought. See the article **PROPORTION**.

Therefore, the number found by argumentation, shall be the first term of the Rule of Three; the second number supposed, the second term; and the given number, the third. See the article **RULE of Three**.

Or the result is to be regulated by this proportion, viz. As the total arising from the error to the true total, so is the supposed part to the true one. Example: A, B, and C, designing to buy a quantity of lead, to the value of 140*l*. agree that B shall pay as much again as A, and C as much again as B; what then must each pay?

Now

Now suppose A to pay 10*l.* then B must pay 20*l.* and C, 40*l.* the total of which is 70*l.* but should be 140*l.* Therefore, if 70*l.* should be 140*l.* what should 10*l.* be?

Answer, 20*l.* for A's share, which doubled makes 40*l.* for B's share, and that again doubled gives 80*l.* for C's share; the total of which is 140*l.*

Double position, is when there can be no partition in the numbers to make a proportion. In this case, therefore, you must make a supposition twice, proceeding therein according to the tenor of the question. If neither of the supposed numbers solve the proportion, observe the errors, and whether they be greater or less than the supposition requires, and mark the errors accordingly with the signs + and —. See the article CHARACTER.

Then multiply contrarywise the one position by the other error, and if the errors be both too great, or both too little, subtract the one product from the other, and divide the difference of the products by the difference of the errors. If the errors be unlike, as the one + and the other —, add the products, and divide the sum thereof by the sum of the errors added together: for the proportion of the errors is the same with the proportion of the excesses or defects of the numbers supposed to be the numbers sought: or the suppositions and their errors being placed as before, work by this proportion as a general rule, viz. as the difference of the errors, if alike (or their sum, if unlike) to the difference of the suppositions, so either error to a fourth number, which accordingly added to or subtracted from the supposition against it, will answer the question.

POSITION, in geometry, is a term sometimes used in contradistinction to magnitude: thus, a line is said to be given in position, *positione data*, when its situation, bearing, or direction, with regard to some other line is given: on the contrary, a line is given in magnitude, when its length is given but not its situation.

POSITION, is also used for a thesis or proposition maintained in the schools. See the article THESIS.

POSITIVE, a term of relation sometimes opposed to negative: hence a positive quantity, in algebra, is a real or affirmative quantity, or a quantity greater than nothing; thus called, in opposition to a privative or negative quantity, which is less than nothing, and marked by this sign —. Positive quantities are designed by this character + prefixed or supposed to be prefixed to them. See the articles NEGATIVE, QUANTITY, and CHARACTER.

POSITIVE, is also used in opposition to relative or arbitrary: thus we say, beauty is no positive thing but depends on the different tastes of people. See the article RELATIVE.

POSITIVE DEGREE, in grammar, is the adjective in its simple signification, without any com-

parison; or it is that termination of the adjective, which expresses itself simply, and absolutely, without comparing it with any other: thus, *durus*, hard, *mollis*, soft, &c. are in the positive degree: but *durior*, harder, and *mollior*, softer, &c. in the comparative degree; and *durissimus*, hardest, and *mollissimus*, softest, &c. in the superlative degree. See the articles COMPARATIVE and SUPERLATIVE.

POSITIVE, in music, denotes the little organ usually placed behind or at the feet of an organist, played with the same wind and the same bellows, and consisting of the same number of pipes with the larger one, though those much smaller, and in a certain proportion: this is properly the choir-organ.

POSSE COMITATUS, in law, signifies the power of the county, or the aid and assistance of all the knights, gentlemen, yeomen, labourers, servants, apprentices, &c. and all others within the county that are above the age of fifteen, except women, ecclesiastical persons, and such as are decrepit and infirm.

POSSESSION, in law, the holding or occupying of any thing, either *de jure* or *de facto*.

Possession *de jure*, is the title a man has to enjoy a thing, though it be usurped and in the actual possession of another; or where lands are descended to a person, and he has not yet entered into them: and possession *de facto*, or actual possession, is where there is an actual or effectual enjoyment of a thing.

POSSESSIVE, in grammar, a term applied to pronouns which denote the enjoyment or possession of any thing, either in particular or in common: as *meus*, mine, and *tuus*, thine; *noſter*, ours, and *veſter*, yours. See the article PRONOUN.

POSSIBILITY, *Poſſibilitas*, in law, is defined to be any thing that is altogether uncertain, or what may or may not be, and is taken to be either near or remote.

A near possibility, is where an estate is limited to one after another's decease, whilst a remote possibility is something extraordinary, that is never likely to come to pass.

POSSIBLE, *Poſſibile*, is sometimes opposed to real existence, and understood of a thing which, though it does not actually exist, yet may exist; as a new star, another world, &c. which are particularly said to be physically possible.

It is also opposed to impossible, in which sense it is applicable to any thing that does not contradict itself, or involve contradictory predicates, whether it actually exist or not, as a man, fire, &c. these are also said to be logically possible.

POST, a courier or letter-carrier, or one who frequently changes horses, posted or placed on the road, for quicker dispatch.

The word is also applied to the houses where such a person takes up and lays down his charge.

**Penny-Post**, a post established for the benefit of London and the adjacent parts; by which any letter or parcel not exceeding sixteen ounces weight, or ten pounds value, is speedily conveyed to and from all parts within ten miles of London.

**Post**, in the military art, is any place or spot of ground fortified or not, where a body of men may make a stand and fortify themselves, or remain in a condition to fight an enemy. Hence it is said, that the post was relieved, the post was taken sword in hand, &c.

**Advanced Post**, is a spot of ground seized by a party to secure the army, and cover the posts that are behind.

**Posts**, in building, large pieces of timber placed upright in houses. The posts framed into bressummers for strengthening the carcase of a house, are called prick-posts, and the corner posts are called the principal posts.

Burning a little the ends of the posts that are to be set into the ground, is said to be an excellent method to prevent them from rotting.

**Posts**, in sculpture, are ornaments formed after the manner of rolls or wreathings; some of which are simple, and others enriched or flourished.

**POSTERIOR**, a term of relation implying something behind, or that comes after another, in which sense it is used in opposition to prior and anterior.

**POSTERN**, in general, is a small gate generally made in the angle of the flank of a bastion, or in that of the curtain, or near the orillon, descending into the ditch; by which the garrison may march in and out unperceived by the enemy, either to relieve the works, or to make private sallies, &c.

**POSTHUMOUS**, a child born after the death of his father, or taken out of the body of a dead mother, from whence it is frequently applied to the works of an author not published till after his decease.

**POSTIL**, a name anciently given to a note in the margin of the Bible, and afterwards to one in any other book posterior to the text.

**POSTING**, among merchants, the putting an account forward from one book to another, particularly from the journal or waste-book to the ledger. See the article **Book**.

**POSTIQUE**, in architecture, an ornament of sculpture superadded after the work is done. A table of marble, or other matter, is also said to be postique, when it is incrustated in a decoration of architecture, &c.

**POSTPONING**, putting any thing after or behind another, with regard to time.

**POSTSCRIPT**, an article added to a letter or memoir, containing something learnt or recollected after the piece was written.

**POSTULATE**, *Postulatum*, in mathematics, &c. is described to be such an easy, and self-evident supposition, as needs no explication or illustration to

render it intelligible; as, that a right-line may be drawn from one point to another. That a circle may be described on any center given, of any magnitude, &c. however, authors are not well agreed as to the signification of the term *postulatum*; some make the difference between axioms and postulata to be the same as that between the theorems and the problems; axioms, according to those authors, being indemonstrable theoretical truths. But others will have it, that axioms are primitive and common to all things, partaking of the nature of quantity, and which therefore may become the objects of mathematical science; such as number, time, extension, weight, motion, &c. and that postulata relate particularly to magnitudes, strictly so called, as to things having local extension, such as lines, surfaces, and solids; so that, in this sense of the word *postulatum*, Euclid, besides axioms, or those principles which are common to all kinds of quantities, has assumed certain postulata to be granted him peculiar to extensive magnitude. Hence several of the principles assumed in his elements, and ranked among the axioms by the moderns, are by Proclus ranked among the postulata, which has induced Dr. Wallis to judge, that the last of the two senses given to the term *postulatum* is most agreeable to the meaning of the ancient geometers.

**POSTURE**, in painting and sculpture, the situation of a figure with regard to the eye, and of the several principal members thereof with regard to one another, whereby its action is expressed.

**POTABLE**, *Potabilis*, something that may be swallowed by way of drink.

**POTAMOGETON**, pond-weed, in botany, a genus of plants, whose flower consists of four roundish, obtuse, concave, patent, and unguiculated petals, with four obtuse filaments topped with twin antheræ: there is no pericarpium; the seeds are four in number, roundish and acuminate, gibbous on one side, and compressed and angulated on the other.

This plant has a refrigerating virtue, and is recommended in the cure of old ulcers.

**POT-ASH**, the lixivious ashes of certain vegetables used in the making of glass, soap, &c. See the articles **GLASS**, **SOAP**, &c.

**POTATOE**, in botany, the English name for a species of the tuberose-rooted *solanum*. See the article **SOLANUM**.

*Culture of POTATOES*.—These roots being become a very common food among us, it may not be improper to mention their propagation and management: they may be encreased from seeds, but this is uncertain, as they are rarely perfect, and are more readily propagated by their roots, which multiply very fast if planted in a proper soil; therefore there is no necessity for practising any other method. The latter end of March is the season for planting them; the common way is either to plant the small roots entire,

entire, or to cut the large roots in pieces, leaving an eye or two to each piece; this method is very well in the contracted distance the gardeners commonly plant them, which is not above a foot asunder; but if the roots are chosen large and fair, without cutting, and planted at the distance of a foot and a half in the rows, and two feet and a half row from row, they will have room to extend their fibres, which will produce a greater quantity of roots, and larger, on the same space of ground, than in the common method: the depth they should be planted is about seven inches, but it is a wrong practice to plant them with a dibber, as it leaves a cavity underneath the plant; therefore they are best planted after the plough in the furrows, or where the spade is used, in the trenches.

When the plants are come up, the earth should be well stirred with a hoe, which will destroy the weeds, and let in the rains and dews more readily, which is of singular service to the plants, and being repeated a second time, will be all that is necessary, as the stalks will cover the ground and keep down the growth of weeds, whereby it will be rendered clean for any succeeding crop.

In autumn the haulm should be mowed down, and the roots taken up soon after and laid in a sheltered place, which the frost cannot easily penetrate, where they may be kept for use.

The soil in which potatoes thrive best is a light sandy loam, not too dry or too moist, which should be well wrought before planting, and a good quantity of rotten dung intermixed with it, which will make them grow luxuriantly.

**POTENT**, or **POTENCE**, a term for a kind of a cross, whose ends all terminate like the head of a crucifix. It is otherwise called the Jerusalem cross.

**POTENTIAL**, in grammar, an epithet applied to one of the moods of verbs.

The potential is the same in form with the subjunctive, and is, according to Ruddiman, implied in that mood, for which reason that grammarian rejects it: but others will have it to differ from the subjunctive in this, that it always implies in it either *possum*, *volo*, or *debeo*.

It is sometimes called the permissive mood, because it often implies a permission or concession to do a thing. See the articles **MOOD** and **SUBJUNCTIVE**.

**POTENTILLA**, cinquefoil, in botany, a genus of plants, whose flower consists of five roundish patent petals, inserted by their unguis into a monophyllous cup: the stamina are twenty subulated filaments, topped with long moon-shaped antheræ: there is no pericarpium; the receptacle of the seeds is roundish, small, and permanent, and is included in the cup, and surrounded with the seeds, which are numerous and acuminate.

The common cinquefoil, which grows naturally

in many parts of England, is accounted balsamic, vulnerary, and astringent; and has been given in all sorts of hæmorrhages, as well as in all kinds of fluxes of the belly; and is said to possess in a great measure the virtues of the Peruvian bark, whence the expressed juice of it is of great use in intermitting fevers.

**POTERIUM**, garden-burnet, in botany, a genus of plants, producing male and female flowers on the same spike; the corolla of the male flower is formed of a single petal, cut into four ovate, concave, patent segments, with a great number of capillary filaments, topped with roundish twin antheræ; the female flower is monopetalous and rotated: the fruit is a berry, the outer crust of which is formed of the indurate tube of the corolla, and contains two seeds.

This plant is propagated in gardens; the young tender leaves are put in sallads, and are likewise used for cool tankards in hot weather; it is reckoned to be cordial and alexipharmic, and the powder of the root it recommended against spitting of blood.

**POTHOS**, in botany, a genus of plants, whose flower-cup is a globose spatha; the corolla consists of four wedge-shaped, oblong, erect petals, having four broad erect filaments, topped with small twin antheræ: the fruit is a roundish aggregate berry, with two cells, each containing one roundish seed.

**POTION**, *Potio*, a liquid medicine, consisting of as much as can be drank at one draught.

**POTTERY**, the manufacture of earthen-ware, or the art of making earthen vessels.

*Chinese* **POTTERY**. See the article **PORCELAIN**.

**POTTLE**, an English measure containing two quarts. See the article **MEASURE**.

**POULTICE**, or **POULTIS**, a form of medicine also called a cataplasm. See the article **CATAPLASM**.

**POULTRY**, all kinds of domestic birds brought up in yards, as cocks, hens, capons, ducks, turkeys, &c.

**POUNCE**, gum sandaric pounded and sifted very fine, to rub on paper, in order to preserve it from sinking, and to make it more fit to write upon.

**POUNCE**, is also a little heap of charcoal-dust, inclosed in a piece of muslin or some other open stuff, to be passed over holes pricked in a work, in order to mark the lines or designs thereof on paper, silk, &c. placed underneath; which are to be afterwards finished with a pen and ink, a needle, or the like. This kind of pounce is much used by embroiderers, to transfer their patterns upon stuffs; by lace-makers, and sometimes also by engravers.

**POUNCES**, in falconry, the talons or claws of a bird of prey. See the article **FALCONRY**.

**POUND**,

**POUND**, *Libra*, a standard-weight, for the proportion and subdivisions of which, see the article **WEIGHT**.

**POUND**, also denotes a money of account; so called, because the ancient pound of silver weighed a pound troy. See the article **MONEY**.

**POUND**, among lawyers, denotes a place of strength, in which to keep cattle that are distrained, or put in for trespass, until they are replevied or redeemed.

**POUNDAGE**, a subsidy of 12*d.* in the pound, granted to the crown on all goods and merchandizes exported or imported; and if by aliens, one penny more.

**POURSUIVANT**, or **PURSUIVANT**, in heraldry, the lowest order of officers at arms.

**POWDER**, *Pulvis*, in pharmacy, a dry medicine well broken, either in a mortar, by grinding, or by chemical operations.

**POWDERINGS**, among builders, certain devices, serving to fill up vacant places in carved works.

**POWER**, *Potentia*, in physiology, the faculty of doing or suffering any thing.

**POWER**, in mechanics, denotes any force, whether of a man, a horse, a spring, the wind, water, &c. which being applied to a machine, tends to produce motion. See the articles **MACHINE** and **ENGINE**.

The intensity of a power is its absolute force; that is, its force, supposing its velocity equal to its weight: for its moving or acting force may be greater or less, according as its velocity is increased or diminished, in respect of that of the weight.

When we speak of the mechanical powers, the word power is taken in a very different sense from that above laid down; since, in this case, it signifies only an organ or instrument, whereby a power of a known intensity is made to act upon a weight: and therefore we must take care not to attribute any real force to any simple or compound machine, as many are apt to do, merely because the name power has been given to mechanical organs, not from their effect, but from the effect which the power produces by their means.

For how much soever the force of a power is thereby increased, in order to sustain or raise a weight far superior to it in intensity; yet this cannot be done without losing in space and time what is gained in force; contrary to what some have vainly imagined, because the vulgar commonly speak of a machine as they do of an animal; attributing that effect to the machine, which is only the effect of the power by means of the machine: thus, it is usual to say, such a machine raises such a quantity of water, or performs such and such work; when we should say, if we would speak philosophically, such a running stream, such a fall of water, the wind, or so many men, horses, oxen, &c. raise so

much water in such a time, &c. by means of such or such a machine. It were therefore to be wished, that the word power were to be confined to its proper sense, and not used to signify one of the mechanical organs; however, as it has been customary to use it in that sense, we have done so too, but withal thought proper to give the preceding caution.

The simple mechanical organs or powers are the lever, balance, axis in peritrochio, pulley, screw, wedge, and inclined-plane. See the articles **LEVER**, **BALANCE**, &c.

**POWER**, in law, signifies, in general, a particular authority, granted by any person to another to represent him, or act in his stead.

**POWERS**, in arithmetic and algebra, are nothing but the products arising from the continual multiplication of a number, or quantity, into itself: thus, 2, 4, 8, 16, 32, &c. are the powers of the number 2; and  $a$ ,  $a^2$ ,  $a^3$ ,  $a^4$ , &c. the powers of the quantity  $a$ ; which operation is called involution. See the articles **INVOLUTION** and **BINOMIAL**.

**POX**, or **SMALL-POX**, *Variolæ*, in medicine, a contagious disease appearing on the surface of the skin, which it covers with pustules, or ulcerous eruptions, that frequently leave scars behind them.

*French-Pox*, *Lues Venerea*, is defined a malignant and putridinous dyscrasy of all the humours, but especially of the serum and lymph, arising from a venereal taint received into the body; or, according to Sydenham, when a gonorrhoea has continued a long while, or long enough for the poisonous matter to make its way into the blood; or by astringents given unseasonably, it cannot make its exit, then the patient is infected with the French pox. See the article **GONORRHOEA**.

The buboes in the groin constitute the first degree of this distemper: then follow pains of the head, joints, of the shoulders, arms, and ancles, coming on by fits, but at no certain intervals, unless in the night, when the patient is warm in bed. See the article **BUBO**.

There are also scabs and scurfs in various parts of the body, which are as yellow as a honey-comb; sometimes they have large surfaces, answering the description which authors give of the leprosy. All these symptoms gradually increase, especially the pain, which becomes so intense that the patient is unable to lie in bed. Afterwards nodes or exostoses arise in the skull, skin-bones, and bones of the arms, which being attended with constant pain and inflammation, at length grow carious and putrefied: phagedenic ulcers likewise seize various parts of the body, but generally begin with the throat, then gradually creep by the palate to the cartilage of the nose, which they destroy, and the nose being destitute of its prop, falls down flat. The ulcers and pains daily encreasing, the patient sinks under the torment, and one member rotting away after another, is hurried into his grave.

**PRACTICE**, in arithmetic, or rules of practice, are certain compendious ways of working the rule of proportion, or golden-rule. See *RULE of Three*.

**PRÆ**, a Latin preposition, literally signifying *before*, and used in many words in our language, to denote the relation of priority; though they are often written with the common *e* instead of the *æ*; as præcession or precession, prædecessor or predecessor, &c.

**PRASIUM**, in botany, a genus of plants, whose flower is monopetalous and ringent, the upper lip is erect, roundish, and slightly emarginated; the lower lip is broad, trifid, and reflexed; the fruit consists of four roundish unilocular berries, placed in the bottom of the cup, and containing solitary roundish seeds.

**PRATIQUE**, or **PRATTIC**, in commerce, a negotiation, or communication, of commerce, which a merchant-vessel obtains in the port it arrives in, and the countries it discovers: hence to obtain a pratique, is to obtain a liberty to frequent a port, to go ashore, to buy and sell, &c.

Pratique is particularly used for a licence to traffic, granted to the master of a ship in the ports of Italy upon a bill of health; that is, a certificate that the place whence he came is not annoyed with any infectious disease.

**PRAYER**, in theology, a petition put up to God, either for the obtaining some future favour, or the returning of thanks for a past one.

**PREACHING**, in theology, the promulgation of the word of God in public; or the making a sermon, or public oration, on some passage in the sacred Scriptures, in order to inform the judgment, and mend the lives of the hearers.

**PREADAMITE**, a denomination given to the inhabitants of the earth who, according to some people, lived before Adam.

**PREAMBLE**, in law, the beginning of an act of parliament, &c. which serves to open the intent of the act, and the mischiefs intended to be remedied by it.

**PREBEND**, the maintenance a prebendary receives out of the estate of a cathedral or collegiate church. Prebends are distinguished into simple and dignitary; a simple prebend has no more than the revenue for its support; but a prebend with dignitary, has always a jurisdiction annexed to it.

**PREBENDARY**, an ecclesiastic who enjoys a prebend.

The difference between a prebendary and a canon is, that the former receives his prebend, in consideration of his officiating in the church; but the latter merely by his being received into the cathedral or college.

**PRECEDENT**, in law, a case which has been determined, and which serves as a rule for all of the same nature: thus the precedents of a court have

the force of laws, and no court will reverse a judgment contrary to many precedents.

**PRECENTOR**, a dignitary in cathedrals, popularly called the chantor, or master of the choir.

**PRECEPT**, in law, a command in writing sent by a chief justice, justice of the peace, &c. for bringing a person, record, or other matter, before him.

Precept is also used for the command or incitement by which one man stirs up another to commit felony, theft, &c.

**PRECESSION**, *Præcessio*, in astronomy, a term applied to a slow motion of the equinoctial points towards the west; that is, in the language of astronomers, *in antecedentia*, or contrary to the order of the signs. See *SIGN*.

This motion of the equinoctial points is occasioned by the poles of the world revolving round those of the ecliptic: in order to illustrate which, let DCH (plate LXXIII. fig. 13.) be the part of the earth's orbit, C its center, EC the axis of the ecliptic, E its pole, CP the axis of the earth, P its pole; through the points E and P draw the great circle EPA, meeting the ecliptic AL in A; the arch PA is equal to the inclination of the axis of the earth to the plane of the ecliptic, viz. the angle PCH, which is found by observation to be about  $66^{\circ} 30'$ , and therefore its complemental arch EP, or angle PCE =  $23^{\circ} 30'$ .

Through the pole P, from the point E, describe a lesser circle PFG, which will be parallel to the ecliptic; then, if the axis of the earth be directed at any particular time to P, it is found by observation of many years, that it will not be constantly directed to the point P, but in seventy-two years time be directed to some other point Q, so that the arch PQ = 1 degree; and therefore, in the space of  $360 \times 72 = 25920$  years, the point P, or pole of the world, will describe the circle PFG, about the pole of the ecliptic E, which revolution is called *annus magnus*, the great year; after which, the stars being re-instated in their proper places, the ancients imagined there would be a total renovation of all things.

The cause of this conical motion of the earth's axis was unknown to all the astronomers before Sir Isaac Newton's time, none of them being able to guess from whence it could proceed; but this sublime geometer soon investigated its cause, and demonstrated that it results from the laws of motion and gravity, that is, from the spheroidal figure of the earth; for if the earth was a perfect sphere, its axis would always continue parallel to itself, and consequently have no such motion. Hence the reason of the precession of the equinoctial points may be easily conceived; for the circle EPA, passing through both the pole of the ecliptic and equator, will be the solstitial colure, and A the solstitial point, when

when the axis of the earth points to P; but after seventy-two years, when it points to Q, then the great circle EQB will be the solstitial colure, and B the solstice. And because the equinoctial points are always ninety degrees distant from the solstices, they must consequently move in the same time, through the same arch, and the same way, viz. westward, or in antecedentia.

This retrograde motion, by carrying the equinoctial points to meet the sun in his apparent annual motion, makes him arrive at them sooner every year than he would do if those points continued immovable: and this arch of regression being 50'' a year, or one degree in seventy-two years, makes the equinoxes happen 20' in time sooner each year than they would otherwise do. And though this change be not sensible in a few years, yet these points are found to have a very different situation from what they had two thousand years ago.

By reason of this precession of the equinoctial points, the fixed stars seem to move towards the east, and thereby to have their longitude, which is always reckoned upon the ecliptic, from the vernal equinoctial point, encreased: and hence the constellations seem to have deserted the places allotted them by the antient astronomers; for instance, the beginning of the sign aries, which in Hipparchus's time, was near the vernal equinoctial point, and gave name to that point of the ecliptic, is now removed near a whole sign, or thirty degrees, eastward; so that aries is now where taurus used to be, taurus where gemini used to be, &c. and thus all the constellations of the zodiac have changed their antient places; but to avoid confusion, astronomers have thought fit to let the several portions of the ecliptic, where these constellations were at first observed to be, retain their old names; so that the vernal equinoctial point is still reckoned the first degree of aries. However, these portions of the ecliptic, where the constellations were at first, are called *anastara*, to distinguish them from the places where they now are, which are termed *stellata*.

**PRECIPITANT**, *Præcipitans*, in chemistry, is applied to any liquor, which, when poured on a solution, separates what is dissolved, and makes it precipitate, or fall to the bottom of the vessel.

**PRECIPITATE**, *Præcipitatus*, in chemistry, a substance which having been dissolved in a proper menstruum, is again separated from its solvent, and thrown down to the bottom of the vessel, by pouring some other liquor upon it.

**PRECIPITATION**, *Præcipitatio*, a process in chemistry, which is a kind of separation, whereby the particles of a body dissolved and suspended in any menstruous liquor, are detached therefrom, and fall down to the bottom of the vessel. These particles sometimes precipitate of their own accord, but oftener by the assistance of some other liquor added to the menstruum. So that precipitation is the re-

separating solid bodies from any fluid menstruum, wherein they are dissolved, by the addition of a third body, which, counteracting the power of the menstruum, causes that which was dissolved to regain its solid form, and subside in the state of a powder.

**PRECONTRACT**, in law, properly signifies a contract made before another, but is chiefly applied to marriage-contracts.

**PRECORDIA**, *Præcordia*, in anatomy, a general name to the parts situated about the heart, in the fore-part of the thorax; as the diaphragm, pericardium, and even the heart itself, with the spleen, lungs, &c.

**PREDESTINATION**, in general, signifies a decree of God, whereby, from all eternity, he ordained such a concatenation of causes as must produce every event by a kind of fatal necessity, and maugre all opposition. See the articles **FATE**, **NECESSITY**, &c.

Nothing has occasioned more disputes than this thorny subject of predestination; the Lutherans speak of it with horror, whilst the Calvinists contend for it with great zeal; the Molinists and Jesuits preach it down as a most dangerous doctrine, whilst the Jansenists assert it as an article of faith; the Arminians, Remonstrants, and Pelagians, are all avowed enemies to predestination.

**PREDETERMINATION**, in philosophy, that concurrence of God, which determines men in all their actions, both good and evil; and this concurrence, or influence, is called physical predetermination, or premotion: for divines maintain, that God has no share in the sins of mankind, inasmuch as he only affords his concurrence to the physical part of their actions, not to the moral part.

**PREDIAL TITHES**, are those that are paid of things arising and growing from the ground only; as corn, hay, fruit, &c. See the article **TITHES**.

**PREDICABLE**, among logicians, denotes a general quality which may be predicated, or asserted of several things: thus animal is predicable of mankind, beasts, birds, fishes, &c.

**PREDICAMENT**, among logicians, the same with category. See **CATEGORY**.

**PREDICATE**, *Prædicatum*, in logic, that part of a proposition which affirms or denies something of the subject: thus, in these propositions, *snow is white*, *ink is not white*, whiteness is the predicate which is affirmed of snow, and denied of ink.

**PREDICATING**, in logic, the act of affirming or denying something of a thing, as a man is not an angel; body is a substance, &c.

**PREDICTION**, *Prædictio*, the foretelling of what is to come, either by divine revelation, art, or conjecture.

**PREDOMINANT**, *Prædominans*, that which prevails, or has some superiority, over another thing.

**PREENING**, in natural history, the action of birds dressing their feathers, to enable them to glide the more readily through the air, &c.

**PRE-EXISTENCE**, *Præ-existentia*, the state of a thing actually in being before another.

**PREFACE**, *Præfatio*, something introductory to a book, to inform the reader of the design, method, &c. observed therein; and generally whatever is necessary to facilitate the understanding of a book.

**PREFECT**, *Præfectus*, in ancient Rome, one of the chief magistrates, who governed in the absence of the kings, consuls, and emperors.

**PREGNANCY**, *Graviditas*, the state of a woman who has conceived, or is with child. See the articles **GENERATION**, **CONCEPTION**, &c.

**PREJUDICE**, *Præjudicium*, does not mean a judgment merely as prior to another in respect of time, but as being passed before the things were duly considered and fully understood. Hence prejudice is sometimes called anticipation, and a preconceived opinion; and makes one of the many causes of error. See **ERROR**.

**PRELATE**, an ecclesiastic raised to some eminent and superior dignity in the church; as bishops, archbishops, patriarchs, &c. See **BISHOP**, &c.

**PRELIMINARY**, in general, denotes something to be examined and determined, before an affair can be treated of to the purpose.

**PRELUDE**, *Præludium*, in music, is usually a flourish or irregular air, which a musician plays off-hand, to try if his instrument be in tune, and so lead him into the piece to be played. Very often the whole band in the orchestra run a few divisions, to give the tune.

**PREMISES**, or **PREMISSSES**, *Præmissæ*, in logic, an appellation given to the two first propositions of a syllogism, as going before, or preceding the conclusion.

**PREMISES**, in law, properly signifies the land, &c. mentioned in the beginning of a deed. See the article **DEED**.

**PREMIUM**, or **PRÆMIUM**, properly signifies a reward or recompence; but it is chiefly used in a mercantile sense for the sum of money given to an insurer, whether of ships, houses, lives, &c.

**PREMONSTRATENSES**, in church-history, a religious order, instituted by St. Norbert, about the year 1119.

**PROMOTION**, *Præmotio*, the same with predetermination. See the article **PREDETERMINATION**.

**PREMUNIRE**, or **PRÆMUNIRE**, in law, is taken two ways; either for a writ, or for the offence for which it is granted.

Formerly the church of Rome carried its pretended right of supremacy to such a height, that several statutes were made to check and restrain the growing power of the pope; but more especially stat. 16 Richard II. c. 5. commonly known by the

name of the statute of premunire, which ordains the punishment of offenders on this statute to be this; that they should be out of the king's protection, attached by their bodies, i. e. imprisoned at the king's pleasure, and lose their lands, goods, and chattels.

Premunire is now chiefly used for the above punishment, which is incurred not only by those who assert the pope's supremacy; but also by those who refuse to take the oath of allegiance, or of the king's supremacy, &c.

**PRENANTHES**, in botany, a genus of plants, the compound flower of which is not imbricated, but consists of five or eight equal hermaphrodite florets, placed in a simple round order; these are monopetalous, ligulated, and quadritentated, and are succeeded by solitary heart-shaped seeds, crowned with hairy down, and contained in the cup.

**PRENOMEN**, *Prænomen*, among the antient Romans, a name prefixed to their family-name, answering to our christian name: such are Caius, Lucius, Marcus.

**PREPARATION**, *Præparatio*, in mathematics, something preparatory to the demonstration of a proposition. Thus if a proposition in geometry is to be demonstrated, the preparation consists in drawing certain lines; and if a proposition in arithmetic, in some computation to be previously made to come at the demonstration.

**PREPARATION**, in pharmacy, &c. the manner of preparing and managing any medicine, in order to fit it to serve the purposes for which it is intended.

**PREPARATION**, in anatomy, the art of preserving the parts of animals for anatomical uses; which is done either by drying them thoroughly, or putting them in a proper liquor.

**PREPENSED**, *Præpensus*, in law, denotes forethought: thus when a man is slain upon a sudden quarrel, if there was malice prepensed formerly between them, it makes it murder.

**PREPOSITION**, *Præpositio*, in grammar, one of the parts of speech, being an indeclinable particle which yet serves to govern the nouns that follow it; such as *per*, *pro*, *propter*; and *through*, *for*, *with*, &c.

F. Buffier allows it to be only a modificative of a part of speech, serving to circumstantiate a noun.

**PREPUCE**, *Præputium*, in anatomy, the foreskin; being a prolongation of the cutis of the penis, covering the glans.

**PREROGATIVE**, *Prærogativa*, a pre-eminence which one person has over another.

**PRESAGE**, *Præsagium*, in antiquity, denotes an augury, or sign of some future event; which was chiefly taken from the flight of birds, the entrails of victims, &c.

Among physicians, the term presage is sometimes used for prognostic sign.

**PRESBYTA**, *πρεσβυτης*, in optics, a person whose eyes being flat, can see distant objects distinctly, but those near, confusedly; which defect of sight got this appellation, because old people are naturally subject to it.

Spectacles, or convex-glasses, are the only remedy for this defect; for if these are well fitted to the degree of flatness of the eyes, they cause the rays of light to converge in such a manner from near objects, as to make them fall exactly on the retina, and thereby produce distinct vision.

**PRESBYTER**, in the primitive christian church, an elder, one of the second order of ecclesiastics; the other two being bishops and deacons.

Presbyter, or elder, is a word borrowed from the Greek translation of the Old-Testament, where it commonly signifies ruler or governor; it being a note of office and dignity, not of age; and in this sense, bishops are sometimes called presbyters in the New-Testament.

**PRESBYTERIANS**, a sect of protestants, so called from their maintaining that the government of the church, appointed in the New-Testament, was by presbyteries; that is, by ministers and ruling elders, associated for its government and discipline.

The presbyterians affirm, that there is no order in the church, as established by Christ and his apostles, superior to that of presbyters; that all ministers being ambassadors of Christ, are equal by their commission; and that elder or presbyter, and bishop, are the same in name and office: for which they allege, *Acts* xx. 28, &c.

The only difference between them and the church of England, relates to discipline and church-government.

**PRESCIENCE**, in theology, fore-knowledge, or the knowledge which God has of events before they come to pass.

**PRESCRIPTION**, in law, is a right or title acquired by use and time, introduced for assuring the property of effects, in favour of persons who have for a certain time had them in their possession.

**PRESCRIPTION**, in medicine, is the assigning a proper and adequate remedy to a disease, from an examination of its symptoms, and an acquaintance with the virtues and effects of the *materia medica*.

**PRESENT**, *Præsens*, in grammar, the first tense of a verb, expressing the present time, or that something is now performing; as *scribo*, I write, or am writing. See the article **TENSE**.

**PRESENTATION**, in law, the act of a patron offering his clerk to be instituted in a benefice of his gift, the same being void.

**PRESENTÉE**, the clerk presented to a benefice by the patron.

**PRESENTMENT**, in law, a denunciation of jurors, or a justice of the peace, or other officers, without any information of an offence inquirable by the court, to which it is presented; or it may be

said to be an information made by the jury in a court before a judge, who has authority to punish any offence committed contrary to law; and it is what the grand jury finds and presents to the court, without any bill of indictment delivered: yet it is afterwards reduced into the form of an indictment.

**PRESEPE**, or *PRÆSEPE*, in astronomy, the name given to three nebulous stars in the breast of Cancer. See the article **CANCER**.

**PRESERVATION**, in general, denotes the art of preserving things in a state of perfection; or, at least, from being so far corrupted and spoiled, as to be no longer useful.

Animal substances are preserved by curing, pickling, drying, or chemical preparation. See the articles **CURING**, **PICKLING**, &c.

For the method of preserving corn in granaries, see the articles **CORN** and **GRANARY**.

Fruits may be long preserved in spirit of wine, first well saturated with the skins and tinging parts of those fruits; and many may be tolerably preserved in perfectly fermented liquors, which generate no more air.

The more solid vegetable substances may be preserved by gently drying in the sun, shade, or other slack heat. Thus peas or beans may be dried young in a slack oven in their proper season, and may afterwards be boiled in the winter, and will eat young and tender, as if just gathered.

The ways of preserving fruits, both dry and moist, with sugar, are now universally known; and there are, in the several ways, many secrets, in the hands of particular artists, which it would be well to have generally known. See the article **FRUIT**.

As for the methods of curing and preserving vegetable juices and liquors, by decoction, inspissation, fermentation, clarification, matching, &c. See the articles **DECOCTION**, **INSPISSATION**, &c.

**PRESERVATIVE**, among physicians, denotes a medicine taken by way of precaution; or, to secure a man from a disease that threatens him.

The principal preservatives, according to Boerhaave, are abstinence, quiet, drinking warm water; and, after this, a gentle and continued motion till the first appearance of sweat; then a profound sleep, the body being well covered.

In the time of a plague, preservatives are very necessary against the contagion of the air.

Generous wines, cardiacs, and sudorifics, are also powerful preservatives.

**PRESIDENT**, *Præses*, an officer created or elected to preside over a company, in contradistinction to the other members, who are called residents.

**PRESS**, *Prelum*, in the mechanic arts, a machine of wood, or iron, serving to squeeze any body very close.

Thus, let AB (plate LXXV. fig. 1.) be a cheese-press; where CE, FG, are levers, moveable

Fig. 1. A Cheese Press.

Fig. 4. Printing Press.

Fig. 2. The Common Wine Press.

Fig. 3. A Press to make Very fine or the square Apples.

Fig. 3. The Great Wine Press.

Fig. 5. Rolling Press.

able about the points, D, E, F, G, by applying the hand at C; S, the stone, or weight; and H, the cheese to be pressed.

Now, if  $CD=5$ ,  $DE=2$ ,  $FG=6$ ,  $GH=2$ ,  $FR=1$ ,  $FH=4$ ; then in the lever CE, D is the fulcrum. Call the power at C, 1; then the force at E or F is  $\frac{5}{2}$ . And in the lever FG, whose fulcrum is G, if the power at F be 1, the force at R is  $\frac{6}{2}$ ; and therefore the power at C is to the weight S, as 1 to  $\frac{5}{2} \times \frac{6}{2}$ , or 3. Also the weight of the stone at R is to the pressure at H, as 2 to 5, or 1 to  $\frac{5}{2}$ ; and the power at C is to the pressure at H, as 1 to  $3 \times \frac{5}{2}$ , or  $7\frac{1}{2}$ .

Presses usually consist of six pieces; two flat smooth planks, between which the things to be pressed are laid; two screws or worms fastened to the lower plank, and passing through two holes in the upper; and two nuts in form of an S, that serve to drive the upper plank, which is moveable, against the lower, which is fixed.

Presses used for expressing liquors are, in most respects, the same with the common presses, only the under plank is perforated with a great number of holes for the juice to run through. Others have only one screw, or arbor, passing through the middle of the moveable plank, which descends into a kind of square box, full of holes, through which the juices flow, as the arbor is turned.

But that the reader may be enabled to form a more distinct idea of these presses, we shall give a draught of the common and great wine-press, used for squeezing the juice out of grapes.

A B (plate LXXV. fig. 2.) is the base or pedestal and other supporters of the common wine-press. C, C, the cheeks, which are upright beams, the lower extremities of which are sunk in the earth, where they are strongly fixed by cross bars and masonry: they are traversed at top by two beams, the lowermost of which is the nut, or receptacle of the screw. D is the screw with its wheel. E the bearer, or large piece of timber on which the wheels rest, in order to sink the beams crossing the planks that cover the grapes. F. G, G, the maye, or planks on which the grapes are disposed, in order to be squeezed: these planks are cut in notches, to receive the liquor and convey it to a vessel appropriated to receive it. The maye is supported on a massive work of masonry. H is the wheel that serves to force down the screw and bearer upon the grapes, which are laid upon the maye in a square heap: this it does by winding off the cord from the wheel of the screw D, by which means the screw and the bearer, E, are pressed down upon the grapes, which are usually covered with cross-beams, reared above each other. I is a leather pipe, terminating in two wooden tubes, for conveying the wine from one piece to another. K is a large bellows to agitate the wine when it has settled into an even surface in both vessels. L the same bellows in profile. M is a

large fountain, which affords a quick flow. And N is a stopple to close the vessel newly filled, and prevent the wine from running over, upon withdrawing the wooden tube.

A B (fig. 3.) represents the base and other supports of the great wine-press; C, C, &c. the cheeks or side-beams; D, D, great beams, two in number at least, and frequently four, or even six; E the screw; F the nut of the press; G the wheel, which by the help of five or six men, turns the screw; and H the cage, which is an assemblage of several strong pieces of timber formed into a square, and lined with masonry within. This cage is ten feet long, and four and a half broad on each side, and may be either raised out of, or sunk into, the pit of masonry work I; from whence it is exhibited as ascending in the figure referred. It usually weighs three thousand pounds; and being suspended in the manner represented, forms, in conjunction with the screw, a lever of an immense force, for squeezing down a bearer upon grapes placed upon the maye K, as in the former figure. See the article WINE.

As to cyder-presses, the best and least chargeable is that called the box-press (fig. 4.) with which you may squeeze apples, pears, grapes, or any other fruit to make cyder, perry, wine, or verjuice: for, as one end of the box terminates in a moveable beam, which is worked by a wheel and a screw in the usual manner; so there are holes in the side of the box, through which the juice flows, by a spout, into a vessel designed to receive it. See the article CYDER.

PRESSURE, or PRESSION, in general, denotes the squeezing a thing close together.

PREST, a duty in money paid by the sheriff upon his account in the exchequer, for money remaining in his hands.

PREST-MONEY, the money given to new 'listed soldiers, so called because it binds those who receive it, to be ready at all times.

PRESTATION, signifies the payment of a certain sum by archdeacons, and other clergymen, annually to their bishop.

PRESTER, in physiology, a meteor consisting of an exhalation, thrown from the clouds downwards with such violence, as by the collision it is set on fire.

It differs from the thunderbolt in the manner of its inflammation, and its burning and breaking every thing it touches with great vehemence.

PRESUMPTION, in law, signifies an opinion or belief of a thing.

PRESUMPTIVE HEIR, the same with heir at law. See the article HEIR.

PRETENCE, or *Escutcheon of PRETENCE*, in heraldry. See the article ESCUTCHEON.

PRÆTERITE, *Præteritum*, in grammar, a tense which expresses the time past, or an action completely finished; as *scripsi*, I have wrote, &c.

**PRETERITION**, in rhetoric, a figure whereby, in pretending to pass over a thing untouched, we take a summery view of it.

**PRETEXT**, a colour or motive, whether real or feigned, for doing something.

**PRETOR**, or **PRÆTOR**, a magistrate among the ancient Romans, not unlike our lord chief justices, or lord-chancellor, or both in one; as being vested with the power of distributing justice among the citizens.

**PRETORIAN GUARDS**, *Prætorie Cohortæ*, in Roman antiquity, were the emperor's guards, who at length were increased to ten thousand; according to some, they had this denomination from their being stationed at a place in the palace called Pretorium: their commander was stiled præfectus prætorii.

**PREVARICATION**, *Prævaricatio*, in the civil law, is where the informer colludes with the defendants, and so makes only a sham prosecution.

**PREVARICATION**, in our laws, is when a man falsely seems to undertake a thing, with intention that he may destroy it; where a lawyer pleads booty, or acts by collusion, &c.

**PREVARICATOR**, *Prævaricator*, at Cambridge, is a master of arts, chosen at a commencement, to make an ingenious satirical speech, reflecting on the misdemeanors of the principal members.

**PREVENTION**, *Præventio*, in the canon-law, &c. the right which a superior person has to claim or transact an affair, prior to an inferior one.

**PRIAPISM**, *πριαπισμος*, in medicine, a continual and painful erection of the penis.

**PRIAPUS**, in medicine, denotes the genital parts in men.

It also denotes, in antiquity, a fabulous deity, revered very much for the extraordinary size of his parts.

**PRICKING**, in the sea language, is to make a point on the plat or chart, near about where the ship then is, or is to be at such a time, in order to find the course they are to steer. See the articles **NAVIGATION** and **SAILING**.

**PRIEST**, *Sacerdos*, a person set apart for the performance of sacrifice, and other offices of religion.

**PRIEST**, *Presbyter*, in the christian church, is a person invested with holy orders; in virtue whereof he has a power to preach, pray, administer the sacrament, &c. Also in the Romish church, to bless, absolve, &c.

**PRIMÆ VIÆ**, among physicians, denotes the whole alimentary duct; including the oesophagus, stomach, and intestines, with their appendages.

**PRIMAGE**, in commerce, a small duty at the water-side, usually about twelve-pence per tun, or six-pence a bale, due to the master and mariners of a ship; to the master for the use of ropes, &c. to discharge the goods; and to the mariners, for the loading or unloading of the vessel.

**PRIMARY-PLANET**, in astronomy, one that revolves round the sun as a center.

**PRIMATE**, *Primas*, in church-polity, an archbishop, who is invested with a jurisdiction over other bishops.

**PRIME**, *Primus*, an appellation given to whatever is first in order, degree, or dignity, among several things of the same or like kind; thus we say, the prime minister, prime cost, &c.

Prime is sometimes used to denote the same with decimal, or the tenth part of an unit. See the article **DECIMAL**.

In weights, it stands for the twenty-fourth part of a grain. See **WEIGHT** and **GRAIN**.

**PRIME Figure**, in geometry, one which cannot be divided into any other figures more simple than itself, as a triangle among planes, and the pyramid among solids. See the article **FIGURE**.

For prime numbers, in arithmetic, see the article **NUMBER**.

**PRIME of the Moon**, is the new moon, when she first appears, which is about three days after the change. See the article **MOON**.

**PRIME VERTICAL**, is that vertical circle which passes through the poles of the meridian, or the east and west points of the horizon; whence dials projected on the plane of this circle, are called prime vertical, or north and south dials. See the articles **VERTICAL**, **DIAL**, &c.

**PRIME**, in the Romish church, is the first of the canonical hours, succeeding to lauds.

**PRIME**, in fencing, is the first chief of the guards. See the article **GUARD**.

**PRIMING**, or **PRIME of a Gun**, is the gunpowder put into the pan or touch-hole of a piece, to give it fire thereby; and this is the last thing done in charging.

**PRIMING**, among painters, signifies the laying on of the first colours.

**PRIMITIVE**, in grammar, is a root or original word in a language, in contradistinction to derivative: thus, *God* is a primitive; *godly*, derivative; and *god-like*, a compound.

**PRIMOGENITURE**, *Primogenitura*, the right of first-born.

**PRIMULA**, the primrose, in botany, a genus of plants, whose flower is monopetalous; the tube is cylindraceous; the length of the cup and the limb is expanded, and divided into five cordated segments: the stamina are five short filaments, placed in the neck of the corolla, and terminated by erect acuminate antheræ: the fruit is an oblong capsule, opening at the top, and filled with roundish seeds.

This genus includes the auricula of Tournefort, and the polyanthus of the gardeners. See the articles **AURICULA** and **POLYANTHUS**.

The common primrose grows almost every where, among fields, woods, and shady places; the flowers,

leaves,

leaves, and roots, are reckoned good in paralytic and arthritic complaints.

**PRIMUM MOBILE**, in the Ptolemaic system of astronomy. See the article **MOBILE**.

**PRINCE**, *Princeps*, in polity, a person invested with the supreme command of a state, independent of any superior.

Prince also denotes a person who is a sovereign in his own territories, yet holds of some other as his superior.

**PRINCE of the Senate**, in old Rome, the person who was called over first in the roll of senators, whenever it was renewed by the censors: he was always of consular and censorian dignity. See the article **SENATE**.

**PRINCE'S-FEATHER**, in botany. See the article **AMARANTHUS**.

**PRINCE'S-METAL**. See **METAL**.

**PRINCIPAL**, *Principalis*, the chief and most necessary part of a thing.

In commerce, principal is the capital of a sum due or lent, so called in opposition to interest.

It also denotes the first fund put by partners into a common stock, by which it is distinguished from the calls or accessions afterwards acquired.

**PRINCIPAL Point**, in perspective, is a point in the perspective plane, upon which a line drawn from the eye, perpendicular to the plane, falls. It is in the intersection of the horizontal and vertical plane, and called the point of sight, and point of the eye.

**PRINCIPAL Ray**, in perspective, that which passes perpendicularly from the spectator's eye to perspective plane.

**PRINCIPLE**, *Principium*, in general, is used for the cause, source, or origin of any thing.

**PRINCIPLE** is also sometimes used in a synonymous sense with axiom or maxim. See the articles **AXIOM** and **MAXIM**.

**PRINOS**, the winter-berry, in botany, a genus of plants, whose flower is monopetalous and rotated, with the limb divided into six plane segments. The fruit is a roundish berry, having six cells, containing solitary, fleshy, obtuse seeds.

**PRINT**, the impression taken from a copper-plate.

**PRINTER**, a person who composes and takes impressions from moveable characters ranged in order, or front-plates engraven, by means of ink, and a press; or from blocks of wood cut in flowers, &c. and taken off in various colours on calicoes, linens, silks, &c.

**PRINTING**, the art of taking impressions from characters or figures, moveable or immovable, on paper, linen, silk, &c. There are three kinds of printing, the one from moveable letters for books; the other from copper-plates for pictures; and the last from blocks, in which the representation of

birds, flowers, &c. are cut for printing calicoes, linens, &c. the first, called common press-printing, the second rolling-press printing, and the last calicoe, &c. printing. The principal difference between the three consists in this, that the first is cast in relievo in distinct pieces, the second engraven in creux, and the third cut in relievo, and generally stamped, by placing the block upon the materials to be printed, and striking upon the back of it.

*Progress of PRINTING.* Who the first inventors of the European method of printing books were, in what city, and what year it was set on foot, are questions long disputed among the learned. In effect, as the Grecians contended for the birth of Homer, so do the German printers for that of printing. Mentz, Haerlem, and Straßburg, are the warmest on this point of honour, and these are left in possession of the question, which is not yet decided: though it must be owned, that Mentz has always had the majority of voices. John Guttemberg, and John Fust, of Mentz; John Mentel, of Straßburg, and L. John Koster, of Haerlem, are the persons to whom this honour is severally ascribed, by their respective country-men; and they have all their advocates among the learned. However, their first essays were made on wooden blocks, after the Chinese manner. The book at Haerlem, the vocabulary called Catholicon, and the pieces in the Bodleian library, and that of Bennet-college, are all performed this way; and the impression appears to have been only given on one side of the leaves; after which the two blank sides were pasted together. But they soon found the inconveniencies of this method, and therefore bethought themselves of an improvement; which was by making single letters distinct from one another; and these being first done in wood, gave room for a second improvement, which was the making them of metal; and, in order to that, forming moulds, matrices, &c. for casting them. See **LETTER**.

From this ingenious contrivance we ought to date the origin of the present art of printing, contradicting from the method practised by the Chinese. And of this, Schoeffer, or Scheffer, first servant, and afterwards partner and son-in-law of Fust, at Mentz, above-mentioned, is pretty generally allowed to be the inventor: so that he may properly be reckoned the first printer; and the Bible, which was printed with moveable letters in 1450, the first printed book; the next was Augustine de civitate Dei; then Tully's Offices, printed about the year 1461. In these books they left the places of the initial letters blank, and gave them to the illuminers, to have them ornamented and painted in gold and azure, in order to render the book more beautiful, and, as some think, to make their books pass for manuscripts. Thus at present, in some curious works, the initial letter at the beginning of a book

a book, or chapter, is sometimes left out, and a space is left for its being afterwards printed with various ornaments from a copper-plate.

Some authors tell us, that Fust carrying a parcel of bibles with him to Paris, and offering them to sale as manuscripts; the French, upon considering the number of books, and their exact conformity to each other, even to a point, and that it was impossible for the best book-writers to be so exact, concluded there was witchcraft in the case, and by their actually indicting him as a conjurer, or threatening to do so, extorted from him the secret: and hence the origin of the popular story of Dr. Faustus.

From Mentz, the art of printing soon spread itself throughout a good part of Europe; Haerlem and Strasburg had it very early; which, as the current of authors represent it, occasioned their pretending to the honour of the invention. From Haerlem it passed to Rome in 1467; and into England in 1468, by means of Thomas Bouchier, archbishop of Canterbury, who sent W. Turner, master of the robes, and W. Caxton, merchant, to Haerlem to learn the art. These privately prevailing with Corseilles, an under-workman, to come over, a press was set up at Oxford, and an edition of Ruffinus on the creed was printed the same year in octavo. From Oxford, Caxton brought it to London about the year 1470, and the same year it was carried to Paris. Hitherto there had been nothing printed but in Latin, and the vulgar tongues; and this first in Roman characters, then in Gothic, and at last in Italic; but in 1480, the Italians cast a set of Greek types, and they have also the honour of the first Hebrew editions which were printed about the same time with the Greek. Towards the end of the sixteenth century, there appeared various editions of books, in Syriac, Arabic, Persian, Armenian, Coptic or Egyptian characters, some to gratify the curiosity of the learned, and others for the use of the Christians of the Levant. Out of Europe, the art of printing has been carried into the three other parts of the world: for Asia, we see impressions of books at Goa, and in the Philippines; at Morocco, for Africa; at Mexico, Lima, Philadelphia, New-York, Boston, &c. for America. The Turks, indeed, rigorously prohibit printing throughout their empire, as imagining that the too frequent communication with books might occasion some change in their religion and government; yet the Jews have several editions of their books printed at Thessalonica, and even at Constantinople.

*Method of PRINTING.* The printing-letters, or types, as they are sometimes called, we have already taken notice of, and have described the method of forming and casting them under the articles *LETTER* and *LETTER-FOUNDERY*.

The workmen employed in the art of printing are of two kinds; compositors, who range and dispose the letters into words, lines, pages, &c. according to the copy delivered them by the author: and pressmen, who apply ink upon the same, and take off the impression. The types being cast, the compositor distributes each kind by itself among the divisions of two wooden frames, an upper and an under one, called cases; each of which is divided into little cells or boxes. Those of the upper case are in number ninety-eight; these are all of the same size, and in them are disposed the capitals, small-capitals, accented letters, figures, &c. the capitals being placed in alphabetical order. In the cells of the lower-case, which are fifty-four, are placed the small letters, with the points, spaces, &c. The boxes are here of different sizes, the largest being for the letters most used; and these boxes are not in alphabetical order, but the cells which contain the letters ofteneft wanted, are nearest the compositor's hand. Each case is placed a little aslope, that the compositor may the more easily reach the upper-boxes. The instrument in which the letters are set is called a composing-stick, (see plate LXXV. fig. 5.) which consists of a long and narrow plate of brass or iron, &c. *cc*, on the right side of which arises a ledge *bb*, which runs the whole length of the plate, and serves to sustain the letters, the sides of which are to rest against it: along this ledge is a row of holes, which serve for introducing the screw *f*, in order to lengthen or shorten the extent of the line, by moving the sliders *e*, *d*, farther from, or nearer to the short ledge at the end *a*. Where marginal notes are required in a work, the two sliding pieces *e*, *d*, are opened to a proper distance from each other; in such a manner as that while the distance between *d* and *c* forms the length of the line in the text, the distance between the two sliding-pieces forms the length of the lines for the notes on the side of the page. Before the compositor proceeds to compose, he puts a rule, or thin slip of brass plate, cut to the length of the line, and of the same height as the letter in the composing-stick, against the ledge, for the letter to bear against. Things thus prepared, the compositor having the copy lying before him, and his stick in his left-hand, his thumb being over the slider *d*; with the right he takes up the letters, spaces, &c. one by one, and places them against the rule, while he supports them with his left thumb by pressing them to the end of the slider *d*; the other hand being constantly employed in setting in more letters: the whole being performed with a degree of expedition and address not easy to be imagined.

A line thus composed, if it end with a word or syllable, and exactly fill the measure, there needs no farther care; otherwise more spaces are to be put in, or else the distances lessened between the several

things, therefore, cannot be sufficiently dried for triture, without exhaling their better parts, or destroying that particular quality for which the simple is valued in medicine, as it happens with many seeds and gums, they are much better in any other form than this. The other requisite in this form, relating to the preservation of things reduced into it, directs not to prescribe materials therein which are volatile, or will any other way change in the open air. The preparations, intentions, &c. of the several powders used in medicine, may be seen under their several heads. See POWDER.

**PULVIS FULMINANS**, among chemists, a powder so called from its smart and loud explosion, when it begins to melt after being placed upon an iron plate over a gentle fire. It is prepared thus: take three ounces of purified nitre, and one ounce of brimstone, and grind them well together in a mortar; then putting a small quantity, as about half a dram, over the fire, in the manner already mentioned, it will make a great explosion. The more philosophical way of accounting for this effect of the pulvis fulminans is, according to Dr. Shaw, by supposing that the acid spirits of the nitre and sulphur being loosened by the heat, rush towards one another, and towards the salt of the tartar, with so great a violence, as by the shock at once to turn the whole into vapour and smoke.

**PUMICE**, in natural history, a slag or cinder of some fossil, originally bearing another form, and only reduced to this state by the action of the fire, though generally ranked by authors among the native stones. It is a lax and spongy matter, frequently of an obscure, striated texture in many parts, and always very cavernous and full of holes; it is hard and harsh to the touch, but much lighter than any other body that comes under the class of stones. It is found in masses of different sizes, and of a perfectly irregular shape, from the bigness of a pigeon's egg to that of a bushel. We have it from many parts of the world, but particularly from about the burning mountains *Ætna*, *Vesuvius*, and *Hecla*, by whose eruptions it is thrown up in vast abundance; and being by its lightness supported in the air, is carried into seas at some distance by the winds, and thence to distant shores. The great use of pumice among the antients, seems to have been as a dentifrice, and at present it is retained in the shops on the same account.

**PUMMEL**. See the article **POMMEL**.

**PUMP**, *Antlia*, in hydraulics, a machine formed on the model of a syringe, for raising water. See the article **SYRINGE**.

The theory of pump-work depends, in a great measure, upon the properties of the inverted syphon: thus, let *ABCDEFG* (plate *LXXVII. fig. 12.*) represent an inverted syphon, *ABCD* a column of air, and *DG* the lower part of the pipe of a pump,

immersed in the water of the well *HI*. Let *P* be the piston of the pump at *E* in its lowest situation, and at *F* in its highest. Now, as both these parts communicate with the water, one by pressing on it, the other by opening into it, they may be looked upon as communicating with one another.

Wherefore, *ABCD* (the column of air) would by its weight or pressure force up a column of water into the pipe *DG* to the height of thirty-two feet, were the air exhausted from the said pipe, and continued to that height; since the weight of a column of air is equal to that of such a column of water of the same base. If, therefore, the piston *P* be thus thrust down to *E*, meeting the water there, and from thence it be raised to *F* with an uniform motion, the water will rise from *E* to follow the piston with a variable motion; the least of which is as  $\sqrt{AC-DE}$ , and the greatest as  $\sqrt{AC-DE} = \sqrt{AB}$ .

If in lifting up the piston, the velocity of the water be less than that of the piston, it will not be able to follow it; but will leave a space between them, which will increase more and more as the velocity of the water becomes less than that of the piston. The consequence of this will be, that a part of the stroke of the piston will be lost; and not only that, but the piston, when the water leaves it, will rise very hard, as having a weight of water upon it, and the air of greater density above than below; whence the equilibrium, which ought to be in pumps, is destroyed, and the balance against the workman.

Now as this can happen even where the diameter of the sucking-pipe is equal to that of the pump-barrel, it must happen much sooner when the sucking-pipe is less than the barrel; because the water rising thro' a less passage, will be longer in filling the pump-barrel, and consequently must quit the piston, and leave the greater void space between. On the contrary, if the least velocity of the water, rising into the pipe, be greater than that of the piston, there will be no void space; and the pump-barrel may be made in proportion as much wider than the sucking-pipe, as the velocity of the water is greater than that of the piston.

Now, that this may be the case, we shall shew by calculation what diameters the barrel and pipe ought to have, compared with the velocity of the water and piston.

Let *A* represent the least altitude of the atmosphere  $AC = 31$  feet of water;  $B = DF$  the highest elevation of the piston above the surface of the water *HI*, which let be 16 feet. And let the greatest velocity of the piston which can well be given to a pump be that of four feet in a second  $= v$ ; and  $V =$  the least velocity of the water that rises in the pipe;  $D =$  the diameter of the barrel; and  $d =$  the diameter of the pipe.

Now here we have  $\sqrt{A} - \sqrt{B} = V =$  the least velocity of water; and the fall which will produce  
9 E that

that velocity is the square of that expression, viz.  $A + B = 2\sqrt{AB}$ , that is,  $31 + 16 = 2\sqrt{31 \times 16} = 2$  feet 6 inches, the height of the fall required. Whereas, by the common way of taking the square of  $\sqrt{A-B}$ , viz.  $A-B$  for the height, we have 15 feet for the fall, which extraordinary error must be of very bad consequence in practice.

Here the velocity  $\sqrt{A} - \sqrt{B} = \sqrt{31} - \sqrt{16} = 5,6 - 4 = 1,6$  per second. The velocity of the water, at the bottom of the pipe  $D$ , is as  $\sqrt{A} = 5,6$ ; that also must be the velocity of the piston at  $D$ , that the water may follow it; whence the piston moving with the same velocity at  $F$ , where the velocity is but 1,6, we have  $5,6 - 1,6 = 4$  feet of void space; therefore 4 parts in 5,6 of such a stroke would be lost or ineffectual. We may here observe, by the way, that since the velocity of the water at  $D$  is 5,6, and the greatest velocity which can be given to the piston (without damaging the machinery) is but 4; therefore a piston, working at the lower end of the pipe or barrel, will always have water more than enough to prevent any void space or loss of labour.

But, since we find so great a void in the pipe at  $F$ , of the same diameter with the piston, it is evident, if we contract all the part below  $F$  into a small pipe at  $FD$ , and let the part  $FG$  remain as it was for the barrel for the piston to play in, as at  $FG$ , that then the water will rise into the barrel  $FG$  with a greater velocity than before, in proportion as the pipe is less; consequently, if the bore of the pipe  $FD$  be to that of the barrel  $FG$ , as the velocity of the piston  $P$ , or the water in the barrel, is to the velocity of the water in the pipe, there will always be a sufficiency of water to prevent a vacuum in the barrel. Which rule in symbols is thus expressed,  $DD:dd::V:v$ ; whence  $D^2v = d^2V$  for a general canon; any three of which quantities being given, the fourth may be found. Thus, for example, suppose  $D$ ,  $v$ , and  $V$ , were given to find  $d$ , we have  $d = \frac{D\sqrt{v}}{\sqrt{V}}$ .

Let the diameter of the barrel  $D = 6$  inches; and suppose the piston gives 20 strokes in a minute, each a two feet stroke, spending as much time in its ascent as descent; then will the motion of the piston be 80 feet per minute, or  $1\frac{1}{3}$  per second; whence,  $v = 1\frac{1}{3}$ . Lastly, to obtain the value of  $V$ , we must fix on the length of the pipe  $FD$ , which let be 16 feet; then the highest elevation of the piston will be 18 feet (if it comes to the bottom of the barrel, as it ought to do); wherefore, a height of water of 18 feet in the pump  $GD$ , acts against the weight or height of 31 feet in the leg  $AC$ . Now, the velocity  $V$  of the water in the pipe  $FD$  being uniform, or constantly the same, we must find what difference of uniform velocities will be generated by

falls from 31 and 18 feet heights. Thus  $\sqrt{16\frac{1}{2}}:32::\sqrt{31}:43$  nearly; and  $\sqrt{16\frac{1}{2}}:32::\sqrt{18}:32\frac{3}{4}$ ; whence the difference of these uniform velocities will be  $43 - 32\frac{3}{4} = 10\frac{1}{4} = 10$  feet three inches per second; therefore  $V = 10\frac{1}{4}$ . Wherefore  $\frac{D\sqrt{v}}{\sqrt{V}} =$

$d = 2\frac{1}{10}$  inches of the diameter of the pipe  $FD$ .

The reason why we make no use of the expression  $\sqrt{AB} - \sqrt{DF}$  in this case, is, because this gives only the difference of the instantaneous velocities, or the least velocity with which the water at  $F$  can begin its motion upwards; whereas we here want to find what the constant and uniform motion of the water will be, or how much it will supply every second uniformly, which is done by the method above. For, since a fall of  $16\frac{1}{2}$  gives an uniform velocity of 32 feet per second, a fall of 31 feet will give 43; thus a fall of 18 feet will give  $32\frac{3}{4}$ , and their difference must be that of the water at  $F$ .

If we know the velocity of the piston  $v$ , the diameter of the barrel  $D$ , and the diameter of the pipe  $d$ , we shall find the velocity of the water in the pipe  $V$ ,  $= \frac{vDD}{dd}$ ; or thus in words, multiply the square of the diameter of the barrel by the velocity of the piston; divide the product by the square of the diameter of the pipe, the quotient will be the velocity sought from the water in the pipe. This velocity, when found, must be taken from 43, the remainder  $43 - V$ , will be the uniform velocity produced by a fall from the highest situation of the piston to the lowest surface of the water in the well, and which is found by saying, as  $32:\sqrt{16\frac{1}{2}}::43-V:\sqrt{DF}$ ; whence  $DF$ , the highest elevation of the piston, will be known.

When we know  $D$ ,  $V$ , and  $d$ , we find  $v$  the velocity of the piston by this theorem  $\frac{Vdd}{DD} = v$ ; that is, in words, multiply the square of the diameter of the pipe by the velocity of the water in it, and divide the product by the square of the diameter of the barrel, the quotient is the velocity of the piston required.

Having given the velocity of the water in the pipe  $V$ , the diameter of the pipe  $d$ , the velocity of the piston  $v$ , to find the diameter of the barrel  $D$ , we have this theorem  $D = \sqrt{\frac{Vdd}{v}}$ ; that is, multiply the square of the diameter of the pipe by the velocity of its water, and divide that product by the velocity of the piston; the square root of the quotient is the diameter of the barrel sought.

PUN, or PUNN, a conceit arising from the use of two words that agree in sound, but differ in the sense. Aristotle describes two or three kinds of puns among the beauties of good writing, and produces instances of them out of some of the greatest authors.

authors in the Greek tongue. Cicero has sprinkled several of his works with puns; and in his book, where he lays down the rules of oratory, quotes abundance of sayings, which he calls pieces of wit, that upon examination prove perfect puns.

**PUNCH**, an instrument of iron or steel, used in several arts, for the piercing or stamping holes in plates of metals, &c. being so contrived as not only to perforate, but to cut out and take away the piece.

**PUNCHEON**, **PUNCHIN**, or **PUNCHION**, a little block or piece of steel, on one end whereof is some figure, letter or mark, engraven either in creux or relievo, impressions whereof are taken on metal, or some other matter, by striking it with a hammer on the end not engraved. There are various kinds of these puncheons used in the mechanical arts; such for instance are those of the goldsmiths, cutlers, pewterers, &c.

**PUNCHEON**, is also used for several iron-tools of various sizes and figures, used by the engravers in creux on metals. Seal-gravers particularly use a great number for the several pieces of arms, &c. to be engraven, and many stamp the whole seal from a single puncheon.

**PUNCHEON**, is also a common name for all those iron instruments used by stone-cutters, sculptors, black-smiths, &c. for the cutting, incising, or piercing their several matters.

**PUNCHEON**, in carpentry, is a piece of timber placed upright between two posts, whose bearing is too great, serving, together with them, to sustain some large weights.

**PUNCHEON**, is also used for the arbor, or principal part of a machine, whereon it turns vertically, as that of a crane, &c.

**PUNCHEON**, is also a measure for liquids, containing an hogshead and one third, or eighty-four gallons.

**PUNCTATED HYPERBOLA**, an hyperbola whose oval conjugate is infinitely small, i. e. a point.

**PUNCTUATION**, in grammar, the art of pointing or of dividing a discourse into periods, by points, expressing the pauses to be made in the reading thereof. See the article **POINT**.

**PUNCTUM**, in geometry, &c. See the article **POINT**.

**PUNCTUM SALIENS**, in anatomy, the first rudiments of the heart in the formation of the fœtus, where a throbbing motion is perceived. This is said to be easily observed with a microscope in a brood egg, wherein, after conception, we see a little speck or cloud, in the middle whereof is a spot that appears to beat or leap a considerable time before the fœtus is formed for hatching. See the article **FOETUS**.

**PUNCTURE**, in surgery, any wound made by a sharp pointed instrument.

**PUNICA**, the **POMEGRANATE-TREE**, in botany. See the article **POMEGRANATE**.

**PUNISHMENT**, in law, the penalty which a person incurs on the breach or transgression of any law.

**PUNITORY INTEREST**, in the civil law, such interest of money as is due for the delay of payment, breach of promise, &c.

**PUPIL**, *Pupillus*, in the civil law, a boy or girl not yet arrived at the age of puberty, i. e. the boy under fourteen, years the girl under twelve.

**PUPIL** is also used in universities, &c. for a youth under the education or discipline of any person.

**PUPIL**, *Pupilla*, in anatomy, a little aperture in the middle of the uvea and iris of the eye, through which the rays of light pass to the crystalline, in order to be painted on the retina, and cause vision.

The structure of the uvea and iris, is such as that by their aperture the pupil is contractible and dilatible at pleasure, so as to accommodate itself to objects, and to admit more or fewer rays; as the object, being either more vivid and near, or more obscure and remote, requires more or less light: it being a constant law, that the more luminous the object is, the smaller the pupil; and again, the nearer the object, the smaller the pupil; and *vice versa*. This alteration of the pupil is effected by certain muscular fibres on the outside of the uvea, which arrive from the nerves detached hither from the sclerotica: some others attribute the motions of the pupil to the ligamentum ciliare; and others think that both this and the fibres of the uvea concur herein.

There is a disease of the eyes called a contraction of the pupil, wherein there is such a total or close contraction of that part, that it will not transmit light enough to the bottom of the eye, to enable the patient to see objects distinct; sometimes this disorder is from infancy, and sometimes it arises from an intense inflammation of the eye. The cure of this is extremely difficult; but Mr. Cheselden has invented a method by which he has often proved very successful in his attempts to relieve it. The method is this: the eye-lids being held open by a speculum oculi, he takes a narrow single edged scalpel, or needle, almost like that used in couching for the cataract, and passing it through the sclerotica, as in couching, he afterwards thrusts it forward through the uvea, or iris, and in extracting cuts it open through the iris. See the article **COUCHING**.

**PURCHASE**, in law, the buying or acquiring of lands, &c. with money, by deed or agreement, and not by descent or right of inheritance.

**PURCHASE**, in the sea-language, is the same as draw in: thus when they say the capstan purchases a-pace, they only mean it draws in the cable a-pace.

**PURE**,

PURE, something free from any admixture of foreign or heterogeneous matters: thus we say pure fire, &c. See the article FIRE, &c.

PURE HYPERBOLA, in conics, is an hyperbola without any oval, nodes, spike, or conjugate point.

PURFLEW, a term in heraldry, expressing ermins, peans, or any of the furs, when they compose a bordure round a coat of arms: thus they say, he beareth gules a bordure, purflew, vary: meaning that the bordure is vary.

PURGATION, the art of purging, scouring, or purifying a thing, by separating or carrying off any impurities found therein.

PURGATIVE, or PURGING MEDICINES, a medicament which evacuates the impurities of the body by stool, called also cathartics.

We have had attempts of adjusting the doses of purgative medicines scientifically. Dr. Cockburn endeavoured at the solution of this problem, but, it is said upon wrong principles. Dr. Balguy, in the Medical Essays of Edinburgh, has also given us an essay on this subject. He assumes, that part of the medicines is spent on the first passages, where it acts as a stimulus; and that the other part is carried into the blood, and has its effects there by thinning and rarifying it. This being premised, 1. If the medicine acts only in the first passages, the dose will be as the size of the person into the constitution. 2. If the whole medicine passes into the blood, the dose will be as the size into the square of the constitution; and, therefore, 3. You are to dose so much of the medicine as is spent on the stomach and intestines directly as the constitution, and so much as is carried into the blood as the square of the constitution; and the sum into the persons size, is the quantity required. The same rules hold in vomits. How far in either case the practice of physic may be thereby improved, we leave to the judgment of the learned. The solution of the problem supposes a great postulatum, no less than the art of measuring a person's constitution.

PURGATORY, a place in which the just, who depart out of this life, are supposed to expiate certain offences which do not merit eternal damnation.

Broughton has endeavoured to prove, that this notion has been held by Pagans, Jews, and Mahometans, as well as Christians.

The doctrine of purgatory is a very lucrative article to the clergy of the Romish church, who are very liberally paid for masses and prayers for the souls of the deceased. We are told by some of their doctors, that purgatory is a subterraneous place, situated over the hell of the damned, where such souls as have not yet made satisfaction to divine justice for their sins, are purged by fire, after a wonderful and incomprehensible manner: and here they are purified from those dregs which hinder them

from entering into their eternal country, as the catechism of the council of Trent expresses it.

PURGE, in medicine, the same with cathartic. See the article CATHARTIC.

PURIFICATION, in matters of religion, a ceremony which consists in cleansing any thing from a supposed pollution or defilement.

The Pagans, before they sacrificed, usually bathed or washed themselves in water, and they were particularly careful to wash their hands, because with these they were to touch the victims consecrated to the gods. It was also customary to wash the vessel with which they made their libations. The Mahometans use purifications as previous to the duty of prayer; these also are of two kinds, either bathing, or only washing the face, hands and feet. The first is requested only in extraordinary cases, as after having lain with a woman, touched a dead body, &c. But lest so necessary a preparation for their devotions should be omitted, either where water cannot be had, or when it may be of prejudice to a person's health, they are allowed in such cases to make use of fine sand, or dust instead of it; and then they perform this duty by clapping their open hands on the sand, and passing them over the parts, in the same manner as if they were dipped in water.

There were also many legal purifications among the Hebrews. When a woman was brought to bed of a male child, she was esteemed impure for forty days; and when of a female, for sixty; at the end of which time she carried a lamb to the door of the temple, to be offered for a burnt-offering, and a young pigeon or turtle for a sin-offering, and by this ceremony she was cleansed or purified. For other purifications of the Jews, see the article IMPURITY.

Among the Romanists, the holy water is used by way of purification.

PURIFICATION of the blessed Virgin, a festival of the christian church, observed on the second of February, in memory of the purification of Christ in the temple, and his mother's submitting to the Jewish law of purification after the birth of a male child.

PURIFICATION, in chemistry, the act of purifying or refining natural bodies by separating the faeces and impurities from them. For the method of purifying metals, see the article REFINING, &c.

For the purification of semi-metals, see the articles ANTIMONY, SULPHUR, &c.

PURIM, or the Feast of Lots, a solemn festival of the Jews, instituted in memory of the deliverance they received from Haman's wicked attempt to destroy them by means, of Mordecai and Esther.

PURITAN, a name formerly given in derision to the dissenters from the church of England, on account of their professing to follow the pure word of God, in opposition to all traditions and human constitutions.

constitutions. See the articles INDEPENDENTS, PRESBYTERIANS, &c.

**PURLINS**, in building, those pieces of timber that lie across the rafters on the inside, to keep them from sinking in the middle of their length.

**PURLUE**, or **PURLIEU**, signifies all that ground near any forest, which being made forest by king Henry II. Richard I. and king John, was afterwards by perambulations and grants of Henry III. severed again from the same, and made purlieu; that is to say, pure and free from the laws of the forest.

The owners of grounds within purlieus, may convert pasture into arable, &c. as also inclose them with any kind of inclosures, or erect edifices upon them, and may dispose of the same as if they had never belonged to the forest: hence if the wild beasts chance to wander out of the forest into the purlieu, the king has still a property in them, against every man except the owner of the ground in which they are who had a special property in them *ratione soli*; yet so far as he may take them by hunting with his greyhounds or dogs, without any fore-stalling or fore-setting them in their course again towards the forest.

**PURLUE-MAN**, or **PURLIEU-MAN**, a person who has ground within the purlieu, and is qualified to hunt within the same though under certain restrictions.

**PURPLE**, a colour composed of a mixture of red and blue.

**PURPLE FEVER**, the same with miliary fever. See **MILIARY FEVER**.

**PURPURA**, in natural history, a genus of simple shells, having no hinge, formed of one contiguous piece, and covered from the top to the bottom with spines, tubercles, and umbos; the mouth is small, and approaches to a round figure: the clavicle is short, but the other extremity is usually pretended to a considerable length.

**PURPURE**, **POURPRE**, or **PURPLE**, in heraldry, according to some, is one of the five colours of armories, compounded of gules and azure, bordering on violet, and, according to others, of a great deal of red and a little black. But it was excluded by the ancient heralds as only an imperfect colour. In the coats of noblemen it is called amethyst; and in those of princes, mercury. It is represented in engraving, by diagonal lines drawn from the sinister chief to the dexter base point.

**PURREL**, a list ordained by act of parliament to be made at the end of kerseys, to prevent deceit in diminishing their length.

**PURSE**, a manner of accounting, or a species of money of account, much used in the Levant.

**PURSER**, an officer aboard a man of war, who receives her victuals from the victualler, sees that it be well stowed, and keeps an account of what he every day delivers to the steward. He also keeps a

list of the ship's company, and sets down exactly the day of each man's admission, in order to regulate the quantity of provisions to be delivered out, and that the paymaster or treasurer of the navy may issue out the disbursements, and pay off the men, according to his book.

**PURSIVENESS**, among farriers, is a disorder in horses, otherwise called broken wind, in which the horse makes a hissing whistling sound in his throat, and has a greater heaving in the flanks than in common colds.

For the cure of this disorder, Dr. Bracken advises, that the horse should have good nourishment, much corn, but little hay; and that every other day the water given him be impregnated with half an ounce of saltpetre, and two drams of sal armoniac.

**PURSLAIN**, *Portulaca*, in botany. See the article **PORTULACA**.

**PURULENT**, in medicine, something mixed with, or partaking of, pus or matter.

**PUS**, in medicine, a white or yellowish putrid matter, formed of corrupted blood, and contained in a wound or ulcer.

**PUSTULE**, a pimple, or small eruption on the skin full of pus; such are the pustules of the small pox and French pox. See the article **Pox**.

**PUTLOGS**, or **PUTLOCKS**, in building, are short pieces of timber about seven feet long, used in building scaffolds. They lie at right angles to the wall, with one of their ends resting upon it, and the other upon the poles which lie parallel to the side of the wall of the building.

**PUTREFACTION**, a kind of slow corruption produced by heat and some moist fluid, particularly the air and water; which, penetrating the pores, dissolves and sets at liberty some of the more subtle parts, particularly the salts and oils, and thus loosens the compages, and changes the texture of bodies.

**PUTRID**, something rotten, or putrified.

**PUTTY**, the same with spodium. See the article **SPODIUM**.

**PUTTY**, in its popular sense, is a kind of paste compounded of whiting and linseed oil, beaten together to the consistence of a thick dough.

It is used by glaziers for the fastening in the squares of glass in sash-windows, and by painters for stopping up the crevices and clefts in timber and wainscots, &c.

**PUTTY** sometimes also denotes the powder of calcined tin, used in polishing and giving the last gloss to works of iron and steel.

**PYCNOSTYLE**, in the antient architecture, is a building where the columns stand very close to each other; only one diameter and a half of the column being allowed for the intercolumniations.

According to Mr. Evelyn, the pycnostyle chiefly belonged to the Composite order, and was used in the most magnificent buildings; as at present in the peristyle

peristyle at St. Peter's at Rome, which consists of near three hundred columns; and in such as yet remain of the antients, among the late discovered ruins of Palmyra.

**PYCNOTICS**, the same with **INCRASSANTS**. See the article **INCRASSATING**.

**PYGME**, the same with **CUBIT**. See the article **CUBIT**.

**PYGMY**, a person not exceeding a cubit in height.

This appellation is given by the antients to a fabulous nation said to have inhabited Thrace; who brought forth young at five years of age, and were old at eight; these were famous for the bloody war they waged with the cranes.

**PYLORUS**, in anatomy, the right or lower orifice of the stomach, which is connected with and opens into the intestines. See the articles **STOMACH** and **INTESTINES**.

**PYONY**, or **PIONY**. See **PIONY**.

**PYRACANTHA**, in botany, a species of *me-spilus*; this is an ever-green plant; it grows naturally in the hedges in the south of France and Italy: the branches are slender, covered with a dark brown bark, and armed with a few long thorns: the leaves are oval, of a lucid green, smooth, and slightly indented on their edges; the flowers are rosaceous, and come from the side of the branches in large umbels, and are of a dirty white colour; they are succeeded by roundish umbilicated berries, which ripen in winter, and are of a fiery red colour, which being intermixed with the green leaves, make a fine appearance at that season of the year. This plant is either propagated by seeds or layers, and with us is generally planted against walls or buildings, as the stalk and branches are too slender and weak to stand without support.

**PYRAMID**, *ωυραμυς*, in geometry, a solid standing on a triangular, square, or polygonal basis, and terminating in a point at the top; or, according to Euclid, it is a solid figure, consisting of several triangles, whose bases are all in the same plane and have one common vertex.

Hence the superficies of a given pyramid is easily found by measuring these triangles separately; for their sum added to the area of the base, is the surface of the pyramid required.

It is no less easy to find the solid content of a given pyramid; for the area of the base being found, let it be multiplied by the third part of the height of the pyramid, or the third part of the base by the height, and the product will give the solid content, as is demonstrated by Euclid, lib. 12. prop. 7.

If the solid content of a frustum of a pyramid is required, first let the solid content of the whole pyramid be found; from which subtract the solid content of the part that is wanting, and the solid content of the frustum, or broken pyramid, will remain. See **FRUSTUM**.

**PYRAMID**, in architecture, a solid massive building, which from a square, triangle, or other base, rises diminishing to a vertex or point.

Pyramids are sometimes used to preserve the memory of singular events; and sometimes to transmit to posterity the glory and magnificence of princes. But as they are esteemed a symbol of immortality, they are most commonly used as funeral monuments. Such is that of Cestius at Rome, and those other celebrated ones of Egypt, as famous for the enormity of their size, as their antiquity. These are situated on the west side of the Nile almost opposite to Grand Cairo; the base of the largest covers more than ten acres of ground, and is, according to some, near seven hundred feet high, though others make it six hundred, and some but little more than five hundred. The pyramid is said to have been, among the Egyptians, a symbol of human life; the beginning of which is represented by the base, and the end, by the apex; on which account it was that they used to erect them over sepulchres.

**PYRAMIDAL**, something relating to a pyramid. See the preceding article.

**PYRAMIDAL NUMBERS**. See **NUMBER**.

**PYRAMIDALIA CORPORA**, in anatomy, the two protuberances of the medulla oblongata. The spermatic vessels are also by some authors thus termed.

**PYRAMIDALIS**, in anatomy, a small muscle in the abdomen lying in the lower part of the rectus. It has its name from its figure, and its origin from the margin of the os pubis, with a broad fleshy head, whence it grows gradually narrower, till it ends in a small round tendon in the linea alba, sometimes almost at the navel. This muscle is sometimes single, sometimes it has its fellow, and in some subjects they are both wanting.

Pyramidalis is also the name of one of the dilatores, or muscles which serve to turn up the nose. This muscle rises at the foot of the nose, and is usually contiguous with the frontalis. It descends along the side of the nose, where it is by degrees a little expanded. It is inserted into the alæ of the nose, and often sends down its fibres as far as the upper lip.

**PYRAMIDOID**, the same with the parabolic spindle.

**PYRENOIDES PROCESSUS**, in anatomy, a process of the second vertebra of the neck, called also odontoides, and densiformis.

**PYRETHRUM**, in the materia medica, the root of a species of the bupthalmum, called, among us, pellitory of Spain. See the article **BUPHTHALMUM**.

**PYRFORMIS**, in anatomy, a muscle of the thigh, receiving its name from its figure, which resembles that of a pear. It rises thick from the lower part of the os sacrum, where it is joined to the ileum; from thence it runs transversely towards the

the joint of the hip, and terminates in a short tendon, which is inserted in the middle of the internal labium of the great trochanter, by two or three branches.

**PYRITES**, in natural history, a name used by Dr. Hill for a class of compound inflammable metallic bodies found in detached masses, but of no determinately angular figure. This class the Dr. divides into two orders, the first of which, being those pyritæ of a plain and simple internal structure, comprehends two genera: the first genus, termed pyriplaces, are those pyritæ of a simple internal structure, and covered with an investient coat or crust; the second genus, termed gymnopyres, are those pyritæ of a simple internal structure, and not covered with a crust; the second order, being those pyritæ of a regularly striated internal structure also, comprehends two genera, the first termed pyritricha are those pyritæ of a simply striated texture; the second genus, called pyritrichiphylla, are those pyritæ whose striæ terminate in foliaceous ends.

This fossile is recommended by some authors as an emmenagogue, but it is scarce ever prescribed with this intention; the common green vitriol, or copperas of the shops, is made from it; and an acid somewhat different from that of pure vitriol may be drawn off from it by the retort, after it has been exposed to the air till it moulders away: this is of great use in mineralogy, and is a solvent for several fossils that none of the other acids will touch.

**PYROLA**, winter-green, in botany, a genus of plants, whose flower cup is small, persistent, and cut into five parts; the corolla consists of five roundish concave patent petals; the stamina are ten subulated filaments, terminating with large nodding antheræ with two rising horns. The fruit is a roundish, depressed, pentagonal capsule, with five cells open at the angles, which are filled with many chaffy seeds.

The greater round-leaved pyrola grows naturally in the north of England, on mountainous and woody places, and flowers in June and July: it is reckoned to be astringent and vulnerary, and proper to stop internal bleedings being taken in the manner of tea.

**PYROTECHNY**, *πυροτεχνία*, the art of fire, or a science which teaches the management and application of fire, in several operations. Pyrotechny is of two kinds, military and chemical: military pyrotechny is the doctrine of artificial fire-works and fire-arms, teaching the structure and use of those used in war, the attacking of fortifications, &c. as gun-powder, cannons, bombs, granadoes, carcasses, mines, fuses, &c. and those made for amusement's sake, as rockets, stars, serpents, &c. See the articles **GUN-POWDER**, **CANNON**, &c.

Chemical pyrotechny is the art of managing and applying fire in distillations, calcinations, and other operations of chemistry.

**PYROTICS**, *πυροπικα*, in medicine, caustics, or remedies, either actually or potentially hot; and which accordingly will burn the flesh, and raise an eschar. See the article **CAUSTICS**.

**PYRRHICHA**, *πυρρική*, in antiquity, a kind of exercise on horseback, or a feigned combat, for the exercise of the cavalry.

**PYRRHICHIUS**, in the Greek and Latin poetry, a foot consisting of two syllables, both short, as *Deus*. See **FOOT**.

**PYRRHONIANS**, **PYRRHONEANS**, or **PYRRHONISTS**, a sect of antient philosophers, so called from Pyrrho, a native of Elis, in Peloponnesus. The opinions of these philosophers, who were also called sceptics, terminated in the incomprehensibility of all things, in which they found reason both for affirming and denying; accordingly they seemed, during their whole lives, to be in search of truth, without ever acknowledging that they found it: hence the art of disputing upon all things, without ever going farther than suspending our judgments, is called pyrrhonism.

Pyrrho maintained, that life and death were equally indifferent; and he is charged with teaching, that honour and infamy, the justice and injustice of actions, depended solely on human laws and customs; and, in a word, that there is nothing in itself honest or dishonest, just or unjust: an abominable doctrine, that opens the way to all manner of crimes.

**PYRUS**, the pear-tree, in botany. See the article **PEAR**.

**PYTHAGOREANS**, a sect of antient philosophers, so denominated from their being the followers of Pythagoras of Samos, who lived in the reign of Tarquin, the last king of the Romans, in the year of Rome 220; or, according to Livy, in the reign of Servius Tullius, in the year of the world 3472.

Pythagoras, from his extraordinary desire of knowledge, travelled in order to enrich his mind with the learning of the several countries through which he passed. He was the first that took the name of philosopher, that is, a lover of wisdom, which implied, that he did not ascribe the possession of wisdom to himself, but only the desire of possessing it.

His maxims of morality were admirable; for he was for having the study of philosophy solely tend to elevate man to a resemblance of the Deity. He believed that God is a soul diffused through all nature, and that from him human souls are derived; that they are immortal, and that men need only take pains to purge themselves of their vices, in order to be united to the Deity. He made unity the principle of all things; and believed, that between God and man there are various orders of spiritual beings, who are the ministers of the supreme being. He condemned all images of the Deity, and would have

have him worshipped with as few ceremonies as possible. His disciples brought all their goods into a common stock, contemned the pleasures of sense, abstained from swearing, eat nothing that had life, and believed in the doctrine of a metempsychosis. See the article *METEMPSYCHOSIS*.

Pythagoras made his scholars undergo a severe noviciate of silence for at least two years; and it is said, that where he discerned too great an itch for talking, he extended it to five: his disciples were therefore divided into two classes, of which the first were simple hearers, and the last such as were allowed to propose their difficulties, and learn the reasons of all that was taught there.

The Pythagoreans, it is said, on their rising from bed, roused the mind with the sound of the lyre, in order to make them more fit for the actions of the day; and at night resumed the lyre, in order to prepare themselves for sleep, by calming all their tumultuous thoughts.

The figurative manner in which he gave his instructions, was borrowed from the Hebrews, Egyptians, and other orientals. Some think he derived his philosophy from the books of Moses, and that he conversed with Ezekiel and Daniel at Babylon; but this is mere conjecture.

Some authors say, that he left nothing in writing; but Laërtius and others attribute several treatises to him. His golden verses, attributed by some to one of his disciples, are allowed to be an exact copy of the sentiments of that divine philosopher, from whose school proceeded the greatest philosophers and legislators.

*PYTHIA*, in antiquity, the priestess of Apollo at Delphi, by whom he delivered oracles: she was thus called from the god himself, who was denominated Apollo Pythios, from his slaying the serpent Python.

This priestess was to be a pure virgin; she sat on the lid of a brazen vessel, mounted on a tripod or three-legged stool; and thence, after a violent enthusiasm, delivered her oracles in a few ambiguous and obscure verses, or in a short sentence in prose. See the article *ORACLE*.

*PYTHIAN GAMES*, in antiquity, solemn games celebrated near Delphi, in honour of Apollo, and in remembrance of his having killed the serpent Python.

These were held every two years, about the month Elaphebolion, which answered to our February. The celebration of these games was attended with the Pythian song, in which was celebrated the fight of Apollo and the serpent. The victors were crowned with branches of laurel; though, at the first institution, the crown was of beech-leaves. See *GAMES*.

*PYXIDIUM*, cup-moss, in botany, a genus of mosses, consisting of a firm, tough, and flexile matter, formed into the shape of hollowed cups, or drinking glasses, with longer or shorter stems.

*PYXIS NAUTICA*, the seaman's compass. See *COMPASS*.

*PYXIS*, in anatomy, the acetabulum, or cavity of the hip-bone. See the articles *ACETABULUM* and *FEMUR*.

MDCCLXVI.

# A GENERAL DICTIONARY OF ARTS and SCIENCES.

Q.

QUA

**Q**, The sixteenth letter, and twelfth consonant of our alphabet; but is not to be found either in the Greek, old Latin, or Saxon alphabets: and indeed some would entirely exclude it, pretending that *k* ought to be used wherever this occurs: however, as it is formed in the voice in a different manner, it is undoubtedly a distinct letter; for in expressing this sound the cheeks are contracted, and the lips, particularly the under one, are put into a canular form, for the passage of the breath.

The *q* is never sounded alone, but in conjunction with *u*, as in *quality*, *question*, *quite*, *quote*, &c. and never ends any English word.

As a numeral, *Q* stands for 500; and with a dash over it, thus *Q̄*, for 500,000.

**QUACK**, among physicians, the same with empiric. See **EMPIRIC**.

**QUADRA**, in building, any square bordure, or frame, encompassing a basso relievo, pannel, painting, or other work: it is also used, but erroneously, for a frame or bordure, of any other form, as round, oval, or the like.

**QUADRAGESIMA**, a denomination given to Lent, from its consisting of forty days. See the article **LENT**.

QUA

Hence, also, the first Sunday of Lent is called *Quadragesima-Sunday*, and the three preceding Sundays, *Quinquagesima*, *Sexagesima*, and *Septuagesima*.

**QUADRANGLE**, in geometry, the same with a quadrilateral figure, or one consisting of four sides and four angles. See **QUADRILATERAL**.

**QUADRANS**, the quarter or fourth part of any thing, particularly the *as*, or pound. See the article *As*.

**QUADRANT**, *Quadrans*, in geometry, an arch of a circle, containing 90°; or the fourth part of the entire periphery. See the articles **CIRCLE** and **DEGREE**.

Sometimes also the space, or area, included between this arch and two radii drawn from the center to each extremity thereof, is called a quadrant, or, more properly, a quadrantal space, as being a quarter of an entire circle.

**QUADRANT**, also denotes a mathematical instrument, of great use in astronomy and navigation, for taking the altitudes of the sun and stars, as also for taking angles in surveying, &c.

This instrument is variously contrived, and furnished with different apparatus, according to the various uses it is intended for; but they all have this

in common, that they consist of a quarter of a circle, whose limb is divided into  $90^\circ$ . Some have a plummet suspended from the center, and are furnished with sights to look through.

The principal and most useful quadrants are the common surveying quadrant, astronomical quadrant, Adams's quadrant, Cole's quadrant, Davis's quadrant, Gunter's quadrant, Hadley's quadrant, horodictical quadrant, Sutton's or Collins's quadrant, and the fenical quadrant, &c.

**Gunter's QUADRANT**, so called from its inventor Edmund Gunter, is represented in plate LXXVII. fig. 13; and besides the apparatus of other quadrants, has a stereographical projection of the sphere on the plane of the equinoctial. It has also a calendar of the months, next to the divisions of the limb.

**Use of Gunter's quadrant.** 1. To find the sun's meridian altitude for any given day, or the day of the month for any given meridian altitude. Lay the thread to the day of the month in the scale next the limb; and the degree it cuts in the limb, is the sun's meridian altitude. Thus the thread, being laid on the 15th of May, cuts  $59^\circ 30'$ , the altitude sought; and contrarily the thread, being set to the meridian altitude, shews the day of the month. 2. To find the hour of the day. Having put the bead, which slides on the thread, to the sun's place in the ecliptic, observe the sun's altitude by the quadrant; then, if the thread be laid over the same in the limb, the bead will fall upon the hour required. Thus suppose on the 10th of April, the sun being then in the beginning of Taurus, I observe the sun's altitude by the quadrant to be  $36^\circ$ ; I place the bead to the beginning of Taurus in the ecliptic, and lay the thread over  $36^\circ$  of the limb; and find the bead to fall on the hour-line marked 3 and 9; accordingly the hour is either 9 in the morning, or 3 in the afternoon. Again, laying the bead on the hour given, having first rectified, or put it to the sun's place, the degree cut by the thread on the limb gives the altitude. Note, the bead may be rectified otherwise, by bringing the thread to the day of the month, and the bead to the hour-line of 12. 3. To find the sun's declination from his place given, and contrariwise. Set the bead to the sun's place in the ecliptic, move the thread to the line of declination ET, and the bead will cut the degree of declination required. Contrarily, the bead being adjusted to a given declination, and the thread moved to the ecliptic, the bead will cut the sun's place. 4. The sun's place being given, to find his right ascension, or contrarily. Lay the thread on the sun's place in the ecliptic, and the degree it cuts on the limb is the right ascension sought. Contrarily, laying the thread on the right ascension, it cuts the sun's place in the ecliptic. 5. The sun's altitude being given, to find his azimuth, and contrariwise. Rectify the bead for the time, as in the

second article, and observe the sun's altitude; bring the thread to the complement of that altitude; thus the bead will give the azimuth sought, among the azimuth lines. 6. To find the hour of the night from some of the five stars laid down on the quadrant. 1. Put the bead to the star you would observe, and find how many hours it is off the meridian, by article 2. Then, from the right ascension of the star subtract the sun's right ascension converted into hours, and mark the difference; which difference, added to the observed hour of the star from the meridian, shews how many hours the sun is gone from the meridian, which is the hour of the night. Suppose on the 15th of May the sun is in the 4th degree of gemini, I set the bead to arcturus; and, observing his altitude, find him to be in the West about  $52^\circ$  high, and the bead to fall on the hour-line of 2 in the afternoon; then will the hour be 11 hours 50 min. past noon, or 10 min. short of midnight: for  $62^\circ$ , the sun's right ascension, converted into time, make 4 hours 8 min. which subtracted from 13 hours 58 min. the right ascension of arcturus, the remainder will be 9 hours 50 min. which added to 2 hours, the observed distance of arcturus from the meridian, shews the hour of the night to be 11 hours 50 minutes.

**Hadley's QUADRANT**, (plate LXXVII. fig. 14.) so called from its inventor J. Hadley, Esq; consists of the following particulars: 1. An octant, or  $\frac{1}{8}$  part of a circle, ABC. 2. An index D. 3. The speculum E. 4. Two horizontal glasses, F, G. 5. Two screens, K, K. 6. Two sight-vanes, H, I.

The octant consists of two radii, AB, AC, which are strengthened by the braces LM, and the arch BC; which though containing only  $45^\circ$ , is nevertheless, divided into 90 primary divisions, each of which stands for degrees, and are numbered, 0, 10, 20, 30, &c. to 90; beginning at each end of the arch for the convenience of numbering both ways, either for altitudes or zenith-distances: again each degree is subdivided into minutes.

The index D, is a flat bar, moveable round the center of the instrument; and that part of it which slides over the graduated arch, BC, is open in the middle, with Vernier's scale on the lower part of it; and underneath is a screw, serving to fasten the index against any division.

The speculum E, is a piece of flat glass, quicksilvered on one side, set in a brass-box, and placed perpendicular to the plane of the instrument, the middle part of the former coinciding with the center of the latter. And, because the speculum is fixed to the index, the position of it will be altered by the moving of the index along the arch. The rays of an observed object are received on the speculum, and from thence reflected on one of the horizon-glasses, F, G; which are two small pieces of looking-glass placed on one of the limbs, their faces being turned obliquely to the speculum, from whence

whence they revive the reflected rays of observed objects. This glass, F, has only its lower part quicksilvered, and set in brass-work; the upper part being left transparent to view the horizon. The glass G has in its middle a transparent slit, through which the horizon is to be seen. And because the warping of the wood-work, and other accidents, may distend them from their true situation, there are three screws passing through their feet, whereby they may be easily replaced.

The screens are two pieces of coloured glass, set in two square brass-frames K, K, which serve as screens to take of the glare of the sun's rays, which would be otherwise too strong for the eye; the one is tinged much deeper than the other, and, as both of them move on the same center, they may be both or either of them used: in the situation they appear in the figure, they serve for the horizon-glass F; but, when they are wanted for the horizon-glass G, they must be taken from their present situation, and placed on the quadrant above G.

The sight-vanes are two pins, H and I, standing at right angles to the plane of the instrument; that at H has one hole in it, opposite to the transparent slit in the horizon-glass G; the other, at I, has two holes in it, the one opposite to the middle of the transparent part of the horizon-glass F, the other rather lower than the quicksilvered part: this vane has a piece of brass on the back of it, which moves round a center, and serves to cover either of the holes.

There are two sorts of observations to be made with this instrument; the one, when the back of the observer is turned towards the object, and therefore called the back-observation; the other, when the face of the observer is turned towards the object, which is called the fore-observation.

To rectify the instrument for the fore-observation: slacken the screw in the middle of the handle behind the glass F; bring the index close to the button *b*; hold the instrument in a vertical position, with the arch downwards; look through the right hand hole in the vane I, and through the transparent part of the glass F, for the horizon; and if it lies in the same right line with the image of the horizon, seen on the quicksilvered part, the glass F is rightly adjusted; but, if the two horizon lines disagree, turn the screw at the end of the handle backwards or forwards, until those lines coincide, then fasten the middle screw of the handle, and the glass is rightly adjusted.

To take the sun's altitude by the fore-observation: having fixed the screens above the horizon-glass F, and suited them proportionally to the strength of the sun's rays, turn your face towards the sun, holding the instrument with your right hand, by the braces L, M, in a vertical position, with the arch downwards; put your eye close to the right hand hole in the vane I, and view the horizon through the

transparent part of the horizon-glass, F, moving at the same time the index D, with your left hand, till the reflex solar spot coincides with the line of the horizon; then the degrees counted from C, or that end next your body, will give the altitude of the sun at that time, observing to add or subtract 16 min. according as the upper or lower edge of the sun's reflex image is made use of. But to obtain the sun's meridian altitude, which is the thing wanted, in order to find the latitude; the observations must be continued, and, as the sun approaches the meridian, the index D must be continually moved towards B, in order to maintain the coincidence between the reflex solar spot and the horizon; and consequently, as long as this motion can maintain the same coincidence, the observation must be continued, and when the sun has attained the meridian, and begins to descend, the coincidence will require a retrograde motion of the index, or towards C; and then is the observation finished, and the degrees counted, as before, will give the sun's meridian altitude, or those from B, the zenith distance; observing to add  $16' = \text{semidiam. } \odot$ , if the sun's lower edge is brought to the horizon; or to subtract  $16'$ , when the horizon and upper edge coincide.

To take the altitude of a star by the fore-observation: through the vane H, and the transparent slit in the glass G, look directly to the star; and at the same time move the index, till the image of the horizon behind you being reflected by the great speculum, is seen in the quick-silvered part of G, and meets the star; then will the index shew the degrees of the star's altitude.

To rectify the instrument for the back-observation: slacken the screw in the middle of the handle, behind the glass G; turn the button *b* on one side, and bring the index as many degrees before *a*, as is twice the dip of the horizon at your height above the water; hold the instrument vertical with the arch downwards, look through the hole of the vane H, and if the horizon seen through the transparent slit in the glass G, coincides with the image of the horizon, seen in the quick-silvered part of the same glass; then the glass G is in its proper position. But, if not, set it by the handle, and fasten the screw as before.

To take the sun's altitude by the back-observation: put the stem of the screens K, K, into the hole *r*, and, in proportion to the strength or faintness of the sun's rays, let one, both, or neither of the frames of those glasses be turned close to the face of the limb; hold the instrument in a vertical position, with the arch downwards, by the braces L, M, with your left hand; turn your back towards the sun, and put your eye close to the hole, in the vane H, observing the horizon through the transparent slit in the horizon-glass G; with your right hand move the index D, till the reflected image of the

the sun be seen in the quick-silvered part of the glass G, and in a right line with the horizon; swing your body to and fro, and if the observation be well made, the sun's image will be observed to brush the horizon, and the degrees reckoned from C, or that part of the arch farthest from your body, will give the sun's altitude, at the time of observation; observing to add 16 min. = the sun's semidiameter, if the sun's upper edge be used; and subtract 16. min. from the altitude, if the observation respected the lower edge.

The directions here given, especially if joined with those delivered under the article LATITUDE, (which see) for taking of altitudes at sea, would be sufficient, were there not two corrections necessary to be made, before the altitude can be accurately assigned, viz. one on account of the observer's eye being raised above the level of the sea, and the other on account of the refraction occasioned in small altitudes, by the haziness of the atmosphere.

We shall therefore give a table, shewing the corrections necessary to be made to altitudes on both these accounts, whether it be taken by Davis's or Hadley's quadrant, or any other instrument.

| Height of the eye in feet. | Corrections in minutes. | Altitude in degrees. | Corrections in minutes. | Altitude in degrees. | Corrections in minutes. |
|----------------------------|-------------------------|----------------------|-------------------------|----------------------|-------------------------|
| 5                          | 2'                      | 1                    | 23'                     | 12                   | 4'                      |
| 10                         | 3'                      | 2                    | 17 $\frac{1}{2}$ '      | 15                   | 3 $\frac{1}{2}$ '       |
| 15                         | 4'                      | 3                    | 14'                     | 20                   | 2 $\frac{1}{2}$ '       |
| 20                         | 5'                      | 4                    | 11'                     | 25                   | 2'                      |
| 25                         | 5 $\frac{1}{2}$ '       | 5                    | 9'                      | 30                   | 1 $\frac{1}{2}$ '       |
| 30                         | 6'                      | 6                    | 8'                      | 35                   | 1 $\frac{1}{2}$ '       |
| 35                         | 6 $\frac{1}{2}$ '       | 7                    | 7'                      | 40                   | 1'                      |
| 40                         | 7'                      | 8                    | 6'                      | 50                   | 0 $\frac{3}{4}$ '       |
| 45                         | 7 $\frac{1}{2}$ '       | 9                    | 5 $\frac{1}{2}$ '       | 60                   | 0 $\frac{1}{2}$ '       |
| 50                         | 8'                      | 10                   | 5'                      | 70                   | 0 $\frac{1}{4}$ '       |

General rules for using this table of corrections:

1. In the fore-observations, add the sum of the corrections to the observed zenith-distance, for the true zenith-distance; or, take the sum of the corrections from the observed altitude, and the remainder will be the altitude. 2. In the back-observations, add the dips, or corrections for the height of the eye, and subtract the refractions, for altitudes; and for zenith distances, subtract the dips, and add the refractions.

Example: By a back-observation, the altitude of the sun's lower edge was found by Hadley's quadrant to be  $25^{\circ} 12'$ ; the eye being 30 feet above the horizon. By the table, the dip on 30 feet is 6, and the refraction on  $25^{\circ}$  is 2'; therefore  $25^{\circ} 12' - 16' (= \text{semidiam. } \odot) = 24^{\circ} 56'$  and  $24^{\circ} 56' + 6'$  (by

rule 2.) =  $25^{\circ} 2'$ ; and lastly,  $25^{\circ} 2' - 2'$  (by rule 2.) =  $25^{\circ} =$  the true or corrected altitude.

We have been the more particular in our description and use of Hadley's quadrant, as it is undoubtedly the best hitherto invented.

QUADRANT of Altitude, is an appendage of the artificial globe, consisting of a lamina, or slip of brass, the length of a quadrant of one of the great circles of the globe and graduated. At the end, where the division terminates, is a nut riveted on, and furnished with a screw, by means whereof the instrument is fitted on to the meridian, and moveable round upon the rivet, to all points of the horizon.

Its use is to serve as a scale in measuring altitudes, amplitudes, azimuths, &c. See GLOBE.

QUADRANTAL, in Roman antiquity, a vessel every way square like a die, serving as a measure of liquids: its capacity was eighty libræ or pounds of water, which made forty-eight sextaries, two urnæ, or eight congi.

QUADRANTAL TRIANGLE, a spherical triangle, one of whose sides at least is a quadrant of a circle, and one of its angles a right-angle. See the article TRIANGLE.

QUADRAT, *Quadratum*, a mathematical instrument, called also a geometrical square, and line of shadows: it is frequently an additional member on the face of the common quadrant, as also on those of Gunter's and Sutton's quadrants.

QUADRAT, in astrology, the same with quartile. See QUARTILE.

QUADRAT, in printing, a piece of metal cast like the letters, to fill up the void spaces between words, &c.

There are quadrats of different sizes, as  $m$  quadrats,  $n$  quadrats, &c. which are respectively of the dimensions of these letters.

QUADRATA LEGIO, a square legion, in Roman antiquity, one consisting of four thousand men. See LEGION.

QUADRATIC EQUATION, in algebra, that wherein the unknown equality is of two dimensions, or raised to the second power. See EQUATION and POWER.

Construction of QUADRATIC EQUATIONS. See CONSTRUCTION.

QUADRATING of a Piece, among gunners, is the due placing of a piece of ordnance, and poising it in its carriage, and having its wheels of an equal height, &c. See the article GUNNERY.

QUADRATO-CUBUS, *Quadrato Quadrato-Cubus*, and *Quadrato-Cubo-Cubus*, according to Diophantus, Vieta, Oughtred, &c. denotes the fifth, seventh, and eighth powers. See POWER.

QUADRATO-*Quadratum*, or *Biquadratum*, the fourth power of numbers, or the product of the cube when multiplied by the root.

**QUADRATRIX**, in geometry, a mechanical line, by means whereof we can find right-lines equal to the circumference of circles, or other curves, and their several parts.

**QUADRATRIX** of *Dinostrates*, so called from its inventor *Dinostrates*, is a curve, whereby the quadrature of the circle is effected mechanically.

**QUADRATRIX** *Tschirnhaufiana*, is a transcendental curve invented by M. *Tschirnhausen*, whereby the quadrature of the circle is likewise effected.

**QUADRATUM - CUBI**, *Quadrato-Quadrato-Quadratum*, and *Quadratum-Surdesolidi*, according to the Arabs, denote the sixth, eighth, and tenth powers of numbers. See the article **POWER**.

**QUADRATURE**, *Quadratura*, in geometry, denotes the squaring, or reducing a figure to a square. Thus, the finding of a square, which shall contain just as much surface or area as a circle, an ellipsis, a triangle, &c. is the quadrature of a circle, ellipsis, &c.

**QUADRATURE**, in astronomy, that aspect of the moon when she is  $90^\circ$  distant from the sun; or when she is in a middle point of her orbit, between the points of conjunction and opposition, namely, in the first and third quarters. See **MOON**.

**QUADRATURE-Lines**, are two lines placed on Gunter's sector: they are marked with Q. and 5, 6, 7, 8, 9, 10; of which Q. signifies the side of the square, and the other figures the sides of polygons of 5, 6, 7, &c. sides. S. on the same instrument, stands for the semi-diameter of a circle, and 90 for a line equal to  $90^\circ$  in circumference.

**QUADRATUS**, in anatomy, a name given to several muscles on account of their square figure.

**QUADREL**, in building, a kind of artificial stone, so called from its being perfectly square.

The quadrels are made of a chalky earth, &c. and dried in the shade for two years. These were formerly in great request among the Italian architects.

**QUADRILATERAL**, in geometry, a figure whose perimeter consists of four right-lines, making four angles; whence it is also called a quadrangular figure.

The quadrilateral figures are either a parallelogram, trapezium, rectangle, square, rhombus, or rhomboides.

**QUADRIL**, *Quadrilla*, a little troop or company of cavaliers, pompously dressed, and mounted for the performance of carousals, jousts, tournaments, runnings at the ring, and other gallant divertisements.

**QUADRILLE**, a game at cards, sometimes called ombre by four; which chiefly differs from ombre by three, in being played by four persons, and having all the forty cards dealt out, to each person, at ten each. See **OMBRE**.

**QUADRUPEDS**, *Quadrupedia*, in zoology, a class of land-animals, with hairy bodies, and four

limbs or legs proceeding from the trunk of their bodies: add to this, that the females of this class are viviparous, or bring fourth their young alive, and nourish them with milk from their teats.

**QUADRUPLE**, a sum or number multiplied by four, or taken four times.

This word is particularly used for a gold coin, worth four times as much as that whereof it is the quadruple.

**QUAKERS**, a religious sect, which made its first appearance in England during the interregnum; so called, in derision, from certain unusual tremblings with which they were seized at their first meetings.

Their founder was George Fox, a shoe-maker, born at Draiton, in Leicestershire; who, as he worked at his trade, used to meditate much on the Scriptures: at length he began to see visions, and set up for a preacher.

He proposed but few articles of faith, insisting chiefly on moral virtue, mutual charity, the love of God, and a deep attention to the inward motions and secret operations of the spirit. He required a plain simple worship, and a religion without ceremonies, making it a principal point to wait in profound silence the directions of the Holy Spirit.

Quakers were at first guilty of some extravagancies, but these wore off, and they settled into a regular body, professing great austerity of behaviour, a singular probity and uprightness in their dealings, a great frugality at their tables, and a remarkable plainness and simplicity in their dress.

The system of the Quakers is laid down in fifteen theses, by Robert Barclay, in a sensible well-wrote apology, addressed to Charles II.

Their principal doctrines are, That God has given to all men, without exception, supernatural light, which, being obeyed, can save them; and that this light is Christ, the true light, which lighteth every man that cometh into the world. That the Scriptures were indeed given by inspiration, and are preferable to all the other writings in the world; but that they are no more than secondary rules of faith and practice, in subordination to the light or spirit of God, which is the primary rule. That immediate revelation is not ceased, a measure of the spirit being given to every one. That all superstitions and ceremonies in religion, of mere human institution, ought to be laid aside; as also, in civil society, the saluting one another by pulling off the hat, bowing, or the like; and the saying *you*, instead of *thou*, to a single person. That men and women ought to be plain and grave in their apparel, sober and just in their whole conversation, and, at a word, in all their dealings; and not to swear, to go to war, to fight in private quarrels, or even to bear any carnal weapons.

They also entirely set aside the two sacraments, baptism, and the Lord's-supper; admit no clergy among them, but any one, without distinction, who

who is of a sober life, and believes him or herself to be moved thereto by the Spirit, is allowed to preach in their assemblies; and they hold it unlawful to pay tythes, or church-rates. In short, they are a quiet inoffensive people, of exemplary morals, remarkably charitable and friendly to each other, and have never yet been guilty of persecution, though they have had it in their power.

As to the discipline and polity, the affairs of the community are managed in their assemblies, of which there are several kinds; as monthly, quarterly, yearly, second day's meetings, and meetings of sufferings. The monthly and quarterly meetings are held in their respective counties, to which deputies are sent from the several particular meetings, and enquiry is made into the state of each meeting; who violate the laws of the community; who pay tythes or church-rates, and who suffer for the non-payment of either: here too they excommunicate, and receive again into their communion. Of all which registers are kept.

From these meetings appeals lie to their yearly assemblies, which are always held in London, and consist of three orders or classes; representatives sent from the quarterly meetings, correspondents from foreign countries and the several counties, and preachers. Hither are transmitted accounts of what has been transacted in all the monthly and quarterly meetings: here measures are concerted, and directions given as to behaviour about tythes, rates, &c. and here they compose differences and make provisions for the poor: here public accounts are audited, and instructions given to the deputies to be observed at their return; and from hence a yearly epistle of admonition is dispatched, to be read in all the monthly and quarterly meetings.

The second day's meeting is a standing committee, consisting of the principal preachers in and about the city, who meet every Monday to consider of particular cases and exigencies which happen between the yearly meetings.

The meeting of sufferings is held every week, and consists of the correspondents for each county. Its business is to receive complaints from such as have suffered for non-payment of tythes and church-rates, and to procure them relief, either by sending them money, for which they have a settled fund, or by soliciting their cause, or both.

**QUALIFICATOR**, in the canon-law, a divine appointed to qualify, or declare the quality of a proposition brought before an ecclesiastical tribunal, chiefly before the inquisition. The qualificators of the office are not judges, they only give their sentiments on the proposition presented to them.

**QUALITY**, *Qualitas*, is defined by Mr. Locke, to be the power in a subject of producing any idea in the mind: thus a snow-ball having the power to produce in us the ideas of white, cold, and round, these powers, as they are in the snow-ball, he calls

qualities; and as they are sensations, or perceptions, in our understanding, he calls ideas. See the article Idea.

**QUANTITY**, *Quantitas*, any thing capable of estimation, or mensuration; or which, being compared with another thing of the same kind, may be said to be greater or less than it, equal or unequal to it.

Mathematics is the science or doctrine of quantity, which being made up of parts, is capable of being made greater or less. It is increased by addition, and diminished by subtraction; which are therefore the two primary operations that relate to quantity. Hence it is said that any quantity may be supposed to enter into algebraic computations two different ways, which have contrary effects, viz. either as an increment or as a decrement. See the articles ADDITION and SUBTRACTION.

As addition and subtraction are opposite, or an increment is opposite to a decrement, there is an analogous opposition between the affections of quantities that are considered in the mathematical sciences; as between excess and defect, between the value of effects or money due to a man, and money due by him; a line drawn towards the right, and a line drawn towards the left; gravity, and levity; elevation above the horizon, and depression below it. When two quantities equal in respect of magnitude, but of those opposite kinds, are joined together, and conceived to take place in the same subject, they destroy each other's effect, and their amount is nothing. A power is sustained by an equal power, acting on the same body with a contrary direction, and neither have effect. When two unequal quantities of those opposite qualities are joined in the same subject, the greater prevails by their difference; and when a greater quantity is taken from a less of the same kind, the remainder becomes of the opposite kind. When two powers or forces are to be added together, their sum acts upon the body; but when we are to subtract one of them from the other, we conceive that which is to be subtracted, to be a power with an opposite direction; and if it be greater than the other, it will prevail by the difference. This change of quality only takes place where the quantity is of such a nature as to admit of such a contrariety or opposition. We know nothing analogous to it in quantity abstractedly considered; and cannot subtract a greater quantity of matter from a lesser, or a greater quantity of light from a lesser; and the application of this doctrine to any art or science, is to be derived from the known principles of the science. See the articles ALGEBRA, GEOMETRY, &c.

A quantity that is to be added, is called a positive quantity; and a quantity to be subtracted, is said to be negative. See the articles POSITIVE and NEGATIVE.

Quan-

Quantities are said to be like or similar, that are of the same denomination, or are represented by the same letter or letters, equally repeated: but quantities of different denominations, or represented by a different letter or letters, are said to be unlike or dissimilar. A quantity consisting of more than one term, is called a compound quantity; whereas that consisting of one term only, is denominated a simple quantity.

The quantity of matter in any body, is the product of its density into its bulk; or a quantity arising from the joint consideration of its magnitude and density; as if a body be twice as dense, and take up twice as much space as another, it will be four times as great. This quantity of matter is best discoverable by the absolute weight of bodies. See GRAVITY.

The quantity of motion in any body is the factum of the velocity into the mass, or it is a measure arising from the joint consideration of the quantity of matter, and the velocity of the motion of a body; the motion of any whole being the sum or aggregate of the motion in all its several parts. Hence, in a body twice as great as another, moved with an equal velocity, the quantity of motion is double; if the velocity be double also, the quantity of motion will be quadruple. Hence, the quantity of motion is the same with what we call the momentum or impetus of a moving body. See the article MOTION.

QUANTITY, in grammar, an affection of a syllable, whereby its measure, or the time wherein it is produced, is ascertained; or that which determines the syllable to be long or short. See the articles MEASURE and SYLLABLE.

Quantity is also the object of prosody, and distinguishes verse from prose; and the œconomy and arrangement of quantities, that is, the distribution of long and short syllables, makes what we call the number.

Combination of QUANTITIES. See the article COMBINATION.

Commensurable QUANTITIES. See the article COMMENSURABLE.

Exponential QUANTITY. See the article EXPONENTIAL.

Infinite QUANTITIES. See the articles INFINITE QUANTITIES, and INFINITESIMALS.

QUANTUM MERUIT, in law, is an action upon the case, founded on the necessity of paying a person, for doing any thing, as much as he deserves.

QUARANTAIN, QUARENTINE, or QUARANTENA, in old law books, denotes the space of forty days. It also signifies a benefit allowed to the widow of a man dying seized of lands, &c. by which she may challenge to continue in his capital messuage, or chief mansion house, so it be not a castle, for the space of forty days after his decease.

And if the heir or any other person eject her, she may have the writ de quarantena habenda.

QUARANTAIN is more particularly used for a term of forty days, which vessels, coming from places suspected of contagion, are obliged to wait in certain places appointed to air themselves, before they come into port. See the article LAZAR-HOUSE.

Quarantain, also signifies a measure or extent of land, containing forty perches.

QUARANTAIN of the King, in France, denotes a truce of forty days, appointed by St. Louis, during which it was expressly forbid to take revenge on the relations or friends of people, who had fought, wounded, or affronted each other in words.

QUARREL, *Querela*, in law, is generally applied to personal and mixed actions, in which the plaintiff is called querens: and hence it is that if a person release all quarrels, it is taken to be as beneficial to the releasee, as if it were a release of all actions; since all actions, both real and personal, are thereby released.

QUARREL of Glasi. See the next article.

QUARRY, a place under ground, out of which are got marble, free-stone, slate, lime-stone, or other matters proper for buildings.

Quarries of free-stone, are in many places opened, and the stone brought out, in the following manner: they first dig a hole in the manner of a well, twelve or fourteen feet in diameter, and the rubbish drawn out with a windlass in large osier baskets, they heap up all around; placing their wheel, which is to draw up their stones, upon it. As the hole advances, and the common ladder becomes too short, they apply a particular ladder for the purpose. When they have got through the earth, and are arrived at the first bank or stratum, they begin to apply their wheel and baskets to discharge the stones as fast as they dig through them. In freeing the stone from the bed, they proceed thus: as common stones, at least the softer kinds, have two grains, a cleaving grain, running parallel with the horizon, and a breaking grain, running perpendicular thereto; they observe by the grain where it will cleave, and there drive in a number of wedges, till they have cleft it from the rest of the rock. This done, they proceed to break it; in order to which, applying the ruler to it, they strike a line, and by this cut a little channel with their stone-ax; and in the channel, if the stone be three or four feet long, set five or six wedges, driving them in very carefully with gentle blows, and still keeping them equally forward. Having thus broken the stone in length, which they are able to do of any size within half an inch, they apply a square to the straight side, strike a line, and proceed to break it in breadth. This way of managing stone is found vastly preferable to that where they are broken at random; one load of the former being found to do the business of a load and

# QUA

and a half of the latter. But it may be observed, that this cleaving grain being generally wanting in the harder kinds of stones, to break up these in the quarries, they have great heavy stone-axes, with which they work down a deep channel into the stone; and into this channel, at the top, lay two iron bars, between which they drive their iron wedges.

Some in dividing the stone, especially the very hard kinds, make use of gun-powder, with very good effect. In order to which, making a small perforation pretty deep in the body of the rock, so as to have that thickness of rock over it judged proper to be blown up at once, at the further end of the perforation they dispose a convenient quantity of gunpowder, filling up all the rest with stones and rubbish, strongly rammed in, except a small place for the train. By this means is the rock blown into several pieces, most of which are not too big to be managed by the workmen.

**QUARRY**, or **QUARREL**, among glaziers, a pane of glass cut in a diamond form.

Quarries are of two kinds, square and long, each of which are of different sizes, expressed by the number of the pieces that make a foot of glass, viz. eighths, tenths, twelfths, eighteenth, and twentieths :

**QUARRY**, in falconry, is the game which the hawk is in pursuit of, or has killed.

**QUART**, a measure containing the fourth part of some other measure. See the article **MEASURE**.

The English quart is the fourth part of a gallon, or two pints. See the articles **GALLON** and **PINT**.

**QUARTAN**, *Quartana*, in medicine, a species of intermitting fever, wherein the patient has two fits in four days, or two days quite free from a fit.

It usually begins about four or five in the afternoon, sometimes sooner and sometimes later, with a great lassitude, stretching, a blunt pain in the head, back, loins, and legs; the feet and hands are cold, and the whole body is pale; and the face and nails livid, to which shivering and shaking supervene. The tongue and the lips tremble, the breathing is difficult, with restlessness, and tossing; the pulse is contracted and hard, and sometimes unequal; and there is an anxiety about the præcordia. These symptoms continue about two or three hours; and in some the body is costive, whereas in others there is a stimulus to stool, and to make water; in some again, there is a nausea or vomiting, with stools; and some advanced in years, have their minds pretty much disturbed. The heat comes on gradually, not burning but dry; the pulse becomes equal, quick, and large, but the dull pain in the head remains, with a vertiginous affection; the skin becomes only a little moist; and in about four or six hours,

# QUA

the symptoms vanish except a dull pain in the bones, joints, and feet. The urine in the fit is sometimes thin and watery, and sometimes thick with a sediment.

From the experiments of Dr. Langrish it appears, that the blood is more dense and tenacious in quotidians than in tertians, and in tertians than in quartans. See **QUOTIDIAN** and **TERTIAN**.

As to the cure, a vomit should be given after the first fit, in the time of intermission: in tender constitutions, ipecacuanha may be given alone, or two ounces of vinum ipecacuanhum; but to the robust, a grain or two of emetic tartar may be added, to be taken in warm water about two hours after the paroxysm. The evacuation should be facilitated by taking large draughts of water-gruel made fat with fresh butter. Then take the following electuary, which will crush the disease in the bud: viz. take of rob of elder, one ounce; of peruvian bark, five drams; of the powder of common chamomile-flowers, two drams; of the extract of lesser centaury, and powder of clove-julyflowers, each half a dram; and as much syrup of lemons as is sufficient to reduce them to the form of an electuary. The dose is half a dram, to be taken every two hours after the fit.

If any thing forbids vomiting, the cure must be begun with detergent and aperient salts, as vitriolated tartar, salt ammoniac, purified nitre, and crab's eyes; and if the ague still continue, notwithstanding the repeated use of these salts, then an equal weight of peruvian bark must be added to them, or the above electuary may be given.

When the patient is subject to the hypochondriac passion, the stomach is inflated, and the body costive; then neither vomits nor salts must be ventured upon, but carminative and emollient clysters.

In obstinate quartans, Hoffman greatly commends the following medicine: take of peruvian bark, three drams; of medicinal regulus of antimony, two drams; of mercurius dulcis, (which is not to be triturated with the powder on account of the salts, but only mixed with the point of a knife) of the finest crocus martis, and of vitriolated nitre, each one dram: and of oil of mint, four drops: make up all these into a powder, of which half a dram, or a dram, may be taken, made into the form of a bolus, with rob of elder, and syrup of clove-julyflowers.

This method is confirmed by Huxam, who says the bark frequently proves ineffectual, without the help of proper alexipharmacs; as snake-root of Virginia, contrayerva, myrrh, camphor &c. After four or five paroxysms, warm chalybeates may be added with very great success; but when the patient's complexion has a yellow cast, and he has a tense abdomen, and a very costive habit of body, mercurial, saponaceous deobstruents, with rhubarb, aloetics, or sal diureticus should be premised to, or joined with the bark. Hoffman observes, that

obstinate quartans in boys are not to be cured but by purging; and therefore, he directs the following form: take of cream of tartar, one dram; of calx of antimony, twelve grains; of sulphurated diargyrium, six grains; make them into a powder, which may be taken in three doses, the first six hours before the fit, the second before the next fit, and the third before the third fit. After this, he orders an infusion of half an ounce of peruvian bark in eight ounces of fennel-water; adding the bark of Eleutherius, sal diureticus, and salt of tartar, of each one dram, together with half an ounce of syrup of clove-julyflowers; a spoonful of which should be taken every two hours.

To prevent the return of an ague, the bark must be repeated every week or ten days, for three several times, with the same intervals. Likewise bitters and chalybeates are very serviceable, taken either together or separately.

**QUARTATION**, in metallurgy, a method of purifying gold, by melting three parts of silver with one of gold, and then throwing the mixture into aquafortis. See the article **ASSAYING**.

**QUARTER**, *Quadrans*, the fourth part of any thing, the fractional expression for which is  $\frac{1}{4}$ . See the article **FRACTION**.

**QUARTER**, in weights, is generally used for the fourth part of an hundred weight averdupois, or 28lb. See **WEIGHT**.

Used as the name of a dry measure, quarter is the fourth part of a ton in weight, or eight bushels. See the articles **MEASURE** and **TON**.

**QUARTER**, in law, the fourth part of a year; and hence the days on which these quarters commence, are called quarter-days, viz. March 25, or Lady-day; June 24, or Midsummer-day; September 29, or Michaelmas; and December 21, or St. Thomas the apostle's day. On these days rents on leases, &c. are usually reserved to be paid; though December 25, or Christmas-day, is commonly reckoned the last quarter-day.

**QUARTER**, in astronomy, the fourth part of the moon's period: thus, from the new moon to the quadrature is the first quarter; from this to full moon, the second quarter, &c. See **PHASIS** and **MOON**.

**QUARTER**, in heraldry, is applied to the parts or members of the first division of a coat that is quartered, or divided into four quarters. See **QUATERING**.

**Franc-QUARTER**, in heraldry, is a quarter single or alone; which is to possess one fourth part of the field.

This makes one of the honourable ordinaries of a coat.

**QUARTER of a Point**, in navigation, is the fourth part of the distance between two cardinal points, which is  $2^{\circ} 48'$ .

**QUARTER of a ship**, is that part of a ship's hold,

which lies between the steerage-room and the transom.

**Cloze-QUARTERS**, in a ship, those places where the seamen quarter themselves, in case of boarding, for their own defence, and for clearing the decks, &c.

**QUARTER-DECK**. See **DECK**.

**QUARTER-MASTERS**, or **QUARTEERS**, in a man of war, are officers whose business is to rummage, stow, and trim the ship in the hold; to overlook the steward in his delivery of victuals to the cook, and in pumping or drawing out beer, or the like. They are also to keep their watch duly, in conning the ship, or any other duty.

**QUARTER**, in war, is used in various senses, as for the place allotted to a body of troops to encamp upon: thus they say, the general has extended his quarters a great way, &c. **Quarter** also signifies the sparing mens lives: thus it is said, the enemy asked quarter: we gave no quarter.

**QUARTER of an Assembly**, is the place of rendezvous, where the troops are to meet and draw up in a body.

**Head-QUARTERS**, is the place where the general of an army has his quarters, which is generally near the center of the army.

**QUARTERS of Refreshment**, is the place to which the troops that have been much fatigued are sent to refresh themselves, during a part of the campaign.

**Winter-QUARTERS**, the places in which the troops are lodged during the winter, or their residence in those places.

**QUARTER-Master**, an officer in the army, whose business is to look after the quarters of the soldiers; of which there are several kinds, viz. The quarter-master general, whose business is to provide good quarters for the whole army. Quarter-master of horse, he who is to provide quarters for a troop of horse. Quarter-master of foot, he who is to provide quarters for a regiment of foot.

**QUARTER**, in the manege, as to work from quarter to quarter, is to ride a horse three times in upon the first of the four lines of a square; then changing your hand, to ride him three times upon the second; and so to third and fourth; always changing hands and observing the same order.

**QUARTER-Chord**, in mining, is seven yards and a quarter, which the miner has cross-ways of his vein, on either side, for liberty to lay his earth, stones, and rubbish on, and to wash and dress up his ore.

**QUARTERS**, in building, are those slight upright pieces of timber placed between the puncheons and posts, used to lath upon.

These are of two sorts, single and double; the single quarters are sawn to two inches thick, and four inches broad; the double quarters are sawn to four inches square.

# QUA

It is a rule in carpentry, that no quarters be placed at a greater distance than fourteen inches.

**QUARTER-Round**, in architecture, is a term used by the workmen for any projecting moulding in general, whose contour is a perfect quadrant of a circle, or which approaches near that figure.

**QUARTER-Wheeling**, or **QUARTER of Conversion**, in the military art, is the motion by which the front of a body of men is turned round to where the flank was, by taking a quarter of a circle.

If it be done to the right, the man in the right-hand angle keeps his ground and faces about, while the rest wheel; if to the left, the left-hand man keeps his place.

**QUARTER-Wind**, at sea, is a lateral or side-wind, which does not blow in stern, but a little aside of it.

This is the best of all winds, as bearing into all the sails; whereas a wind blowing full in stern, is kept off by the sails of the mizzen.

**QUARTERING**, in the sea-language, is disposing the ships company at an engagement, in such a manner as that each may readily know where his station is, and what he is to do.

As some to the master for the management of the sails; some to assist the gunners in traversing the ordnance; some for plying of the small shot; some to fill powder in the powder-room: others to carry it from thence to the gunners, in carthrages, &c.

When a ship under sail goes at large, neither by a wind, nor before a wind, but, as it were, betwixt both, she is said to go quartering.

**QUARTERING**, in gunnery, is when a piece of ordnance is so traversed that it will shoot on the same line, or on the same point of the compass as the ship's quarter bears.

**QUARTERING**, in heraldry, is dividing a coat into four or more quarters, or quarterings, by parting, coupling, &c. that is, by perpendicular and horizontal lines, &c.

**Counter-QUARTERING a Coat**, is when the quarters are subdivided each into four.

There are counter-quartered coats that have twenty or twenty-five quarters.

**QUARTERING**, or **QUARTERIZATION**, is part of the punishment of a traitor, which consists of dividing his body into four quarters.

**QUARTERLY**, in heraldry. A person is said to bear quarterly, when he bears arms quartered. See **QUARTERING**.

**QUARTERN**, a diminutive of quart, signifying a quarter of a pint.

**QUARTILE**, an aspect of the planets. See **ASPECT**.

**QUARTO**, or 4to, a book of which four leaves, or eight pages, make a sheet.

**QUARTO-DECIMANS**, *Quarto-decimani*, an ancient Christian sect, so called from their maintain-

# QUA

ing that the festival of Easter ought to be celebrated, conformably to the custom of the Jews, on the fourteenth day of the moon in the month of March, whatever day of the month that happened to be.

**QUASHING**, in law, the overthrowing or annulling of any thing.

**QUASSIA**, in botany, a genus of decandrious plants, whose flower consists of five lanceolated, long, sessile petals, with five ovate, hairy, squamous nectariums: there are five pericarpiums inserted into an orbicular fleshy receptacle, and the seeds are solitary and globose.

**QUARTER-COUSINS**, fourth cousins, or the last degree of kindred.

**QUAVER**, in music, a measure of time equal to half a crochet, or an eighth of a semibreve.

The quaver is divided into two semiquavers, and four demisemiquavers. See **CHARACTERS in Music**.

**QUAVERING**, in music, trilling or shaking; or the running a division with the voice.

**QUAY**, or **KAY**. See **WHARF**.

**QUEEN**, *Regina*, a woman who holds a crown singly.

The title of Queen is also given by way of courtesy to her that is married to a king, who is called by way of distinction queen consort; the former being termed queen regent. The widow of a king is also called queen; but with the addition of dowager.

**QUERCUS**, the oak-tree, in botany. See the article **OAK**.

**QUERIA**, in botany, a genus of plants, whose flower hath no corolla; the calyx is erect and persistent, and divided into five oblong acute segments; the outward ones are recurved; the stamina are three short hairy filaments, topped with roundish antheræ. The fruit is a roundish trivalvular capsule, with one cell containing a single seed.

**QUESTION**, *Quæstio*, in logic, a proposition proposed by way of interrogation. See the article **PROPOSITION**.

**QUESTOR**, or **QUÆSTOR**, in Roman antiquity, an officer who had the management of the public treasure.

**QUEUE**, in heraldry, signifies the tail of a beast: thus if a lion be borne with a forked tail, he is blazoned double queued.

**QUEUE D'ARONDE**, or **SWALLOW'S TAIL**, in fortification, an outwork which is narrower at the gorge than at the front or face, being so called from its resemblance to a swallow's tail.

Of this kind are some single as well as double tenailles, and some horn-works whose sides are not parallel. See the articles **TENAILE** and **HORN-WORK**.

When the front is narrower than the gorge, the work is denominated a contre queue d'aronde.

# QUI

In carpentry, a *que d'aronde* is more generally known by the name of *dove-tail*. See *DOVE-TAIL*.

**QUICK**, or **QUICKSET**, among gardeners, the hawthorn, or *mespilus sylvestris*, much used for hedges, it being very proper for that purpose. In the choice of quick, those which are raised from seeds in the nursery are preferable to such as are drawn from the woods, the latter seldom arising with good roots; but to have the best quick fence, it is most eligible to sow the haws where the hedge is intended; for these unremoved plants will make a much stronger and more durable fence than those which are transplanted; but they should be properly weeded when young, and protected from being injured by cattle, &c. When quick is grown rude, and bare at bottom, it may be necessary to plash it; of which method there are two extremes to be avoided; the first is, laying it too low and too thick; because it makes the sap run all into the shoots, and leaves the plashes without nourishment, which, with the thickness of the hedge, kill them: secondly, it must not be laid too high, because this draws all the sap into the plashes, and so causes but small shoots at the bottom, so that the hedge is still thin, without answering the intention of plashing. When the shoot that is designed to be plashed is bent, there is generally given a small cut to it half way through, and sloping a little downward, then it is wove about the stakes, and trimmed of its straggling superfluous branches. See the articles *FENCE* and *HEDGE*.

**QUICK-BEAM**, *Sorbus*, in botany. See the article *SORBUS*.

**QUICK-SILVER**, in natural history, a ponderous mineral fluid, more usually called mercury. See the article *MERCURY*.

**QUID**, a term used in the schools for the definition of a thing; which is thus called as answering to the question, *quid est?* what is it. See *DEFINITION*.

**QUIDDITY**, *Quidditas*, a barbarous term used in the schools for essence.

**QUIESCENT**, something at rest, in contradistinction to motion. See the articles *REST* and *MOTION*.

**QUIETISTS**, a religious sect, which made a great noise towards the close of the last century.

They were so called from a kind of absolute rest and inaction, which they supposed the soul to be in when arrived at that state of perfection which they called the unitive life; in which state they imagined the soul wholly employed in contemplating its God, to whose influence it was entirely submissive, so that he could turn and drive it where and how he would. In this state, the soul no longer needs prayers, hymns, &c. being laid, as it were, in the bosom, and between the arms of its God, in whom it is in a manner swallowed up.

# QUI

**QUIETUS**, in law is the same as freed or acquitted; being used by the clerk of the pipe, and auditors in the exchequer, in their discharges given to accounts; which generally conclude with these words, *abinde recessit quietus*, and is termed a *quietus est*; and being granted to the sheriff, discharges him of all accounts due to the king.

**QUILLS**, the large feathers taken out of the end of the wing of a goose, crow, &c.

Quills are denominated from the order in which they are fixed in the wing, the second and third quills being the best for writing, as they have the largest and roundest barrels.

**QUILTING**, a method of sewing two pieces of silk, linen, or stuff, on each other, with wool or cotton between them; by working them all over in the form of chequer or diamond-work, or in flowers. The same name is also given to the stuff so worked.

**QUINARIUS**, in Roman antiquity, a small coin equal to half the denarius.

**QUINCE**, *Cydonia*, in botany, a well known genus of trees, comprehended by Linnæus among the *pyrus* or pear-tree, which, according to his system of botany, it agrees with, in respect of its generical characters. According to Pliny, it received the name of *malus cydonia* from Cydone, a town in Crete, from whence it is said to have been first brought into Italy.

Quince trees are of several kinds, as the pear-quince, the apple-quince, the Portugal-quince, &c. They are all easily propagated, either by layers, suckers, or cuttings, and require a moist soil; but is best when grafted, although it bears without it, for, by the check given to the sap thereby, it produces fruit much sooner, and in greater quantity. The season for planting quince-trees is in autumn. When quinces are unripe, they are seldom or never eaten, especially raw, as they are very rough and astringent; they mightily cool and strengthen the stomach, remove nausea, and stop fluxes of the belly; for these purposes they are much in use; especially their juice made into a syrup, which is both pleasant and agreeably astringent. The seeds bruised well with an aqueous liquor afford a good mucilage, which is excellent in some sorenesses of the mouth and gums.

**QUINCUNX**, in Roman antiquity, denotes any thing that consists of five twelfth parts of another, but particularly of the *as*. See the articles *UNCIA* and *AS*.

**QUINCUNX ORDER**, in gardening, a plantation of trees, disposed originally in a square; and consisting of five trees, one at each corner, and a fifth in the middle: or a quincunx is the figure of a plantation of trees, disposed in several rows, both length and breadthwise, in such a manner, that the first tree in the second row commences in the center of the square formed by the two first trees in the

# QUI

first row, and the two first in the third, resembling the figure of the five at cards. This disposition of trees was formerly much more regarded than at present; but is still much used in France, for planting trees to form a grove.

**QUINDECAGON**, in geometry, a plain figure with fifteen sides and fifteen angles; which, if the sides be all equal, is termed a regular quindecagon, and irregular when otherwise.

The side of a regular quindecagon inscribed in a circle, is equal in power to the half difference between the side of the equilateral triangle, and the side of the pentagon, inscribed in the same circle; also the difference of the perpendiculars let fall on both sides, taken together.

**QUINDECENVIRI**, in Roman antiquity, a college of fifteen magistrates, whose business it was to preside over the sacrifices.

They were the interpreters of the Sibyl's books; which, however, they never consulted but by an express order of the senate.

**QUINQUAGESIMA SUNDAY**, Shrove Sunday, so called as being the fiftieth day before Easter.

**QUINQUEFOLIUM**, cinquefoil, in botany, is comprehended by Linnæus under potentilla. See **POTENTILLA**.

**QUINQUINA**, in pharmacy, the same with the Peruvian or Jesuits bark; the tree which produces it is called by Linnæus cinchona. See the article **CINCHONA**.

The Peruvian bark should be chosen fresh, and of a bright colour, approaching to that of cinnamon, and of a strong taste. The smaller pieces, in quills, are generally the best; the larger and flatter fragments having less virtue. We sometimes meet with it cut into thin slices, and of a yellower colour than ordinary; this is the bark of the root, has a very strong taste, and is esteemed by the Spaniards the choicest of all.

The Peruvian bark possesses the stomachic virtues of the other bitters, and that in so eminent a degree, that it is a question whether any of the stomachics are equal to it: it strengthens the stomach, promotes the appetite, and assists digestion; it dissipates flatulencies, and is a very good medicine against worms. Its great virtue, however, is as a febrifuge: it cures all intermittents safely and speedily, if properly given. Its febrifuge virtue was discovered to us by the Indians, among whom it had been many ages known, and first discovered by a person's being cured of an intermittent, by drinking the water of a pond, where some trees of it had accidentally fallen. It was not discovered to any body in this part of the world till 1640, when a Spaniard, the governor of the city of Loxa, who had behaved well to some of these people, had the discovery as a reward. With the new medicine he cured the viceroy's lady of a tertian, after she had

# QUI

tried every thing else in vain. Hence it was called the countess's powder.

After this, the Jesuits brought over a vast quantity, which was, in 1694, distributed all over Europe, and did great cures. It was then called pulvis patrem, and Jesuit's powder; and the cardinal de Lugo having bought up a vast quantity of it for poor and others, it was afterwards called cardinal Lugo's powder.

Notwithstanding the success of this new febrifuge, whenever given properly, there were many of the physicians at that time, who were scrupulous of using it, as suspecting it could not be safe to carry off such a disease so speedily, and without evacuations; but a long and happy experience of it has taught us, that it is one of the greatest, and in prudent hands, one of the safest medicines in the world. It is given in powder from a scruple to a drachm for a dose. We have a simple, a volatile tincture, and an extract of it in the shops.

**QUINSEY**, or **QUINZY**. See the article **QUINZY**.

**QUINTAL**, in commerce, the same with hundred weight. See **WEIGHT**.

**QUINTESSENCE**, *Quinta Essentia*, in chemistry, a preparation consisting of the essential oil of some vegetable substance mixed and incorporated with spirit of wine.

**QUINTILE**, *Quintilis*, in astronomy, an aspect of the planets, when they are 72 degrees distant from one to another, or a fifth part of the zodiac.

**QUINTILLIANS**, a sect of ancient heretics, thus called from their prophets Quintilia. In this sect the women were admitted to perform the sacerdotal and episcopal functions. They attributed extraordinary gifts to Eve for having first eaten of the tree of knowledge; told great things of Mary the sister of Moses, as having been a prophetess, &c. They added, that Philip the deacon had four daughters, who were all prophetesses, and were of their sect. In these assemblies it was usual to see the virgins entering in white robes, personating prophetesses.

**QUINZY**, **QUINSEY**, or **ANGINA**, in medicine, a pain and inflammation of the fauces, a swelling of the uvula, tonsils, and larynx, which being accompanied by a fever, occasions a difficulty of respiration and deglutition. This disease generally prevails about the latter end of spring or beginning of summer. When the swelling, pain, and redness appear mostly on the outides, it is, according to Hoffman, the prognostic of a happy solution of the disease: but when the external swelling suddenly disappears, without a mitigation of the symptoms, it shews the morbid matter to be translated elsewhere, and that the disease will change to a phrenzy, or peripneumony. This disease may also terminate in a suppuration, gangrene, or schirrus. A

froth-

frothing at the mouth, the tongue vastly swelled, and of a purple, blackish colour, portend death.

The quincy is generally distinguished by modern writers into the idiopathic and symptomatic. The first, where it is itself the disease, and owes its origin only to a plethora; the second, where it is but the accidental symptom of an inflammatory fever, or some other disease, about the time of its crisis.

Dr. Mead distinguishes the quincy into three sorts; the first of which he calls the watery quincy; the second, a gangrene of the tonsils; and the third a strangulation of the fauces. In the first sort, the glands of the mouth, palate, and neighbouring parts are swoln. In the second, an inflammation without a perfect suppuration seizes the tonsils, which swell and grow hard; a gangrene soon ensues, which, if not speedily relieved, proves fatal.

In the third sort, all the nerves are convulsed, and the patient drops down dead suddenly: however, this species of the quincy, though described by Hippocrates, is yet very rare. If it can be foreseen, it ought to be prevented by evacuations of all kinds; that is, bleeding, purging, blistering, issues, and diuretics; and it will be of service to practise abstinence, or a moderation in eating and drinking. In the watery-quincy, which sometimes rages like an epidemic fever, especially in places near the sea, bleeding plentifully as soon as possible is recommended; afterwards clysters, gentle purges, blisters under the chin, and on the sides of the neck; and if this course does not succeed, the palate must be pretty deeply scarified about the tongue and sublingual veins.

In these inflammations in general, a slight diarrhoea relieves the patient, according to Arbuthnot. Therefore aliments which promote it are of service; such are tamarinds infused in whey, decoctions of farinaceous vegetables moderately acidulated, and such as abound with a cooling nitrous salt are useful. Burnet is said to be a specific in the quincy; mulberries, and all acids are beneficial. The mouth and throat must be kept moist, and the nose clear, that the air may have a free passage through it. Sydenham orders to bleed plentifully in the arm, and Boerhaave directs it to be by a large orifice. Afterwards a sublingual vein should be opened; but, according to Hoffman, bleeding in the jugular yields the best assistance. If the symptoms continue to be very urgent, the bleeding may be repeated in six or eight hours time, till they begin to be more mild. After the first bleeding, Sydenham orders a strong and large blister to be laid to the neck; then let the parts inflamed be touched with the following mixture. Take honey of roses, as much as you please; and mix it with as much spirit of sulphur as is sufficient to give it the greatest sharpness. Afterwards the following gargle is to be held in the mouth till it is hot; and is to be repeated pretty

often: take plantain-water, and frog-spawn, of each four ounces; red roses, four ounces; the whites of three eggs beat in water; and two drams of crystal sugar.

When the fauces are dry, hot, and the tongue swells, with difficulty of breathing and swallowing, Hoffman orders to take of the whites of eggs beat in water, two ounces; water of roses, one ounce; sal prunella, twelve grains; syrup of quinces, one ounce. Make a linctus, which is to be taken often; and let the neck be anointed as well behind as before with the following camphorated oil. Take of the oil of sweet almonds, one ounce; oil of white poppies, one dram; camphor, half a dram; after which let the patient take a cooling emulsion.

Boerhaave, after bleeding, orders a strong purge, and if that cannot be taken, a strong clyster. Emollient steams, or even the steam of hot water taken in at the mouth is beneficial. If the patient is not able to swallow any nourishment, take of good broth of flesh meat, ten ounces; nitre, ten grains; spirit of salt, six drops; make a clyster to be injected every eight hours, and retained as long as is possible. Hoffman says, that if the tumour tends to a suppuration, it is best promoted by holding dried figs in the mouth, and that when the tonsils are full of an inflammatory ichor, honey of roses mixt with the spirit of vitriol, and often applied to the part with a pencil, is excellent. In a latent internal exceeding hot quincy, the mouth must be frequently moistened with milk or cream, with an addition of sal prunella, and syrup of poppies.

Dr. Pringle observes, that the inflammatory quincy is the most frequent, as well as dangerous among soldiers, upon their first encampment; and that its tendency to bring on a suffocation, indicates the necessity of speedy and large bleedings, purging, and blistering. He also recommends the following application, as one of the most efficacious remedies in this terrible disorder: let a piece of thick flannel be moistened with equal parts of any common oil and of spirit of hartshorn, and applied to the throat, to be renewed once in four or five hours: this medicine, he tells us, he had from Dr. Young, physician at Edinburgh. By means of this application, the neck, and sometimes the whole body, is put into a sweat; which, after bleeding, either carries off or lessens the inflammation. He also tells us, that he has observed little benefit arising from gargles, and that the acid ones did more harm than good: however, a decoction of figs in milk and water, especially if the spirit of sal ammoniac be added, serves to thin the saliva, whereby the glands secrete more freely; a circumstance always conducive to the cure.

In the Philosophical Transactions, the jelly of black currants, swallowed down leisurely in small quantities, is asserted to be a specific for a quincy; and

# Q U O

and a decoction of the leaves or bark in milk, when the jelly cannot be had, used as a gargle, is said to cure all the inflammatory distempers of the throat that happen in the winter-time.

In malignant fevers, when there is an inflammation of the oesophagus, Hoffman orders to take nitre, one dram; camphor, three grains; sugar, one ounce; make a powder, which is to be given in an emulsion of sweet almonds, and may also be held in the mouth for some time before it is swallowed. That inflammatory pain which arises from a sharp salt serum in the glandulous parts of the fauces with redness and a copious flux of saliva, but without a fever, may be cured with a gargle of brandy alone. When there is a large defluxion of an impure serous humour upon the fauces, it requires a frequent use of gentle laxatives. When the symptoms of a quincy are so urgent, that the patient is in immediate danger of strangling, recourse must be had to bronchotomy, or opening of the wind-pipe.

**QUIRE** of *Paper*, the quantity of 24 or 25 sheets.

**QUIRISTER**, or **CHOIRISTER**, a person appointed to sing in the choir of a cathedral.

**QUIRK**, in building, a piece of ground taken out of any regular ground-plot, or floor: thus, if the ground-plot were oblong or square, a piece taken out of a corner to make a court or yard, &c. is called a quirk.

**QUISQUALIS**, in botany, a genus of plants, whose flower consists of five oblong, obtuse, patent petals, inserted in the chops of the cup, with ten bristly stamina: the fruit is a dry drupe, having five angles, and containing a roundish nut.

**QUIT-RENT**, in law, a small rent that is payable by the tenants of most manors, whereby the tenant goes quit and free from all other services; and it is said to be an acknowledgement, in token of subjection to the lord.

Antiently this payment was called white-rent, on account that it was paid in silver coin, and to distinguish it from rent-corn.

**QUITTER-BONE**, among farriers, the same with crotches. See **CROTCHES**.

**QUOIL**, or **COIL**, in the sea language, a rope or cable laid up round, one fack or turn over another, so that it may the more easily be stowed out of the way, and also run out free and smooth, without twistings or doublings.

**QUOIN**, or **COIN**, on board a ship, a wedge fastened on the deck, close to the breech of the car-

# Q U O

riage of a gun, to keep it firm up to the ship's side.

Cantic quoins are short three-legged quoins, put between calks to keep them steady.

**QUOINS**, in architecture, denote the corners of brick or stone walls.

The word is particularly used for the stones in the corners of brick buildings. When these stand out beyond the brick-work, their edges being chamfered off, they are called rustic quoins.

**QUORUM**, a word frequently mentioned in our statutes, and in commissions both of justices of the peace and others.

It is thus called from the words of the commission, *quorum A. B. unum esse volumus*. For an example, where a commission is directed to seven persons, or to any three of them, whereof A. B. and C. D. are to be two; in this case, they are said to be of the quorum, because the rest cannot proceed without them: so, a justice of the peace and quorum, is one without whom the rest of the justices in some cases cannot proceed.

**QUOTATION**, in literature, a citation or passage, rehearsed expressly in one author from another.

Quotations are usually distinguished by inverted commas.

**QUOTIDIAN**, *Quotidiana*, in medicine, an intermitting fever, or ague, the paroxysm or fit whereof returns every day.

This species of intermitent fevers is not so common as the tertian and quartan.

It attacks the patient early in the morning, with chillness and shivering; to which succeed a cardialgia, nausea, and inflation of the belly; in some, a pain in the head; in others, fainting fits; and in most, vomiting or stools, or both; after which comes on the hot fit, with thirst.

As to the cure, the best method seems to be first to attenuate the tough and vitiated humours in the stomach and intestines, by proper doses of vitriolated tartar, and the like; after which a gentle emetic, diaphoretics, and diluents, are to be administered; and, lastly, the bowels are to be strengthened by bitters and sub astringents; among which, the Peruvian bark claims a place, only to be used in smaller quantities than when trusted to alone for the cure.

**QUOTIENT**, in arithmetic, the number which arises by dividing the dividend by the divisor. See **DIVISION**.

# R.

## R A B

**R**, A liquid consonant, being the seventeenth letter of our alphabet. Its sound is formed by a guttural extrusion of the breath, vibrated through the mouth, with a sort of quivering motion of the tongue drawn from the teeth, and cannulated, with the tip a little elevated towards the palate.

In Greek words, it is frequently aspirated with an *h* after it, as in *rhapsody*, *rhetoric*, &c. otherwise it is always followed by a vowel at the beginning of words and syllables.

In the notes of the ancients, *R*. or *RO*. signifies *Roma*; *R.C.* *Romana civitas*; *R.G.C.* *rei gerendæ causa*; *R.F.E.D.* *recte factum & dictum*; *RG.F.* *regis filius*; *R.P.* *res publica*, or *Romani principes*; and *R.R.R.F.F.F.* *res Romana ruet ferro, fame, flamma*.

Used as a numeral, *R* anciently stood for 80, and with a dash over it, thus *R̄*, for 80,000; but the Greek *ρ*, or *ρ*, signified 100.

In the prescriptions of physicians, *R* or *R* stands for *recipe*, i.e. take.

**RABBETING**, in carpentry, the planning or cutting of channels or grooves in boards, &c.

In ship-carpentry, it signifies the letting in of the planks of the ship into the keel; which, in the rake and run of a ship, is hollowed away, that the planks may join closer.

**RABBI**, or **RABBINS**, a title which the Pharisees and doctors of the law, among the Jews, assumed, and literally signified masters or excellents.

There were several gradations before they arrived at the dignity of a rabbin, which was not conferred till they had acquired the profoundest knowledge of the law and the traditions. However, it does not appear that there was any fixed age; or previous examination necessary; but when a man had distinguished himself by his skill in the written and oral law, and passed through the subordinate degrees, he was saluted a rabbin by the public voice.

Among the modern Jews, for near seven hundred years past, the learned men retain no other title

## R A C

than that of rabbi, or rabbins: they have great respect paid them, have the first places or seats in their synagogues, determine all matters of controversy, and frequently pronounce upon civil affairs: they have even a power to excommunicate the disobedient.

**RABBINET**, a small piece of ordnance, between a falconet and a base. See the article **CANNON**.

**RABBINISTS**, among the modern Jews, an appellation given to the doctrine of the rabbins concerning traditions, in opposition to the caraites, who reject all traditions. See the article **CARAITES**.

**RABBIT**, *Cuniculus*, in zoology, a well known animal of the lepus or hare kind, with a very short tail.

The rabbit, though a smaller, is a handsomer creature than the hare, but is of various colours even in the same country; its general one, in this kingdom, being a pale brownish grey, on the back, and white on the belly; however, there are some darker, of a silvery grey, and altogether white.

There is also a long tailed species, of the size of the common rabbit, called the Siberian rabbit, from its being frequent in Russia and Tartary.

**RACEMUS**, among botanists, signifies a cluster or stalk, divided or branched into several footstalks, sustaining the flowers or fruits set together; such are the bunches of grapes, currants, &c. *racemus* anciently signifying a bunch of grapes.

**RACK**, **ARAC**, or **ARRAC**, in commerce, a spirituous liquor made by the Tartars of Tongusia, who are subject to the czarina of Muscovy.

This kind of rack is made of mare's milk, which is left to be sour, and afterwards distilled twice or thrice, between two earthen pots closely stopped, from whence the liquor runs through a small wooden pipe.

This liquor is more intoxicating than brandy distilled from wine.

**RACK**, is also a spirituous liquor which the English

lish get from Batavia or Malacca, of which there are three sorts; the one being extracted from the cocoa-tree, the second from rice, and the third from sugar; but the first is the best and most in use.

It is made of the blossom-bunch of the cocoa-tree; for which purpose, they tie the bunch while it is still wrapped up within its cod, or membrane, with a piece of packthread, and then with a knife make a cross cut in that bunch, a little above the place where it is tied, and adapt a pitcher to it to receive the liquor, which is called toddy, and is vinous, palatable, and sweet; others use a bamboecane, instead of a pitcher. Having thus drawn the liquor, they let it ferment, and afterwards distil it.

Goa and Batavia are the chief places for rack. At Goa there are several kinds; single, double, and triple distilled: but the double distilled, which is that commonly sent abroad, is but a weak spirit when compared with Batavia rack; yet, on account of its peculiar and agreeable flavour, it is preferred to all the other racks of India.

The prior rack, made at Madras, the Columbo and Quilone rack, being fiery hot spirits, are but little valued by the Europeans, and therefore seldom imported, though they are highly prized among the natives.

**RACKOON**, *Coati*, in zoology, an American quadruped of the shape of a beaver, only somewhat smaller, and with hair like that of a fox; its head too is like that of a fox, only that the ears are shorter, roundish, and naked; its tail is longer than its body, and not unlike that of a cat, with annular streaks of different colours.

**RADIAL CURVES**, are curves of the spiral kind, whose ordinates, if they may be so called, all terminate in the center of the including circle, appearing like radii of that circle; whence the name. See the articles **CURVE** and **SPIRAL**.

**RADIALIS**, or **RADIÆUS**, in anatomy, the name of two muscles of the arm; one of which, called *radialis internus*, is one of the three flexor muscles of the carpus, or hand, which arising from the internal condyle of the humerus, is inserted into the bone of the carpus next the thumb; and the other, called *radialis externus*, is one of the three extensor muscles of the hand, which arising from the external condyle of the humerus, is inserted into the first metacarpal bone.

**RADIANT**, or **RADIATING POINT**, in optics, is any point of a visible object from whence rays proceed.

**RADIATED FLOWERS**, in botany, are such as have several semi-florets set round the disc, in form of a radiant star; and are either ligulate, as in the aster; tubulose, as in the centaury; or naked, as in the artemisia.

**RADIATED**, is also used with respect to one of the ancient crowns. See the article **CROWN**.

**RADICAL**, in general, something that serves as a basis or foundation.

Hence physicians talk much of a radical moisture. See the article **MOISTURE**.

In grammar, we give the appellation radical to primitive words, in contradistinction to compounds and derivatives.

Algebraists also speak of the radical sign of quantities, which is the character expressing their roots. See **ROOT** and **CHARACTER**.

**RADICATION**, a term used by some for the action whereby plants take root, or shoot out roots. See the articles **ROOT** and **VEGETATION**.

**RADICLE**, that part of the seeds of all plants, which upon vegetating becomes its root, and is discoverable by the microscope. See the article **VEGETATION**.

**RADISH**, *Raphanus*, in botany, a genus of plants, whose flower is tetrapetalous and cruciform; the fruit is an oblong, smooth, spongy pod, having an acute point, swelling, and almost jointed, and containing several smooth roundish seeds.

There are several sorts of radishes, as the common purple-rooted radish, the salmon radish, the turnep-rooted radish, the black Spanish radish, &c. they are all propagated by sowing their seeds. The first and second sorts are cultivated in great quantities, for the supply of the London markets.

The seasons for sowing are various, according to the time they are intended for use. They are first sown at the beginning of the year, on moderate hot beds, having a sufficient depth of mould for their roots. In February they may be sown on warm well-sheltered borders; and in March, in more exposed situations, for the principal crop.

It is a common practice to sow them with other crops, as with carrots, spinach, &c. but it is much better to sow the radishes by themselves, and when come up, to hoe them out to the distance of about three inches; this will destroy the weeds, and encourage the roots to grow; and as they are soon fit for use, may be succeeded by French-beans, &c.

Radishes abound with a penetrating nitrous juice, which makes them diuretic, and cleansing to the intestines and viscera: they have somewhat also in their outward skin which is hot and biting, both which qualities help to make them a good antiscorbutic: they agree very well with most constitutions, provided they have good stomachs; and the juice is said to be good in the gravel, if four ounces of it be taken for four days in a morning fasting.

**Horse-RADISH**. See the article **HORSE-Radish**.  
**Water-RADISH**. See **SISYMBRIUM**.

**RADIUS**, in geometry, the semi-diameter of a circle, or a right-line drawn from the center to the circumference. See **CIRCLE**.

In trigonometry, the radius is termed the whole sine, or sine of 90°. See **SINE**.

**RADIUS**,

**RADIUS**, in anatomy, the exterior bone of the arm, descending along with the ulna from the elbow to the wrist.

In its upper extremity there is a glenoid cavity for its articulation with the humerus; also a crest, by means of which, it is articulated with the ulna: in the lower extremity the head is thicker, and of a more angular figure, with a very large hollow in the middle, for its articulation with the wrist.

**RADIX**, the same with root. See the article **Root**.

**RAFTERS**, in building, are pieces of timber, which standing by pairs on the reason or raising-piece, meet in an angle at the top, and form the roof of a building.

It is a rule in building, that no rafters should stand farther than twelve inches from one another: and as to their sizes or scantlings, it is provided by act of parliament, that principal rafters, from twelve feet six inches to fourteen feet six inches long, be five inches broad at the top, and eight at the bottom, and six inches thick. Those from fourteen feet six inches, to eighteen feet six inches long, to be nine inches broad at the foot, seven inches at the top, and seven inches thick: and those from eighteen feet six inches, to twenty-one feet six inches long, to be ten inches broad at the foot, eight at the top, and eight thick. Single rafters, eight feet in length, must have four inches and a half, and three inches three quarters in their square. Those of nine feet long must be five and four inches square.

Principal rafters should be nearly as thick at the bottom as the beam, and should diminish in their length one fifth, or one sixth of their breadth; the king-posts should be as thick as the principal rafters, and their breadth, according to the bigness of them that are intended to be let into them, the middle part being left somewhat broader than the thickness.

**RAGWORT**, *Jacobaea*, in botany, is comprehended by Linnæus with the *senecio*. See the article **SENECIO**.

**RAGOUT**, or **RAGOO**, a sauce, or seasoning, intended to rouse the appetite when lost or languishing.

This term is also used for any high seasoned dish prepared of flesh, fish, greens, or the like; by stewing them with bacon, salt, pepper, cloves, and the like ingredients.

**RAGULED**, or **ragged**, in heraldry, jagged or knotted. This term is applied to a cross formed of the trunks of two trees without their branches, of which they shew only the stumps.

**RAJA**, the title of the Indian black princes, the remains of those who ruled there before the moguls.

**RAJANIA**, in botany, a genus producing male and female flowers on different plants; the male flower has no corolla, but consists of a campanu-

lated cup, divided into six oblong acuminate parts, and contains six setaceous stamina, which are shorter than the cup; the female flower is apetalous, and contains three styles, crowned with obtuse stigmata: the fruit is roundish, and contains a single seed of the same form.

**RAIL**, in architecture, is used in different senses, as for those pieces of timber which lie horizontally between the pannels of wainscot; for those which lie over and under the balusters in balconies, stair-cases, and the like; and also for those pieces of timber which lie horizontally from post to post in fences, either with poles or without.

**RAIL**, *Ortygometra*, in ornithology, a genus of birds of the order of the scolopaces, the beak of which is shorter than the toes: it is of a compressed form, and terminated in a point; but the two chaps are equal in length.

It is of the size of the common magpye, and is an elegant bird, of a bright brown colour, variegated with black spots: it is common in rich pastures, where its common note is *crex, crex*.

**RAIN**, a watery-meteor, which descends from the clouds in form of drops of water.

Rain is apparently the precipitated vapours of watery clouds: thus, when various congeries of clouds are driven together by the agitation of the winds, they mix and run into one body, and by that means dissolve and condense each other into their former substance of water; also the coldness of the air is a great means to collect, compact, and condense clouds into water; which being heavier than the air, must of necessity fall through it in the form we call rain. Now the reason why it falls in drops, and not in whole quantities, as it becomes condensed, is the resistance of the air; whereby, being broken and divided into smaller and smaller parts, the farther it passes through the air, it at last arrives to us in small drops.

Mr. Derham accounts for the precipitation hence, that the vesiculæ being full of air, when they meet with a colder air than they contain, their air is contracted into a less space; and, consequently, the watery shell rendered thicker, so as to become heavier than the air, &c.

Others only allow the cold a part in the action, and bring in the winds as sharers with it: indeed, it is plain, that a wind, blowing against a cloud, will drive its vesiculæ upon one another, by which means several of them coalescing, will be enabled to descend; and the effect will be still more considerable if two opposite winds blow towards the same place. Add to this, that clouds already formed, happening to be aggravated by fresh accessions of vapour continually ascending, may thence be enabled to descend.

According to Rohault, the great cause of rain is the heat of the air, which after continuing for sometime near the earth, is at length carried up on high.

high by a wind, and there thawing the snowy villi, or flocks of the half frozen vesiculæ, reduces them into drops; which, coalescing, descend.

Others, as Dr. Clarke, &c. ascribe this descent of the clouds rather to an alteration of the atmosphere than of the vesiculæ; and suppose it to arise from a diminution of the elastic force of the air. This elasticity, which depends chiefly or wholly on the terrene exhalations, being weakened, the atmosphere sinks under its burden, and the clouds fall.

Now the little vesicles being once upon the descent, will persist therein, notwithstanding the increase of resistance they every moment meet with. For as they all tend toward the center of the earth, the farther they fall, the more coalitions will they make; and the more coalitions, the more matter will there be under the same surface; the surface only increasing as the squares, but the solidity as the cube; and the more matter under the same surface, the less resistance there will be to the same matter. Thus, if the cold, wind, &c. act early enough to precipitate the ascending vesicles, before they are arrived at any considerable height, the coalitions being but few, the drops will be proportionably small; and thus is formed a dew. If the vapours be more copious, and rise a little higher, we have a mist or fog. A little higher still, and they produce a small rain, &c. If they neither meet with cold nor wind, they form a heavy, thick, dark sky.

Hence many of the phenomena of the weather may be accounted for: as, why a cold summer is always a wet one, and a warm a dry one; Why we have commonly most rain about the equinoxes; Why a settled, thick, close sky, scarce ever rains till it have been first clear; As to the quantity of rain that falls, its proportion in several places at the same time, and in the same place at several times, we have store of observations, journals, &c. in the Memoirs of the French academy, Philosophical Transactions, &c.

**RAIN-BOW**, *Iris*, in meteorology, a meteor, in form of a party-coloured arch, or semi-circle, exhibited in a rainy sky, opposite to the sun, by the refraction of his rays in the drops of falling rain. See the article REFRACTION.

In order to illustrate this phenomenon, suppose BNFG (plate LXXXVIII. fig. 1.) to be a spherical drop of falling rain, and AN a ray of the sun falling upon it in the point N; which ray suppose refracted to F, from thence reflected to G, and there again refracted in the direction GR to the eye of a spectator; and let IG be perpendicular to the drop in the point G; then will the ray or beam of light, by its refraction at G, be separated into several sorts of rays, which will paint their respective colours in that part of the drop; of which that next the perpendicular IG will be red, as being least refracted; and the rest in order above it, viz. orange, yellow, green, blue, indigo, violet. Now it is found by computation, that the greatest angle

SEO, (fig. 2.) or EOP, because OP parallel to SE, under which the most refrangible rays can come to the eye of the spectator at O, is  $40^{\circ} 17'$ ; and that the great angle FOP, under which the most refrangible rays come to the eye at O, is  $42^{\circ} 2'$ : and so all the particles of water, within the difference of those two angles, EF, will exhibit severally the various colours of the prism, and constitute the interior rain-bow in the cloud. See COLOUR.

If the beam of light go not out of the drop, at G, but is reflected a second time, to H; (fig. 1 and 2) and is there refracted in the direction HS, making the angle SYA with the incident ray AN, it will paint on the part H the several colours of light; but in an inverse order to the former, and more faint, by reason of the rays lost by the second reflection. It has been found also, that the least angle SGO, or GOP, under which the least refrangible rays can come to the eye at O, after two reflections and two refractions, is  $50^{\circ} 57'$ ; and the least angle HOP, under which the most refrangible rays can come to the eye in this case, is  $54^{\circ} 7'$ : whence all the colours of the exterior rain-bow, will be formed in the drops from G to H, which is the breadth of this bow, viz.  $3^{\circ} 10'$ ; whereas the breadth of the former, or interior bow, viz. EF, is but  $1^{\circ} 45'$ ; and the distance between the bows, viz. FG, is  $8^{\circ} 55'$ . And such would be the measure of the bows, were the sun but a point; but since his body subtends an angle of half a degree, it is evident, by so much will each bow be increased, and the distance diminished.

To apprehend rightly the different affections of the rainbow, we must attend to the following particulars. 1. That though the rain-bow be occasioned by the refracted and reflected light of the sun falling on the drops of rain, yet neither of them is produced by any rays falling on any part of the drop indifferently, but by those only which fall on the surface of the drop BLQG (fig. 1, 2, 3.) in or about the point N, as the ray AN; those which fall nearer to B, or farther towards L, being unconcerned in this production. 2. The internal bow is produced by two refractions and one reflection. The first refraction is of the incident rays extremely near AN, by which they proceed from N to one common point or focus at F, from whence they are reflected to G, and are there a second time refracted towards R, and produce the various colours of the said bow. 3. There is a necessity that several rays should be refracted together to the point F, that being reflected together from thence to G they may there go out parallel, and so come in quantity sufficient to excite the sensation of colours in a strong and lively manner. Now those rays, and those only, which are incident on the globule about the point N, can do this, as will appear from what follows: for, 4. The point F makes the arch QF a maximum, or the distance QF from the axis of

Fig. 7. The Plain Scale.

|    |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     | of the drop  $SQ$  is greater than any other distance from whence any other rays nearer to the axis, as  $SD$ ,  $SE$ , or farther from it, as  $SH$ ,  $SI$ , are reflected; because those which are nearer after the first refraction tend to points in the axis produced more remote than that to which the ray  $SN$  tends; and therefore as their distance from the axis increases, so likewise will the distances of their points of reflection  $QP$ ,  $QO$ , till the ray becomes  $SN$ ; after which the rays more remote from the axis, as  $SH$ ,  $SI$ , are refracted towards the points,  $XY$ , which are nearer and nearer to the axis; and this occasions the points of reflection on the farthest side of the drop to decrease again from  $F$  towards  $Q$ . Hence it will necessarily happen, that some rays above and below the ray  $SN$  will fall upon the same point, as  $O$  or  $P$ , on the farthest side; and for that reason they will be so reflected from thence as to go out of the drop by refraction parallel to each other. Thus let  $SE$  below, and  $SH$  above the ray  $SN$  be refracted both to one point  $O$ ; from hence they will be reflected to  $M$  and  $L$ , and will there emerge parallel, it is true, but alone; being divested of their intermediate rays  $SN$ , which going to a different point  $F$  will be reflected in a different direction to  $G$ , and emerge on one side, and not between those rays, as when they were incident on the drop. All which is evident from the figure. 6. As this will be the case of all the rays which are not indefinitely near to  $SN$ , it is plain that being deprived of the intermediate rays, their density will be so far diminished, as to render them ineffectual for exciting the sensation of colours; and they are therefore called inefficacious rays, in contradistinction to those which enter the drop near  $SN$ , and which, having the same point  $F$  of reflection, are not scattered like the others, but emerge together at  $G$ , so as to constitute a beam  $GR$  of the same density with the incident beam  $SN$ , and therefore capable of exhibiting a vivid appearance of colours, and for this reason are called efficacious rays.

*Phænomena of the RAINBOW.* The first is, that each is variegated with all the prismatic colours. This is a necessary consequence of the different refrangibility of the rays refracted and reflected in drops of falling rain. Let  $A$  (fig. 4.) be such a drop,  $SN$  a ray entering it at  $N$ , which is refracted to  $F$ , from whence refracted to  $G$ , where, as it emerges, it is refracted into all the several sorts of rays of which it is composed, viz.  $GR$ , the least refrangible or red-making ray,  $GO$  the orange,  $GY$  the yellow,  $GG$  the green,  $GB$  the blue,  $GI$  the indigo, and  $GV$  the violet, or most refrangible ray.

The truth of this may be easily proved by experiment, by suspending a glass globe filled with water in the sun-shine, and viewing it in such a position, that the rays  $SN$  will fall upon it, and emerge to the eye at  $A$ , under the several angles from  $SFR$  to

$SFV$ ; which may be easily effected by letting the globe descend from  $A$  to  $G$ , by a string going over a pulley.

Hence, the second phænomenon, viz. the circular form, is accounted for, and also the third, which is the breadth of the bow; for that will be equal to the angle  $ARG = RGV = 1^\circ 45'$ , where the ray, as here, emerges after one reflection. These particulars are represented more completely in fig. 5. where  $BGD$  is the red circumference formed by the rotation of the ray  $AG$ , that can first come to the eye at  $A$ ; and  $CgE$  is the violet arch formed by the least refrangible ray  $gA$ ; after which the rays are all refracted below the eye. And thus, by the intermediate rays and colours, the whole interior bow is produced.

The fourth phænomenon is the appearance of two bows. This follows from hence, that after an efficacious ray of light  $SN$ , entering a drop of rain, has been twice reflected on the farthest side at  $F$  and  $H$ , it will emerge refracted into all its simple or constituent rays at  $G$  upon the upper side of the drop, so as to make with the incident ray the angle  $GYN = SYA = 54^\circ 10'$ , if that ray be the violet sort, or most refrangible; but if it be of the red or least-refrangible sort, then the said angle is but  $50^\circ 58' = SyA$ .

Therefore all those drops which are so situated around the eye, that their most refrangible rays shall fall upon it, must with those rays make an angle with the the line  $AP$  passing through the eye parallel to the sun's rays, viz. the angle  $GAP$ , equal to the angle  $SYA$ , or  $GAP = 54^\circ 10'$ . These rays, therefore will every where exhibit a violet colour in the arch  $PGL$ . For the same reason, those drops whose least refrangible rays fall upon the eye at  $A$ , make the angle  $gAP = 50^\circ 58'$ ; and so the ray  $Ag$ , revolving about the axis  $AQ$ , will describe the circular arch  $MgK$ , which will exhibit the deepest red; and all the drops between  $G$  and  $g$  will paint the several other coloured peripheries, all which together will complete the exterior bow.

The fifth phænomenon is the greater breadth of the exterior bow. Thus, if from  $54^\circ 10'$  we subtract  $50^\circ 58'$ , we shall have  $3^\circ 12' = Gg$  the width of the outer bow; which, therefore is almost twice as wide as the interior bow.

The sixth phænomenon is the distance between the two bows, which is thus determined: from the angle which the least refrangible ray in the upper bow makes with the axis  $AP$ , viz.  $50^\circ 58'$ , subtract the angle  $42^\circ 2'$  which the most refrangible rays make therewith in the lower bow, and the remainder  $8^\circ 56' = gAF$  is the arch of distance between the bows.

The seventh phænomenon is the inverse order of the colours in the two bows. This follows from the contrary parts of the drop on which the ray is incident

incident, and from whence it emerges and is refracted. Thus, because the rays SN enter the upper part of the drop, and emerge from the lower, it is evident the rays refracted in this case (viz. in the interior bow) will have a situation quite the reverse of those which enter on the lower part of the drop, and are refracted from the upper, as in the exterior bow, whose colours are violet, indigo, blue, green, yellow, orange, and red; whilst those of the other are red, orange, yellow, green, blue, indigo, and violet; counting from the upper parts downwards in both.

The eighth phenomenon is the faintness of the exterior bow, in comparison of the interior one. This is the consequence of the rays being twice reflected within the drops which form the outer bow, They who make the experiment in a dark chamber, may wonder when they observe how large a part of the beam (that enters the globule at N) goes out at F, that there should be enough in the remaining part FG to exhibit the colours so strong and vivid in the first bow as they appear; but then, considering how much of this residual ray is refracted at G, it is rather a wonder how the very small part reflected to H, should there when refracted, be in quantity sufficient to excite any distinct ideas of colours at all.

The ninth phenomenon is, that sometimes more than two bows appear; as in a very black cloud we have observed four and a faint appearance of a fifth: but this happens rarely. Now, these spurious bows as we may call them, cannot be formed in the manner as the two principal bows are, that is, by refraction after a third, fourth, fifth, &c. refraction; for the beam is by much too weak to exhibit colours by refraction even after the third reflection only, much less would it after a fourth or fifth. Besides, though after a third and fourth reflection of the rays they should be supposed capable of shewing their colours, yet the bows made thereby would not appear at the same time with the other two, nor in the same part of the heavens, but in the rain between us and the sun, and must be viewed by the spectator's face turned towards the sun and not from it, as in the other case.

The tenth phenomenon, is the appearance of the bows in that part of the heavens opposite to the sun. This necessarily happens from the incident and emergent ray being both on one side of the drop; for it is evident, that in order to see the colours, we must look to that part against which the sun shines.

The eleventh phenomenon is, that they never appear but when and where it rains. This is because rain affords a sufficient plenty of drops, or aqueous spherules, proper to reflect and refract the light fit for this purpose, which cannot be done without a requisite size, figure, and disposition of the particle, which the vapour of the cloud does

not admit, and therefore clouds alone exhibit no such appearance.

The twelfth phenomenon is the dimension of the bows. This is determined easily; for continuing the axis AP to Q, the center of the bows, we have the semidiameter of each bow in the angle QAg or QAG; the double of which gives the angles which the whole diameters of the bows subtend, and are therefore the measure of their magnitude. The thirteenth phenomenon is the altitude of the bow above the horizon, or surface of the earth. This is equal to the angle GAT, which may be taken by a quadrant, or it may be known for any time by having given the sun's altitude, which is equal to the angle TAQ; which therefore subtracted from the constant angles QAF, or QAY, will always leave the angle of the apparent height of the bow.

**Lunar RAINBOW.** The moon sometimes also exhibits the phenomenon of an iris, by the refraction of her rays in drops of rain in the night-time.

Aristotle says, he was the first that ever observed it; and adds, that it is never visible, but at the time of full moon.

The lunar iris has all the colours of the solar, only fainter.

**Marine RAINBOW,** the sea-bow, is a phenomenon sometimes observed in a much agitated sea, when the wind sweeping part of the tops of the waves, carries them aloft; so that the rays of the sun are refracted, &c. as in a common shower.

**RAISER,** in building, a board set on edge under the fore side of a step, stair, &c.

**RAISING-PIECES,** or **REASON-PIECES,** in architecture, are pieces that lie under the beams, and over the posts or puncheons.

**RAISINS,** grapes prepared by suffering them to remain on the vine till they are perfectly ripe, and then drying them in the sun, or by the heat of an oven. The difference between raisins dried in the sun, and those dried in ovens, is very obvious: the former are sweet and pleasant, but the latter have a latent acidity with the sweetness that renders them much less agreeable.

The common way of drying grapes for raisins, is to tie two or three bunches of them together while yet on the vine, and dip them into a hot lixivium of wood ashes with a little of the oil of olives in it. This disposes them to shrink and wrinkle, and after this they are left on the vine three or four days separated on sticks in an horizontal situation, and then dried in the sun at leisure, after being cut from the tree. The finest and best raisins are those called in some places Damascus and Jube raisins; which are distinguished from the others by their size and figures: these are flat and wrinkled on the surface, soft and juicy within, and near an inch long, and when fresh and growing on the bunch, are of the size and shape of a large olive.

The

The raisins of the sun and jar-raisins, are all dried by the heat of the sun, and these are the sorts used in medicine. However, all the kinds have much the same virtues; they are all nutritive and balsamic; they are allowed to be attenuant, are said to be good in nephritic complaints, and are an ingredient in pectoral decoctions, in which cases, as also in all others where astringency is not required of them, they should have the stones carefully taken out.

**RAITING**, or **RATING**, the laying of flax, hemp, timber, &c. when green, in a pond or running water, to season and prepare it for future uses.

**RAKE** of a ship is all that part of her hull which hangs over both ends of her keel. That which is before, is called the fore-rake, or rake-forward; and that part which is at the setting on of the stern-post, is called the rake-aft, or afterward.

**RAKE** of the rudder, is the hindermost part of it.

**RAKING-TABLE**, or **RAKED-TABLE**, among architects, is a member hollowed in the square of a pedestal, &c.

**RALLYING**, in a war, re-assembling or calling together troops broken and put to flight.

**RAM**, in zoology, the male of the sheep kind. See the article **SHEEP**.

**RAM**, in astronomy, the same with Aries. See the article **ARIES**.

**Battering RAM**, in antiquity, a military engine used to batter and beat down the walls of places besieged.

The battering ram was of two sorts, the one rude and plain the other compound. The former seems to have been no more than a great beam which the soldiers bore on their arms and shoulders, and with one end of it by main force assailed the wall. The compound ram is thus described by Josephus: it is a vast beam, like the mast of a ship, strengthened at one end with a head of iron, something resembling that of a ram, whence it took its name. This was hung by the middle with ropes to another beam, which lay across two posts; and hanging thus equally ballanced, it was by a great number of men drawn backwards and pushed forwards, striking the wall with its iron head.

Plutarch informs us, that Mark Anthony, in the Parthian war, made use of a ram fourscore feet long: and Vitruvius tells us, that they were sometimes an hundred and six, and sometimes an hundred and twenty feet in length; and to this perhaps the force and strength of the engine was in a great measure owing. The ram was managed at one time by a whole century of soldiers, and they being spent, were seconded by another century, so that it played continually without any intermission.

**RAM'S-HEAD**, in a ship, is a great block belonging to the fore and main-halliards. It has three

flivers in it; into which the halliards are put, and in a hole at the end of it are reeved the ties.

**RAMADAN**, a solemn season of fasting among the Mahometans, kept in the ninth month of the Arabic year. This fast consists in abstaining from meat and drink, and from lying with their wives each day, from the rising of the sun till the stars appear; and is of such strict obligation, that none is excused from it; for the sick, and all others who cannot observe it in this month, are obliged to fast another entire month instead of it. So superstitious are the Mahometans in the observance of this lent, that they dare not wash their mouths, or even swallow their spittle. The men are, indeed, allowed to bathe themselves, on condition they do not plunge the head under water, lest some drops enter by the mouth or ears, &c. but as for the women, they are strictly forbid bathing, for fear of taking in water at the pudendum. However they frequently feast all night. The Mahometans call this month holy, and believe that as long as it lasts, the gates of paradise are open, and those of hell shut.

**RAMAGE**, the boughs or branches of trees.

**RAMIFICATION**, the production of boughs or branches, or of figures resembling branches.

**RAMMER**, an instrument used for driving down stones or piles into the ground; or for beating the earth, in order to render it more solid for a foundation.

**RAMMER** of a Gun, the gun-stick; a rod used in charging of a gun, to drive home the powder, as also the shot and the wad, which keeps the shot from rolling out. The rammer of a great gun is used for the same purpose. It has a round piece of wood at one end, and the other is usually rolled in a piece of sheep-skin, fitted to the bore of the piece, and is used to clear her after she has been discharged, which is called spunging the piece.

**RAMPANT**, in heraldry, a term applied to a lion, leopard, or other beast that stands on his hind-legs, and rears up his fore feet in the posture of climbing, shewing only half his face, as one eye, &c. It is different from saliant, in which the beast seems springing forward, as if making a sally.

**RAMPART**, in fortification, is an elevation of earth round a place capable of resisting the cannon of an enemy; and formed into bastions, curtains, &c.

A rampart ought to be sloped on both sides, and to be broad enough to allow room for the marching of waggons and cannon, beside that allowed for the parapet, which is raised on it: its thickness is generally about ten or twelve fathom, and its height not above three, which is sufficient to cover the houses from the battery of the cannon. The rampart is encompassed with a ditch, and is sometimes lined or fortified on the inside, otherwise it has a berme. See the article **BERME**.

Upon

Upon the rampart soldiers continually keep guard, and pieces of artillery are planted there for the defence of the place.

**RAMPART**, in civil architecture, is used for the space left between the wall of a city, and the next houses.

**RAMPION**, in botany. See the article **PHYTEUMA**.

**RANCID**, denotes a fatty substance that is become rank or musty; or has contracted an ill smell by being kept close.

**RANDIA**, in botany, an evergreen shrub, rising to the height of ten or twelve feet, and covered with a whitish bark; the branches come out opposite from the side of the stalk, each pair crossing the other. The leaves are of a thick consistence, about an inch long, and three quarters broad, a little indented at the top, and placed by pairs standing on short footstalks; at the joints immediately under the leaves, are produced two short spines standing opposite. The flowers are produced from the side of the branches, they each are small, white, and tubulose, with the limb divided slightly into five parts, and contain five short filaments, topped with oblong antheræ. The fruit is an oval berry, having a brittle shell under a thin skin, containing one cell, which incloses many compressed, orbiculated, cartilaginous seeds, surrounded with a black pulp. This plant is propagated by seeds, but, being a native of the West-Indies, it requires a hot-house to preserve it in this climate.

**RANDOM SHOT**, in gunnery, is a shot made when the muzzle of a gun is raised above the horizontal line, and is not designed to shoot directly, or point-blank.

The utmost random of any piece is about ten times as far as the bullet will go point-blank. The bullet will go farthest when the piece is mounted to about  $45^\circ$  above the level range. See the article **GUNNERY**.

**RANGE**, in gunnery, the path of a bullet, or the line it describes from the mouth of the piece to the point where it lodges. If the piece lie in a line parallel to the horizon, it is called the right or level range: if it be mounted to  $45^\circ$  it is said to have the utmost range, all others being 00 and  $45^\circ$  are called the intermediate ranges.

**RANGER**, a sworn officer of a forest, appointed by the king's letters patent, whose business is to walk through his charge, to drive back the deer out of the purlieus, &c. and to prevent all trespasses within his jurisdiction at the next forest-court.

**RANGES**, in a ship, two pieces of timber that go across from side to side; the one on the fore-castle, a little abaft the foremast, and the other in the beak-head, before the wouldings of the bowsprit.

**RANGING**, in war, disposing the troops in the order proper for an engagement, or for marching.

**RANGING**, in building, signifies running strait, when the sides of a work do not break into angles.

**RANK**, the order or place allotted a person, suitable to his quality or merit.

**RANK**, in war, is a row of soldiers, placed side by side.

**RANSOM**, a sum of money paid for the redemption of a slave, or for the liberty of a prisoner of war.

In our law-books, ransom is also used for a sum paid for the pardon of some great offence, and to obtain the offender's liberty.

**RANT**, in the drama, an extravagant, unnatural, and improbable flight of passion.

**RANULA**, or **RANA**, in medicine, a tumour under the tongue, which, like a ligature, hinders a child from speaking or sucking.

The matter contained in these tumours is various, it being sometimes a tenacious and mucous lymph, sometimes a thick and purulent matter, and sometimes of a hard and stony consistence.

The safest method of cure, according to Heister, is to turn the tongue upwards, and to make a transverse incision through the tumour, in order to discharge the included matter; after which you may deterge or destroy the remaining tunic with honey of roses sharpened with spirits of vitriol, and then the cure may be easily completed with a mixture of oil and sugar. Sometimes the tubercle breaks of itself, and then you must deterge and heal the ulcer as before.

**RANUNCULUS**, crowfoot, in botany, a genus of plants, whose flower consists of five obtuse petals with small ungues, each having an open nectarium above the claws; the filaments are numerous, about half the length of the petals, and terminated by erect, oblong, obtuse, twin antheræ: there is no pericarpium; but the seeds, which are irregular and numerous, are connected to the receptacle by very short peduncles.

Botanists enumerate divers species belonging to this genus, but the oriental sorts are most admired and cultivated in our gardens, as few flowers equal them, either in richness of colour, or for the variety and beautiful mixture of their tints. They are natives of Turkey, Arabia, and Persia, from whence they have been imported into Europe.

A good ranunculus may be distinguished by the following properties: 1. The stalk or stem, straight, erect, strong, well proportioned, and surmounted by a flower, well disposed and standing evenly. 2. The flower large, well turned, full like a rose, and the petals cupping or bending into a semicircle. 3. The petals bright, thick, and large enough to hide the style. 4. The colours with which the petals are distinguished, should be disposed in even, straight, and distinct lines, without mixing or running into each other. The particular colours that most set off a flower, are an agreeable mixture of gold

gold and ruby, or brown; stripes of violet, or tyrian; purple or white, edged with vermilion, blue, or black. If all these properties meet in a ranunculus, it may then be pronounced a perfect flower; but as this perfection is rather to be wished for than expected; and as a ranunculus that has two or three of these properties, may be reckoned a fine flower, it may therefore be worthy the esteem of the curious.

This beautiful flower is either increased by off-sets from the roots, or by sowing its seeds: the best soil for the ranunculus, is a good rich loam, not very strong, taken from the surface of a common, and well mixed with cow-dung, at least a year before it is wanted; the depth which this should be laid in beds, where they are intended to blow, should be about three feet deep, which should be elevated six or eight inches above the common surface, if the place is naturally wet, otherwise the fibres would rot.

When the earth in the beds is settled, and the season for planting is come, which is from the middle of October to the latter end of November, the roots should be placed about two inches in depth, observing to place them with their crowns upright, and at about six inches asunder, and afterwards levelling the surface of the earth. In December, the buds will appear above-ground, when a sprinkling of fresh earth over the beds will be of service; and they should be arched over with hoops covered with mats in bad weather. In the spring, the flower-stems will appear, when the earth between the plants should be stirred, which will destroy the weeds and strengthen the bloom.

When the flowers and leaves are decayed, the roots should be taken up and cleaned of the earth which may adhere to them, and after being dried in the shade, they should be reserved in a dry room till the following autumn, which is the season for planting them again.

Those curious florists who are desirous of new varieties, endeavour to do so by saving seed from those ranunculuses which are semi-double, those that are very double rarely producing any; for this purpose, such semi-double ones should be pitched upon as have the finest and brightest colours: being prepared with the seed, the season for sowing it is in the spring or August, the latter season is to be preferred; for if they are well protected from the rains and frosts, they will be much stronger than those sown in the spring; after which, all the trouble will be to keep the pots or boxes of seedlings well watered, and when the leaves decay, the roots are to be taken up, and preserved till the season for planting, when they may be treated as before-directed for the old roots. The next year the florist will reap the fruits of his labour, his new flowers will then appear, and, in all probability, fully gratify his curiosity with their beauty; and by this method of sow-

ing the seeds every year, he will not only encrease his stock of roots, but also raise new beauties, which may be greatly mended by changing the seeds into fresh ground; it will also be necessary to take away all the earth out of the beds, in which the roots were blown the preceding year, and put in fresh, if it is intended that the ranunculuses are to be planted there again, otherwise they will not thrive near so well.

To this genus of ranunculus, Linnæus has added the *ficaria* of Dillenius, and the *ranunculoides* of Vaillant.

**RAPA**, the turnep, in botany. See the article **TURNEP**.

**RAPE**, a species of *brassica*, or cabbage, described by authors under the name of the *napus sylvestris* and *bunius sylvestris*.

This plant is much cultivated for feeding cattle in several counties of England. The season for sowing is about the middle of June, and the plants afterwards should be hoed out as practised with turneps, with the difference only of leaving them much nearer together.

As this plant is so hardy as not to be destroyed by frost, it is of great service in hard winters for feeding sheep; for when the ground is so hard frozen as that the turneps cannot be taken up, these plants may be cut off for a supply: they will also afford late food, after the turneps are run to seed; and if it is afterwards permitted to stand for seed, it will pay extremely well, for from the seed is drawn an oil, called rape-oil, which is used in the woollen manufactures, and, in the materia medica, is esteemed attenuant, cordial, and sudorific.

**RAPE**, in law, the having carnal knowledge of a woman by force and against her will.

**RAPE of the Forest**, a trespass committed in a forest by violence.

**RAPE**, is also a name given to the division of a county, and sometimes means the same as a hundred, and at other times signifies a division consisting of several hundreds; thus Suffex is divided into six rapes, every one of which, besides its hundreds, has a castle, a river, and a forest, belonging to it.

The like parts in other counties are called tithings, lathes, or wapentakes.

**RAPE**, also signifies the stalks of the clusters of grapes, when dried and freed from the fruit. This is used in making vinegar.

**RAPHANUS**, the radish, in botany. See the article **RADISH**.

**RAPIER**, formerly signified a long, old-fashioned, broad sword, such as those worn by the common soldiers; but it now denotes a small sword, as contradistinguished from a back-sword.

**RAPINE**, in law, taking away another's goods, &c. openly and by violence.

**RAPISTRUM**, in botany, the same with *crambe*. See the article **CRAMBE**.

## R A R

**RAPTURE**, an extasy or transport of mind. See **EXTASY**, **ENTHUSIASM**, &c.

**RAPUNTUM**, the cardinal-flower, in botany, a genus of plants, whose flower is monopetalous and slightly ringent; the tube is long, cylindrical, and a little curved; the limb is cut into five segments, two of which form the upper lip, and are less than the three lower ones, which compose the under lip: the stamina are five subulated filaments, the length of the tube, topped with oblong antheræ, joined in a cylindrical form at top, but opening in five parts at their base: the fruit is an oval capsule, opening at top, and contains many very small seeds.

**RAREFACTION**, *Rarefactio*, in physics, the act whereby a body is rendered rare; that is, brought to possess more room, or appear under a larger bulk without accession of any new matter.

Rarefaction is most properly restrained to that expansion of a mass into a larger bulk, which is effected by heat. All expansion from other causes they call dilatation.

It is by rarefaction that gun-powder has its effect, and to the same principle also we owe our æolipiles, thermometers, &c.

The degree to which the air is rarifiable, exceeds all imagination; such is the rarefaction of common air from its own principle of elasticity, and without any previous condensation, that Mr. Boyle found it to dilate itself so as to take up 13679 times its former space; and when compressed, the same author found its greatest space when most rarified, to its least when most condensed, as 550000 to 1.

Such an immense rarefaction, Sir Isaac Newton shews, is inconceivable on any other principle than that of a repelling force inherent in the air, whereby its particles mutually fly from one another.

This repelling force, he observes, is much more considerable in air than in other bodies, as being generated from the most fixed bodies, and that with much difficulty, and scarce without fermentation; those principles being always found to fly each other with the most force, which, when in contact, cohere the most firmly. M. Mariotte established this as a principle, from experiments, that the different rarefactions or condensations of the air, follow the proportion of the weights wherewith it is pressed. Hence, supposing the mercury in the level of the sea suspended to 28 inches, which is the weight of the whole atmosphere; and that 60 feet height of air are equivalent to a line or  $\frac{1}{12}$  of an inch of mercury; so that the barometer, at the height of 60 feet from the sea, would fall a line.

It is easy finding what height of air would be equal to a second, or any other line of mercury; for, as 28 inches of mercury  $\frac{1}{12}$  are to 28 inches, so is the height of 60 feet of air to a fourth term, which is the height of air corresponding to a second line of mercury. And after the same manner,

## R A T

may the height of air corresponding to each line be found, which will make a geometrical progression, the sum whereof will be the whole height of the atmosphere, and of consequence a certain part of that sum will be the height of a mountain, at whose top the barometer shall have sunk a certain quantity.

**RAREFACTIVES**, in medicine, remedies that open and enlarge the pores of the skin, to give an easy vent to the matter of perspiration: or such medicines as rarify the blood, as anise, mallows, pellitory, chamomile-flowers, linseed, &c.

**RASANT**, or **RAZANT**, in fortification. Rasant-flank, or line, is that part of the curtain or flank whence the shot exploded rase, or glance, along the surface of the opposite bastion.

**RASH**, in medicine, an eruption upon the skin, thrown out in fevers or surfeits.

**RASP**, a rank fort of file. See the article **FILE**.

**RASPBERRY-BUSH**, in botany, a species of rubus; the root is perennial, and divided into several branches, from which arise several annual stalks, about six feet high, armed with thorns: the leaves are like those of the bramble, but more tender and soft, of a brownish green above, but whitish underneath: the flowers are white, and consist of five petals, disposed in the form of a rose; and the cup is divided into five parts, from the center of which the pistil arises, surrounded with many stamina, which is afterwards succeeded by a well-known fruit, of a white or red colour.

The raspberry is commonly propagated by suckers, which should be planted about two feet asunder in the rows, and five feet row from row; they like a good strong fresh soil. In autumn, those shoots which produced the fruit will decay, when they should be taken off, and a few of the strongest young shoots preserved, for bearing the succeeding year; cutting out all those that are weak, and digging between the rows in winter, which is all the management they require.

**RAT**, in zoology, the English name of several species of the mus-kind; as the common-rat, the ground-rat, and the water-rat.

**RAT-TAILS**, or **ARRESTS**, in the manege, signify hard callous swellings upon the hinder legs, under the hough running along, the finew.

A horse is called rat-tail when he has no hair upon his tail.

**RATAFIA**, a fine spirituous liquor, prepared from the kernels, &c. of several kinds of fruit, particularly of cherries, and apricots.

**RATCH**, or **RASH**, in clock-work, a sort of wheel having twelve fangs which serve to lift up the detents every hour, and make the clock strike. See **CLOCK**.

**RATCHETS**, in a watch, are the small teeth at the bottom of the fusee, or barrel, which stops it in winding up.

**RATE**,

# R A T

**RATE**, a standard or proportion, by which either the quantity or value of a thing is adjusted.

**RATE** of a ship of war, is its order, degree, or distinction, as to magnitude, burden, &c. The rate is usually accounted by the length and breadth of the gun deck, the number of tons, and the number of men and guns the vessel carries. Of these there are six rates. A first rate man of war has its gun-deck from 159 to 174 feet in length, and from 44 to 50 feet broad; it contains from 1313 to 1882 tons, has from 706 to 800 men, and carries from 96 to 100 guns. Second rate ships have their gun-decks from 153 to 165 feet long, and from 41 to 46 broad; they contain from 1086 to 1482 tons, and carry from 524 to 640 men, and from 84 to 90 guns. Third rates have their gun-decks from 140 to 158 feet in length, from 37 to 42 feet broad; they contain from 871 to 1262 tons; carry from 389 to 476 men, and from 64 to 80 guns. Fourth rates are in length on the gun-decks from 118 to 146 feet, and from 29 to 38 broad, they contain from 448 to 915 tons; carry from 226 to 346 men, and from 48 to 60 guns. Fifth rates have their gun-decks from 100 to 120 feet long, and from 24 to 31 broad; they contain from 259 to 542 tons; and carry from 145 to 190 men, and from 26 to 44 guns. Sixth rates have their gun-decks from 87 to 95 feet long, and from 22 to 25 broad; they contain from 152 to 256 tons, carry from 50 to 110 men, and from 16 to 24 guns.

It is to be observed, that the new built ships are much larger, as well as better than the old ones of the same rate; whence the double numbers all along: the larger of which expresses the proportions of the new-built ships, as the less those of the old ones. See the articles **SHIP** and **NAVY**.

**RATEEN**, or **RATTEN**, in commerce, a thick woollen stuff, quilled, woven on a loom with four treddles, like serges, and other stuffs, that have the whale or quilling.

**RATIFICATION**, *Ratificatio*, an act approving of, and confirming something done by another in our name.

**RATIO**, in arithmetic and geometry, is that relation of homogeneous things which determines the quantity of one from the quantity of another, without the intervention of a third.

Two numbers, lines, or quantities, A and B, being proposed, their relation one to another may be considered under one of these two heads: 1. How much A exceeds B, or B exceeds A; and this is found by taking A from B, or B from A; and is called arithmetic reason or ratio. 2. Or how many times, and parts of a time, A contains B, or B contains A; and this is called geometric reason or ratio; (or, as Euclid defines it, it is the mutual habitude, or respect, of two magnitudes of the same kind, according to quantity; that is, as to how often the one contains, or is contained in the other)

# R A T

and is found by dividing A by B, or B by A; and here note, that that quantity which is referred to another quantity, is called the antecedent of the ratio; and that to which the other is referred, is called the consequent of the ratio; as, in the ratio of A to B, A is the antecedent, and B the consequent. Therefore any quantity, as antecedent, divided by any quantity as a consequent, gives the ratio of that antecedent to the consequent.

Thus the ratio of A to B is  $\frac{A}{B}$ , but the ratio of B to

A is  $\frac{B}{A}$ ; and, in numbers, the ratio of 12 to 4 is

$\frac{12}{4} = 3$ , or triple; but the ratio of 4 to 12 is  $\frac{4}{12} = \frac{1}{3}$ , or subtriple.

And here note, that the quantities thus compared, must be of the same kind; that is such, which, by multiplication, may be made to exceed one the other, or as these quantities are said to have a ratio between them, which, being multiplied, may be made to exceed one another. Thus a line, how short soever, may be multiplied, that is produced so long as to exceed in length any given right line, and consequently these may be compared together, and the ratio expressed; but as a line can never, by any multiplication whatever, be made to have breadth, that is, to be made equal to a superficies, how small soever; these can therefore never be compared together, and consequently have no ratio or respect one to another, according to quantity; that is, as to how often the one contains, or is contained in another. See the article **PROPORTION**.

**RATIOCINATION**, *Ratiocinatio*, the act of reasoning. See **REASONING**.

**RATION**, or **RATIAN**, in the army, a portion of ammunition, bread, drink, and forage, distributed to each soldier in the army, for his daily subsistence, &c. The horse have rations of hay and oats when they cannot go out to forage. The rations of bread are regulated by weight. The ordinary ration of a foot soldier is a pound and a half of bread per day. The officers have several rations, according to their quality and the number of attendants they are obliged to keep. When the ration is augmented on occasions of rejoicing, it is called a double ration. The ships crews have also their rations or allowances of biscuit, pulse, and water, proportioned according to their stock.

**RATIONAL**, reasonable. See **REASON**.

**RATIONAL** is also applied to integral, fractional, and mixed numbers: thus we say, rational fractions, rational integer, and rational mixt number; for the explanation and doctrine of which, see **NUMBER** and **FRACTION**.

**RATIONALE**, a solution, or account of the prin-

principles of some opinion, action, hypothesis, phenomenon, or the like.

**RATLINES**, or, as the seamen call them, **RATLINS**, those lines which make the ladder steps to get up the shrouds and puttocks, hence called the ratlings of the shrouds.

**RATTLE-SNAKE**, *Crotalophorus*, in zoology, a genus of serpents, having scuta that cover the whole under-surface of the body and tail, and having the extremity of the body terminated by a kind of rattle, formed of a series of urceolated articulations, which are moveable, and make a noise.

Of this serpent, there are two species, the greater one with the scuta of the abdomen a hundred and seventy-two, of the tail twenty-one; and the lesser rattle-snake, having the scuta of the abdomen a hundred and sixty-five, of the tail twenty-eight. The larger is a very terrible, and at its full growth, a very large serpent, growing to eight feet in length, with a proportionable thickness: the head is large, broad, depressed, and of a pale brown: the iris of the eye is red; the back is of a brown colour, with an admixture of a ruddy yellow, and variegated with a great many irregular transverse lists, of a deep black; the belly is of a palish blue: the rattle is of a firm, and as it were of a horny substance, and brown colour, composed of a number of cells, which are articulated one within another, which articulations being very loose, the included points strike against the inner surface of the rings they are admitted into, and make that rattling noise, when the serpent vibrates, or shakes its tail. This serpent is frequent in the woods of America: the bite is fatal, but it is easy to avoid it, the creature being sluggish, moving slowly, never attacking a man unless provoked, and giving notice before it bites by shaking its rattle.

The lesser species of this serpent grows to about seven feet in length, and in most particulars is like the former one, and its bite is equally mischievous.

**RATTLE-SNAKE-ROOT**, the same with the senega, a species of the polygala. See the article **POLYGALA**.

**RAUCEDO**, hoarseness, in medicine. See the article **HOARSENESS**.

**RAVELIN**, in fortification, was anciently a flat bastion, placed in the middle of a curtain; but now a detached work composed only of two flanks, which make a salient angle, without any faces, and raised before the curtain on the counterscarp of the place. A ravelin is a triangular work, resembling the point of a bastion, with the flanks cut off.

**RAVEN**, in ornithology, a species of the curvus, of the bigness of a common hen, of a black colour, with a blue back: the head is small, depressed on the crown, and flattened on both sides: the eyes are large, bright and piercing; the beak is considerably long, and somewhat ridged on the back, and sharp at the point.

**RAVISHMENT**, in law, denotes an unlawful seducing either of a woman, or an heir that is in ward: sometimes it is also used in the same sense as a rape.

**RAUVOLFIA**, in botany, a genus of plants, whose flower is monopetalous and funnel-shaped; the tube is cylindrical and globose at the base, and the limb is divided into five roundish emarginated segments. The fruit is a subglobose, unilocular drupe, containing a bilocular nut, convex at the base, and depressed at the top.

**RAY**, in optics, a beam of light, emitted from a radiant, or luminous body. See **LIGHT**.

**RAYONANT**, or *Cross* **RAYONANT**, in heraldry, one which has rays of glory behind it, darting out from the center to all the quarters of the escutcheon.

**RE**, in grammar, an inseparable particle added to the beginning of words, to double, or otherwise modify their meaning; as in re-action, remove, re-export, &c.

**REACH**, in the sea-language, signifies the distance between any two points of land, lying nearly in a right line.

**RE-ACTION**, in physiology, the resistance made by all bodies to the action or impulse of others, that endeavour to change its state, whether of motion or rest. See the articles **ACTION** and **MOTION**.

**REALISTS**, *Realistæ*, a sect of school philosophers, formed in opposition to the nominalists. See **NOMINALISTS**.

Under the realists are included the Scotists, Thomists, and all excepting the followers of Ockham. Their distinguishing tenet is, that universals are realities, and have an actual existence out of an idea, or imagination; or, as they express it in the schools, a *parte rei*; whereas the nominalists contend that they only exist in the mind, and are only ideas, or manners of conceiving things.

**REAR**, a term frequently used in composition, to denote something behind, or backwards, in respect of another, in opposition to van: thus, in a military sense, it is used for the hind part of an army, in opposition to the front. For the rear-guard, rear-half-files, rear-line, rear-rank, and rear-admiral, see **GUARD**, **FILE**, **LINE**, **RANK**, and **ADMIRAL**.

**REASON**, *Ratio*, a faculty, or power of the mind, whereby it distinguishes good from evil, truth from falsehood; whereby man is distinguished from beasts; and wherein it is evident he greatly surpasses them: or, reason is that principle, whereby, comparing several ideas together, we draw consequences from the relations they are found to have. See **REASONING**.

**REASON** is also taken in different other significations; sometimes it denotes true and clear principles; sometimes it is taken for clear and fair de-

deductions from these principles; and sometimes for the cause,, particularly the final cause.

**REASONING**, ratiocination, the exercise of that faculty of the mind called reason; or it is an act or operation of the mind, deducing some unknown proposition from other previous ones that are evident and known.

It often happens in the comparing ideas together, that their agreement or disagreement cannot be discerned at first view, especially if they are of such a nature as not to admit of any exact application to one another: here then, as has been already observed under **REASON**, it becomes necessary to look out some third idea that will admit of such an application as the present case requires. Hence it appears that every act of reasoning necessarily includes three distinct judgments, two wherein the ideas whose relation we want to discover, are severally compared with the middle idea, and a third wherein they are themselves connected, or disjointed according to the result of that comparison. Now as our judgments when put into words are called propositions, so the expressions of our reasonings are termed syllogisms. And hence it follows that as every act of reasoning implies three several judgments, so every syllogism must include three distinct propositions. See the article **SYLLOGISM**.

In order therefore to infer a conclusion by a single act of reasoning, the premises must be intuitive propositions where, they are not, previous syllogisms are required, in which case reasoning becomes a complicated act taken in a variety of successive steps. This frequently happens in tracing the more remote relations of our ideas, where many middle terms being called in, the conclusion cannot be made out, but in consequence of a series of syllogisms following one another in train. Hence we may clearly perceive that reasoning, in the highest exercise of that faculty, is no more than an orderly combination of simple acts of reasoning. See **DEMONSTRATION**.

Thus we see that reasoning, beginning with first principles, rises gradually from one judgment to another, and connects them in such a manner that every stage of the progression brings intuitive certainty along with it.

**REAUMURIA**, in botany, a genus of plants, whose corolla consists of five oblong equal petals, which are recurved at their tops; the filaments are numerous and topped with roundish antheræ; the fruit is an ovate capsule, having five valves, and five cells containing a great many oblong seeds.

**REBATE**, or **REBATEMENT**, in commerce, a term much used at Amsterdam, for an abatement in the price of several commodities, when the buyer, instead of taking time, advances ready money.

**REBATEMENT**, in heraldry, a diminution

or abatement of the bearings, in a coat of arms. See **ABATEMENT**.

**REBELLION**, a traiterous taking up of arms against the king by his own natural subjects, or those formerly subdued.

**REBELLIOUS-ASSEMBLY**, in law, an assembling together of twelve or more persons, with an intent of unlawfully making use of their own authority, to change or alter any laws of this kingdom, or to destroy the inclosures of any ground, or the banks of any fish-pond, pool, or conduit, to the intent that it may lie waste and void; or to destroy, the deer in any park, fish in fish-ponds, coney in any warren; or any house, barn, mills, or bays; or to burn sacks of corn, abate rents, or prices of victuals, &c. See the article **RIOT**.

**REBUS**, an ænigmatical representation of some name &c. by using figures or pictures instead of words, or parts of words.

**REBUTTER**, in law, the defendant's answer to the plaintiff's surrejoinder, in a cause depending in the court of chancery, &c.

**RECAPITULATION**, in oratory, &c. a part of the peroration.

Recapitulation is a summary, or a concise and transient enumeration of the principal things insisted on in the preceding discourse, whereby the force of the whole is collected into one view.

**RECEIPT**, or **RECEIT**, in commerce, an acquittance, or discharge, in writing, intimating that the party has received a certain sum of money, either in full for the whole debt, or in part, or on account.

**RECEIPT**, in book-keeping, is an account of all the money and goods received. See the article **BOOK**.

**RECEIPT**, in medicine. See **RECIPE**.

**RECEIVER**, in chemistry, a vessel of earth, glass, &c. for receiving any distilled liquor.

**RECEIVER**, in Pneumatics, a glass-vessel for containing the thing on which an experiment in the air-pump is to be made. See **AIR-PUMP**.

**RECEPTACLE**, among botanists, is the base which supports either the flower, fruit, or seeds; in respect to its form it is either flat, concave, convex, globular, conic, or pyramidal; and with regard to its surface, it is either naked, punctated, villose, bristly or paleaceous.

**RECEPTACULUM CHYLI**, or **PECQUET'S RESERVATORY**, the reservoir or receptacle for the chyle, situated in the left side of the upper vertebra of the loins, under the aorta, and the vessels of the left kidney.

**RECHABITES**, a kind of religious order among the antient Jews, instituted by Jonadab, the son of Rechab, comprehending only his own family and posterity.

Their founder prescribed them three things: first, not to drink any wine; secondly, not to build any houses, but to dwell in tents; and thirdly, not to sow any corn, or plant vines. These rules the Rechabites observed with great strictness.

**RECHEAT**, in hunting, a lesson which the huntsmen play on the horn, when the hounds have lost their game, to call them back from pursuing a counter-scent.

**RECIPE**, in medicine, a prescription or remedy, to be taken by a patient; so called, because always beginning with the word *recipe*, *i. e.* take; which is generally denoted by the abbreviature R.

For the rules proper to be observed in forming recipes, see **PRESCRIPTION**.

**RECIPIANGLE**, or **RECIPIENT-ANGLE**, a mathematical instrument, serving to measure re-entering and salient angles, especially in fortification.

**RECIPIENT**, the same with receiver. See the article **RECEIVER**.

**RECIPROCAL**, in general, something that is mutual, or which is returned equally on both sides, or that affects both parties alike.

**RECIPROCAL TERMS**, among logicians, are those which have the same signification; and consequently are convertible, or may be used for each other.

**RECIPROCAL FIGURES**, in geometry, those which have the antecedents and consequents of the same ratio, in both figures.

**RECIPROCAL PROPORTION**, in arithmetic, is when in four numbers, the fourth is less than the second, by so much as the third is greater than the first; and *vice versa*. See the article **PROPORTION**.

**RECITATIVO**, or **RECITATIVE**, in music, a kind of singing, that differs but little from ordinary pronunciation, such as that in which the several parts of the liturgy are rehearsed in cathedrals; or that wherein the actors commonly deliver themselves on the theatre at the opera, when they are to express some action or passion, to relate some event, or reveal some design.

**RECKONING**, or, *a Ship's RECKONING*, in navigation, is that account whereby at any time it may be known where the ship is, and on what course or courses she is to steer, in order to gain her port; and that account taken from the log-board is called the dead-reckoning. See **LOG-BOARD**, **JOURNAL**, &c.

**RECLUSE**, among the papists, a person shut up in a small cell of an hermitage, or monastery, and cut off, not only from all conversation with the world, but even with the house. This is a kind of voluntary imprisonment, from a motive either of devotion or penance.

The word is also applied to incontinent wives, whom their husbands procure to be thus kept in perpetual imprisonment in some religious house.

Recluses we antiently very numerous; they took an oath, never to stir out of their retreat; and having entered it, the bishop set his seal upon the door; and the recluse was to have every thing necessary for the support of life, conveyed to him through a window.

**RECOGNITION**, in law, an acknowledgment; a word particularly used in our law-books, for the first chapter of the statute 1 Jac. I. by which the parliament acknowledged, that, after the death of queen Elizabeth, the crown had rightfully descended to king James.

**RECOGNIZANCE**, or **RECOGNISANCE**, in law, a bond or obligation of record, acknowledged to the king; thus called, because recognized or acknowledged in some court of record, or before some judge, master in chancery, or justice of the peace.

The party bound in a recognizance, is called recognizor; and the person to whom he is bound, is termed the recognizee.

**RECOIL**, or **REBOUND**, the starting backward of a fire-arm, after an explosion.

Mersennus tells us, that a cannon 12 feet in length, weighing 6400 lb. gives a ball of 24 lb. an uniform velocity of 640 feet per second. Putting therefore,  $W = 6400$   $w = 24$ ,  $V = 640$ , and  $v =$  the velocity with which the cannon recoils; we shall have (because the momentums of the cannon and ball are equal)  $Wv = wV$ ; and so  $v = \frac{wV}{W} = \frac{24 \times 64}{6400} = 2, 4$ ; that is, it would recoil at the rate of  $2\frac{4}{10}$  feet per second, if free to move. See **GUNNERY** and **PROJECTILE**.

**RECOLLECTION**, a mode of thinking, by which ideas sought after by the mind, are found, and brought again to view.

**RECOLLECTS**, a congregation of reformed Franciscans, called also friars-minors of St. Francis, of the strict observance. See **FRANCISCANS**.

**RECONNOITRE**, in war, to view and examine the state and situation of things.

**RECORD**, an authentic testimony in writing, contained in rolls of parchment, and preserved in a court of record.

Records are said to be of three kinds, viz. a record judicial, an attainder, &c. a record ministerial, upon oath, as an office or inquisition found; and a record made by conveyance and consent, as a fine, &c.

**RECORDER**, a person whom the mayor and other magistrates of a city or corporation associate to them, for their better direction in matters of justice, and proceedings in law; on which account this person is generally a counsellor, or other person well skilled in the law.

**RECOVERY**, in law, is obtaining any thing by judgment or trial at law.

**RECREMENT**, in chemistry, some superfluous matter separated from some other that is useful;

in which sense it is the same with *scoriæ*, *facès*, and excrements. See the article *SCORIÆ*, &c.

**RECRIMINATION**, in law, an accusation brought by the accused against the accuser, upon the same fact. See the article *ACCUSATION*.

**RECRUITS**, in military affairs, new-raised soldiers, designed to supply the place of those who have lost their lives in the service, or are disabled by age or wounds.

**RECTANGLE**, in geometry, the same with a right-angled parallelogram. See the article *PARALLELOGRAM*.

In arithmetic and algebra, a rectangle signifies the same with *factum* or *product*. See the articles *PRODUCT* and *MULTIPLICATION*.

**RECTANGLED, RECTANGULAR, or RIGHT-ANGLED**, appellations given to figures and solids which have one or more right angles: thus a triangle with one right angle, is termed a rectangled triangle; also parallelograms with right angles, squares, cubes, &c. are rectangular.

Solids, as cones, cylinders, &c. are also said to be rectangular, with respect to their situation, when their axes are perpendicular to the place of the horizon.

The ancient geometers always called the parabola, the rectangular section of a cone. See the articles *CONIC SECTIONS* and *PARABOLA*.

**RECTIFICATION**, the art of setting any thing to rights: and hence, to rectify the globes, is to fit them for performing any problem. See the article *GLOBE*.

**RECTIFICATION**, in geometry, is the finding a right line, equal in length to a curve. See the article *CURVE*.

**RECTIFIER**, in navigation, an instrument consisting of two parts, which are two circles either laid one upon, or let into, the other, and so fastened together in their centers, that they represent two compasses, one fixed, the other moveable; each of them divided into the thirty-two points of the compass, and three hundred and sixty degrees, and numbered both ways, from the north and the south, ending at the east and west, in ninety degrees.

The fixed compass represents the horizon, in which the north and all the other points of the compass are fixed and immoveable.

The moveable compass represents the mariners compass, in which the north and all other points are liable to variation.

In the center of the moveable compass is fastened a silk thread, long enough to reach the outside of the fixed compass. But, if the instrument be made of wood, there is an index instead of the thread.

Its use is to find the variation of the compass, to rectify the course at sea; having the amplitude or azimuth given.

**RECTILINEAR**, in geometry, right-lined;

thus figures whose perimeter consists of right lines, are said to be rectilinear.

**RECTOR**, a term applied to several persons whose offices are very different: as, 1. The rector of a parish is a clergyman that has the charge and cure of a parish, and possesses all the tythes, &c. 2. The same name is also given to the chief elective officer in several foreign universities, particularly in that of Paris. 3. Rector is also used in several convents for the superior officer who governs the house; and the Jesuits give this name to the superiors of such of their houses as are either seminaries or colleges.

**RECTORY**, a parish-church, parsonage, or spiritual living, with all its rights, tythes and glebes.

Rectory is also used for the rector's mansion or parsonage-house.

**RECTUM**, in anatomy, the third and last of the large intestines, or guts. See *INTESTINES*.

The rectum is in length about three hands breadth, and its diameter about three fingers. It has its beginning at the lowest vertebrae of the loins, and at the lower end is the anus. See *ANUS*.

It is connected to the os sacrum, the os coccygis, and the urinary bladder in men; but in women to the vagina uteri. The coats of the rectum are more thick and fleshy than those of any other of the intestines: it has in general no valves, but it has several rugæ: the absence of valves here, is to prevent the expulsion of the feces from being retarded.

**RECTUS**, in anatomy, a name common to several pair of muscles, so called on account of the straightness of their fibres, as, 1. The rectus major anticus, which arises from the transverse apophyses of the five lower vertebrae of the neck, and is inserted in the os occipitis. 2. The rectus minor anticus, called, by Cowper, *musculus annuens*; this arises from the anterior surface of the atlas, or first vertebra of the neck; and lies concealed, as it were, under the former, till it is at length inserted a little behind it, into the os occipitis: these two pair of muscles serve to move the head forward. 3. The rectus major posticus, one of the extensors of the head, which has its origin from the spinose apophysis of the epistropheus, and is inserted into the os occipitis. 4. The rectus minor posticus, which is also one of the five extensors of the head, has its rise from the posterior part of the atlas, and its end under the former. 5. The rectus lateralis, which serves to bend the head on one side, has its origin from the upper surface of the transverse apophysis of the atlas: from this it ascends straight with a short body, but considerably thick; and is inserted partly into the os occipitis, and partly into the temporal bone, near the incisure of the mastoid process. 6. The rectus tibiae, one of the four extensors of the leg, which has its origin from the anterior and inferior spine of the ileum.

**RECTUS IN CURIA**, in law, one who stands at the

the bar, and no man objects any thing against him. So also when a person who has been outlawed has reversed the outlawry, and can partake of the benefit of the law, he is said to be *rectus in curia*.

**RECURRENTS**, in anatomy, a name given to several large branches of nerves sent out by the par vagum from the upper part of the thorax to the larynx.

**RECUSANTS**, such persons as acknowledge the pope to be the supreme head of the church, and refuse to acknowledge the king's supremacy; who are hence called popish recusants. These are in England charged with double taxes, not merely as Romanists, but as recusants.

**RED**, in physics, one of the simple or primary colours of natural bodies, or rather of the rays of light. See **COLOUR**, **LIGHT**, and **RAY**.

**RED**, in dying, is one of the five simple or mother colours: some reckon six kinds or casts of red, viz. scarlet-red, crimson-red, madder-red, half-grain-red, lively-orange-red, and scarlet of cochineal: but they may be all reduced to the three following, according to the three principal drugs which give the colours, viz. the kermes, cochineal, and madder. See the articles **KERMES**, **COCHINEAL**, and **MADDER**.

For the scarlet and crimson reds, see **SCARLET** and **CRIMSON**.

Madder-red is made with madder, to which some add realgal and arsenic; others common salt, or other salts, with wheat-flour; or agaric, with spirit of wine, galls, or turmeric. The half-grain is made with agaric and bran-water; half-scarlet-grain, half madder, and sometimes turmeric. As to the lively orange-red, the stuff must be first put in yellow, then in a liquor made of goats hair, which has been boiled several times with madder, and now dissolved over the fire with certain acids, as urine, tartar, &c.

Besides these reds, which are good and allowed colours, there is also a Brazil red, which is discouraged as fading easily.

Of the six good reds, only four have particular casts or shades, the madder-red, the crimson-red, the lively orange-red, and the scarlet of cochineal: the casts or shades of crimson are flesh-colour, peach-colour, carnation-rose-colour, and an apple-tree-flower-colour: those of madder are a flesh-colour, onion-peel-colour, and flame-colour: those of the orange are the same with that of the crimson: scarlet, besides the shades of all the rest, has some peculiar to itself, as cherry-colour, fire-colour, &c.

**RED**, in painting. For painting in oil-colours, they use a red called cinnabar, or vermilion, and another called Lacca.

In limning and fresco, for a violet-red, instead of lacca they use reddle, a natural earth found in England: for a brown, they use ochre.

**RED**, in heraldry. See **GULES**.

**RED-BOOK** of the *Exchequer*, an ancient record or manuscript volume, in the keeping of the king's remembrancer, containing divers miscellany treatises relating to the times before the conquest.

**REDDLE**, a soft, heavy, red marle, of great use in colouring; and being washed and freed from its sand, is often sold by our druggists under the name of bole-armenic.

**REDEEMABLES**, are lands, funds, &c. sold with a reservation of the equity of redemption. See **REDEMPTION**.

**REDELIVER**, the yielding and delivering a thing back, which in case of a robbery, &c. does not purge the offence.

**REDEMISED**, signifies the granting back of lands demised or leased.

**REDEMPTION**, in law, a faculty or right of re-entering upon lands, &c. that have been sold and assigned, upon re-imbursing the purchase money with legal costs.

Bargains wherein the faculty, or, as some call it, the equity, of redemption is reserved, are only a kind of pignorative contracts. A certain time is limited within which the faculty of redemption shall be exercised, and beyond which it shall not extend.

In our old law-writers, redemption denoted some grievous mulct, imposed by way of commutation for the head or life of the delinquent.

**REDENS**, **REDANS**, or **REDANT**, in fortification, a kind of work indented in form of the teeth of a saw, with salient and re-entering angles, to the end that one part may flank or defend another. It is called saw-work and indented work. The faces in this, flank one another.

Redens are frequently used in the fortifying of walls, where it is not necessary to be at the expence of building bastions; as when they stand on the side of a river, a marsh, the sea, &c.

**REDOUBT**, or **REDOUTE**, *Reductus*, in fortification, a small square fort, without any defence but in front, used in trenches, lines of circumvallation, contravallation, and approach, as also for the lodgings of the corps-de-garde, and to defend passages. In marshy grounds, redoubts are frequently made of stone-works, for the security of the neighbourhood; their face consists of from ten to fifteen fathom, the ditch round them from eight to nine feet broad and deep, and their parapets have the same thickness.

**REDUCT**, or **REDUIT**, a military term signifying an advantageous piece of ground, entrenched, and separated from the rest of the place, camp, &c. for an army, garrison, &c. to retire to in case of a surprize.

**REDUCT**, in building, a quirk or little place taken out of a larger to make it more uniform and

regular; or for some other convenience, as for a little cabinet, a side of a chimney, for alcoves, &c.

**REDUCT**, or **REDUX**, among chemists, a powder by which calcined metals and minerals are again reduced to their regulus, or pure substance. See **REGULUS**.

**REDUCTION**, *Reductio*, in the schools, a manner of bringing a term or proposition which was before opposite to some other, to be equivalent to it.

**REDUCTION of Syllogisms**, is a regular changing or transforming of an imperfect syllogism into a perfect one; or it is a change of a syllogism in respect of form whereby the necessity of the illation or inference is made more evident. See the article **SYLLOGISM**.

**REDUCTION**, in arithmetic, that rule whereby numbers of different denominations are brought into one denomination.

Reduction is but the application of multiplication and division. For, first, a higher denomination is brought into a lower one, by multiplying the higher denomination with so many of the lower, as are contained in the higher; still keeping them equivalent in value. This is called reduction descending. Secondly, a lower or inferior denomination is reduced into a higher or superior one, by dividing the lesser one with so many of its denomination as is contained in the greater. This is the converse of the last, and is termed reduction ascending.

Thus pounds are reduced into shillings by multiplying with 20; shillings into pence, by multiplying with 12; and pence into farthings, by multiplying with 4. On the other hand, shillings are reduced into pounds, by dividing with 20; pence into shillings, by dividing with 12; and farthings into pence by dividing with 4.

Examples. Let it be required to reduce 357l. into shillings, and those shillings into pence;  $357 \times 20 = 7140 =$  the shillings in 357l. and  $7140 \times 12 = 85680 =$  the pence in 357l. as was required. Again, let it be required to reduce 85680d. into shillings, and those shillings into pounds;  $85680 \div 12 = 7140 =$  the shillings in 357l. and  $7140 \div 20 = 357l.$  as was required.

If there remain any thing in each division, it is respectively either odd pence, shillings, or farthings; thus 4123788 farthings being reduced, give 4295l. 12s. 3d.

But when the numbers proposed to be reduced are of several denominations, and it is required to bring them all to the lowest, you must reduce, as before, the highest or greatest denomination to the next less, adding the numbers that are of that next denomination together; then reduce their sum to the next lower denomination; adding together all the

numbers that are of that denomination, and so proceed gradually on until all is done.

To expedite the practice of this rule, several compendious ways of reduction have been invented. See **PRACTICE**.

**REDUCTION of Fractions**. See the article **FRACTION**.

**REDUCTION of Equations**, in algebra. See the article **EQUATION**.

**REDUCTION of Curves**. See the article **CURVE**.

**REDUCTION of a Figure, Design, or Draught**, is the making a copy thereof, either larger or smaller than the original; still preserving the form and proportion. The great use of the proportional compasses is the reduction of figures, &c. whence they are called compasses of reduction.

**REDUCTION to the Ecliptic**, in astronomy. The place of any star reduced to the ecliptic, is that point where the secondary passing through the star intersects the ecliptic.

**REDUCTION**, in metallurgy, is the bringing back metalline substances which have been changed into scoria or ashes, or otherwise divested of their metallic form, into their natural and original state of metals again. All metals and semi-metals may be reduced by proper management, whatever have been their changes, except only zink, which having been burnt to ashes, admits of no reduction; but the mixture of gold and silver was never yet radically dissolved by any experiment, whatever some may have imagined. Even some earths will turn into metals by the admixture and intimate union of a phlogiston or inflammable principle.

**REDUCTION**, in surgery denotes an operation whereby a dislocated, luxated, or fractured bone is restored to its former state or place. See the articles **LUXATION** and **FRACTURE**.

**REDUNDANT HYPERBOLA**, is a curve of the higher kind, thus called because it exceeds the conic section of that name, in the number of its hyperbolical legs; being a triple hyperbola with six hyperbolical legs.

**REDUPLICATION**, in logic, a kind of condition expressed in a proposition indicating, or assigning the manner wherein the predicate is attributed to the subject. Hence reduplicative propositions, are such wherein the subject is repeated with some circumstance or condition. Thus, *men, as men, are rational: kings, as kings, are subject to none but God.*

**REED**, an ancient Jewish measure. See the article **MEASURE**.

**REED**, *Arundo*, in botany, a genus of gramineous plants; the flowers grow in spikes, the corolla of which consists of two oblong acuminate valves, having a down at their base, which rises almost their length: the stamina are three capillary filaments, topped with horned antheræ; there is no pericarpium, but the corolla contains a single oblong

oblong pointed seed, with a long down adhering to its base.

The common reed grows in plenty by the sides of rivers and large standing waters, in many parts of England: they are cut in autumn, and applied to many uses. To this genus belong the bamboe, which grows in plenty in the East-Indies. See the article BAMBOE.

REEF, a term in navigation. When there is a great gale of wind, they commonly roll up part of the sail below, that by this means it may become the narrower, and not draw so much wind; which contracting or taking up the sail they call a reef, or reefing the sail: so also when a top-mast is sprung, as they call it, that is, when it is cracked, or almost broken in the cap, they cut off the lower piece that was near broken off, and setting the other part, now much shorter, in the step again, they call it a reefed top-mast.

REEL, in the manufactories, a machine serving for the office of reeling.

REELING, in the manufactories, the winding of thread, silk, cotton, or the like, into a skain, or upon a bottom, to prevent its entangling. It is also used for the charging or discharging of bobbins or quills, to use them in the manufacture of different stuffs, as thread, silk, cotton, &c. Reeling is performed different ways, and on different engines.

RE-ENTRY, in law, signifies the resuming or retaking that possession which any one had lately forgone; as where a person makes a lease of lands to another, the lessor thereby quits the possession, and if the lessee covenants that upon non-payment of the rent reserved, the lessor may lawfully re-enter, being as much as if it was conditioned for the lessor to take the land again into his hands, and recover the possession again by his own act without the assistance of the law. Likewise, if a lease for years be made, with condition that if the lessee assign his terms, the lessor may re-enter, and the lessee, in breach of the condition, assigns unknown to the lessor, who accepts of rent from the assignee without notice of the assignment, in that case it is held the lessor may re-enter, notwithstanding his acceptance of the rent.

REEVE of a Church, the guardian of it, or the churchwarden. See CHURCH.

REEVING, in the sea language, the putting a rope through a block: hence, to pull a rope out of a block, is called unreeling.

RE-EXCHANGE, in commerce, a second payment of the price of exchange, or rather the price of a new exchange due upon a bill of exchange that comes to be protested and to be refunded the bearer by the drawer or indorser. See the articles EXCHANGE and BILL.

REFECTION, among ecclesiastics, a spare meal or repast just sufficing for the support of life:

hence the hall in convents, and other communities, where the monks, nuns, &c. take their refectons or meals, in common, is called the refectory.

REFERENCE, in writing, &c. a mark relative to another similar one in the margin, or at the bottom of the page, where something omitted in the text is added, and which is to be inserted either in reading or copying. References are also used in books where things being but imperfectly handled, the reader is directed to some other part or place for a further explanation of them. For the use of these references in a work of this kind, we refer the reader to what has been said upon that subject in our introduction to this work.

REFINING, in general, is the art of purifying a thing; including not only the assaying or refining of metals, but likewise the clarification of liquors. See ASSAYING and CLARIFICATION.

REFLECTING or REFLECTIVE DIAL. See the article DIAL.

REFLECTION, or REFLEXION, in mechanics, the return or regressive motion of a moving body, occasioned by some obstacle which hindered it from pursuing its former direction.

For the laws of the reflection of moving bodies, see MOTION, COMMUNICATION of Motion, and PERCUSSION.

REFLECTION of the Rays of Light, in catoptrics, is their return, after approaching so near the surfaces of bodies, as to be thereby repelled, or driven back. See the article MIRROR.

REFLECTION of the Moon, the same with her variation. See the article VARIATION.

REFLECTION, is also used, figuratively, for an operation of the mind; whereby it turns its view backwards, as it were, upon itself, and makes itself and its own operation the object of its disquisition; and by contemplating the manner, order, and laws, which it observes in perceiving ideas, comparing them together, reasoning, &c. it frames new ideas of the relations discovered therein. See the articles IDEA, KNOWLEDGE, REASONING, &c.

REFLEX, or REFLECT, in painting, is understood of those places in a picture which are supposed to be illuminated by a light reflected from some other body, represented in the same piece.

REFLEX VISION, that performed by means of reflected rays, as from mirrors. See the articles VISION and MIRROR.

REFLUX of the Sea, the ebbing of the water, or its returning from the shore. See the article TIDE.

REFORM, a re-establishment, or revival, of formerly-neglected discipline, or a correction of the reigning abuses therein.

To REFORM, in a military sense, is to reduce a company, regiment, &c. either by disbanding the whole, or breaking a part, and retaining the rest.

RE-

## REF

**REFORMADO**, or **REFORMED OFFICER**, one whose troop, or company, is suppressed in a reform, and he continued either in the whole or half-pay, doing duty in the regiment.

**REFORMATION**, the act of reforming, or correcting an error or abuse in religion, discipline, or the like.

The reformation, so called by way of eminence, is the separation of the Protestants from the church of Rome, in the beginning, and towards the middle, of the sixteenth century. See the articles **LUTHERANS**, &c.

**REFRACTED** or **REFRACTIVE DIAL**, one that shews the hours by means of some refractive transparent fluid. See **DIAL**.

**REFRACTION**, in general, is the deviation of a moving body from its direct course, occasioned by the different density of the medium it moves in; or, it is a change of direction, occasioned by a body's falling obliquely out of one medium, into another of a different density.

The great law of refraction, which holds in all bodies, and all mediums, is, that a body, passing obliquely out of one medium into another wherein it meets with less resistance, is refracted or turned towards the perpendicular; and, on the contrary, in passing out of one medium into another wherein the resistance is greater, it is refracted or turned from the perpendicular. Hence, the rays of light, falling out of air into water, are refracted towards the perpendicular; whereas a ball, thrown into the water, is refracted from it.

Now, the reason of this difference is, that water, which resists the motion of light less than air, resists that of the ball more; or, to speak more justly, because water, by its greater attraction, accelerates the motion of the rays of light more than air does.

**REFRACTION**, in astronomy, the refraction of the rays of light, issuing from a heavenly body, in passing through the atmosphere of our earth.

**REFRACTION of Altitude**, is an arch of a vertical circle, whereby the altitude is increased by the refraction.

**REFRACTION of Declination**, is an arch of a circle of declination, whereby the declination of the object is either increased or diminished by the refraction.

**REFRACTION of Longitude**, is an arch of the ecliptic, whereby the longitude of the object is increased or diminished by the refraction.

**REFRACTION of Latitude**, is an arch of a circle of latitude, whereby the latitude of a heavenly object is either increased or diminished by its refraction.

**REFRACTION in Island Crystal**. There is a double refraction in this substance, contrary ways, whereby not only oblique rays are divided into two, and refracted into opposite parts, but even perpendicular rays, and one half refracted.

*Causæ by REFRACTION.* See the article **DIACAUSTIC**.

## REG

**REFRANGIBILITY of Light**, the disposition of rays to be refracted. See **LIGHT**, **RAY**, and **REFRACTION**.

**REFRIGERATIVE**, in medicine, a remedy which refreshes the inward parts, by cooling them; as clysters, ptyfans, &c.

**REFRIGERATORY**, in chemistry, a vessel filled with cold water, through which the worm passes in distillations; the use of which is to condense the vapours, as they pass through the worm.

**REFUGE**, a sanctuary or asylum. See the article **ASYLUM**.

**REFUGEES**, French protestants, who by the revocation of the edict of Nantz, have been constrained to fly from persecution and take refuge in foreign countries.

**REGAL**, or **ROYAL**, something belonging to a king. See **ROYAL**.

**REGARDANT**, in heraldry, signifies looking behind, and is used for a lion, or other beast, with his face turned towards his tail.

**REGEL**, or **RIGEL**, a fixed star of the first magnitude, in Orion's left foot. See **ORION**.

**REGENERATION**, in theology, the act of being born again by a spiritual birth, or the change of heart and life; experienced by a person who forsakes a course of vice, and sincerely embraces a life of virtue and piety.

**REGENT**, one who governs a kingdom during the minority or absence of the king.

In France, the queen-mother has the regency of the kingdom, during the minority of the king, under the title of queen regent.

**REGENT**, also signifies a professor of arts and sciences in a college, who has a set of pupils under his care: but here regent is generally restrained to the lower classes, as regent of rhetoric, regent of logic, &c. those of philosophy are rather called professors.

The foreign universities are generally composed of doctors, professors, and regents.

**REGICIDE**, king-killer, a word chiefly used with us in speaking of the persons concerned in the trial, condemnation, and execution, of king Charles I.

**REGIMEN**, the regulation of diet, and in a more general sense, of all the non-naturals, with a view to preserve or restore health.

Dr. Mead observes, with respect to regimen, that diseases from inanition are generally more dangerous than those which proceed from repletion, because we can more expeditiously diminish than increase the juices of the body.

Upon this account, though temperance is beneficial to all men, the ancient physicians advised persons in good health to indulge a little now and then, by eating and drinking more plentifully than usual: but of the two, intemperance in drinking is safer than

than in eating; and if a person has committed excess in the latter, cold water drank upon a full stomach will help digestion; to which it will be of service to add lemon-juice or elixir of vitriol, if he has eaten high-seasoned things, rich sauces, &c. Then let him sit up for some time, and afterwards sleep. But if a man happens to be obliged to fast, he ought to avoid all laborious work.

From satiety it is not proper to pass directly to sharp hunger, nor from hunger to satiety; neither will it be safe to indulge absolute rest immediately after excessive labour, nor suddenly to fall to hard work after long idleness. In a word, all changes in the way of living should be made by degrees.

It is also beneficial to vary the scenes of life, to be sometimes in the country, sometimes in town; to go to sea, to hunt, to be at rest now and then, but more frequently to use exercise, and a moderate sleep. See EXERCISE, and SLEEP.

The passions and affections of the mind produce very sensible effects. Joy, anger, fear, and sorrow, are the principal. In joy, or anger, the spirits are hurried with too great vivacity; in fear, or dread, they are, as it were, curbed and concentrated; and continual sorrow and anguish of mind, render the fluids of the body thick, and the blood unapt for a due circulation, whence proceed many chronic diseases: it is therefore, on all accounts, as much our interest as our duty, to keep the passions within due bounds, and to preserve an inward serenity, calmness, and tranquility.

REGIMEN, in chemistry, signifies the due regulation of fire. See FIRE.

REGIMEN, in grammar, that part of syntax, or construction, which regulates the dependency of words, and the alterations which one occasions in another.

REGIMENT, in war, is a body of men, either horse or foot, commanded by a colonel.

Each regiment of foot is divided into companies, but the number of companies is not always alike, though our regiments generally consist of thirteen companies, one of which is always grenadiers.

Regiments of horse most commonly consist of six troops, but some have nine.

Regiments of dragoons, in time of war, are generally composed of eight troops, and in time of peace, of six. Each regiment has a chaplain and a surgeon. See TROOP and COMPANY.

Some German regiments consist of two thousand foot, and the regiment of Picardy in France, consists of 120 companies, or 6000 men.

REGION, in geography, a large extent of land, inhabited by many people of the same nation, and inclosed within certain limits or bounds.

The modern astronomers divide the moon into several regions, or large tracts of land, to each of which they give its proper name.

REGION, in physiology, is taken for a division of our atmosphere, which is divided into the upper, middle, and lower regions. See ATMOSPHERE.

REGION, in anatomy, a division of the human body, otherwise called cavity, of which anatomists reckon three, viz. the upper region, or that of the head; the middle region, that of the thorax or breast; and the lower, the abdomen, or belly. See the articles HEAD, THORAX, and ABDOMEN.

REGISTER, a public book, in which is entered and recorded memoirs, acts, and minutes, to be had recourse to occasionally, for knowing, and proving matters of fact.

REGISTER, is also used for the clerk or keeper of a register.

REGISTER SHIPS, in commerce, are vessels which obtain a permission either from the king of Spain, or the council of the Indies, to traffic in the ports of the Spanish West-Indies; which are thus called, from their being registered before they sail from Cadiz for Buenos Ayres. Each of these permissions cost 30,000 pieces of eight; and by the tenor of the cedula, or permit, they are not to exceed 300 tons; but there is such a good understanding between the merchants, and the council of the Indies, that ships of 5 or 600 tons frequently pass unnoted; and though the quantity and quality of the merchandizes on board are always expressed, yet, by means of presents, the officers both in Spain and the Indies, allow them to load and unload vastly more than the permission expresses.

REGISTER, in printing, is disposing the forms on the press, so as that the lines and pages printed on one side of the sheet, fall exactly on those of the other.

REGISTER, among letter-founders, is one of the inner parts of the mould, in which the printing types are cast.

REGISTERS, in chemistry, are holes, or chinks with stopples, contrived in the sides of furnaces, to regulate the fire; that is, to make the heat more intense, or remiss, by opening them to let in the air, or keeping them close to exclude it.

REGISTRY, the office, books, and rolls, in which the proceedings in chancery, or any spiritual court, are registered.

REGLET, or RIGLET, in architecture, a flat narrow moulding, used chiefly in pannels and compartments, to separate the parts and members from one another, and to form knots, frets, and other ornaments.

REGLETS, or RIGLETS, in printing, are thin slips of wood, exactly plained to the body of the letter.

The smaller sorts are placed between the lines of poetry, and both those and the larger are used in filling up short pages, in forming the whites or distances between the lines of titles, and in adjusting the

the distances of the pages in the chase, so as to form register.

**REGRATOR**, or **REGRATER**, in law, formerly signified one who bought wholesale, or by the great, and sold again by retail; but the term is now used for one who buys any wares or victuals, and sells them again in the said market, or fair, or within five miles round it. See the article **FORESTALLING**.

**REGRATOR**, is also used for one who furbishes up old moveables to make them pass for new. And masons, who take off the outward surface of hewn stone, in order to whiten it, or make it look fresh again, are said to regrate.

**REGULAR**, denotes any thing that is agreeable to the rules of art: thus, we say a regular building, verb, &c. See the articles **BUILDING**, **VERB**, &c.

A regular figure, in geometry, is one whose sides, and consequently angles, are equal; and a regular figure with three or four sides, is commonly termed an equilateral triangle, or square, as all others with more sides are called regular polygons. See the articles **TRIANGLE**, **SQUARE**, and **POLYGON**.

**REGULAR Curves**, such as proceed gradually in the same geometrical manner, with regard to their curvities. See the article **CURVE**.

**REGULAR**, in a monastery, a person who has taken the vows; because he is bound to observe the rules of the order he has embraced. See **MONK**.

**REGULAR Priest**, a priest in some religious order; in contradistinction to a secular priest, or one that lives in the world at large. See **PRIEST**.

**REGULATION**, a rule or order prescribed by a superior, for the proper management of some affair.

**REGULATOR of a Watch**, the small spring belonging to the ballance; serving to adjust its motions, and make it go faster or slower. See the article **WATCH**.

**REGULUS**, in chemistry, an imperfect metallic substance, that falls to the bottom of the crucible, in the melting of ores, or impure metallic substances.

**REGULUS**, in astronomy, a star of the first magnitude, in the constellation *Leo*, called also from its situation, *cor leonis*, or, the lion's heart.

**REHEARSAL**, in music, and the drama, an essay or experiment of some composition generally made in private, previous to its representation or performance in public, in order to render the actors and performers more perfect in their parts.

**REIMBURSEMENT**, in commerce, the act of repaying another the expences he has been at on our account.

**REIN-DEER**, in zoology, a species of the

cervus, with horns ramose and cylindric, with their tops palmated.

This is a large and beautiful species, not inferior to the elk in size or strength, but greatly exceeding it in form; it is of the size of a small horse, but its shape is exactly that of the red deer. It is a native of the northern regions, there being no country so far north as not to afford it, where it is of vast use to the inhabitants, as a beast of draught.

**REINFORCED**, or **REINFORCED RING**, of a cannon, is the next after the trunnions, betwixt them and the touch-hole.

**REINFORCEMENT**, in war, a fresh supply of men, arms, ammunition, &c.

**REINS**, in anatomy, the same with kidneys. See **KIDNEYS**.

**REINS of a Bridle**, are two long slips of leather, fastened on each side of a curb or snaffle, which the rider holds in his hand, to keep his horse in subjection.

**REJOINING**, in architecture, filling up the joints of the stones in buildings. This ought to be performed with the best mortar, as that of lime and cement, and sometimes with plaster, as in the joints of vaults.

**REJOYNDER**, or **REJOINDER**, in law, is the defendant's answer to the plaintiff's replication or reply. Thus, in the court of chancery, the defendant puts in an answer to the plaintiff's bill, which is sometimes also called an exception; the plaintiff's answer to this is called a replication, and the defendant's answer to that a rejoinder.

**RELAPSE**, a falling again into a danger, evil, or disease, from which a person has escaped.

**RELATION**, *Relatio*, in philosophy, the mutual respect of two things, or what each is with regard to the other.

**RELATION**, among the ancient logicians, constituted one of the ten categories, or predicaments.

**RELATION**, in geometry, signifies the same with ratio. See **RATIO**.

**RELATION**, in grammar, is the correspondence which words have to one another in construction.

**RELATION** is also used for analogy. See the article **ANALOGY**.

**RELATION**, in law, is where two times, or other things, are considered as if they were one and the same; and by this the thing subsequent is said to take its effect, by relation, from the time preceding: thus, in case of a deed of bargain and sale inrolled, the inrollment shall have relation to the delivery thereof; and in our courts, a judgment has always relation to the first day of term.

**RELATIVE**, something relating to, or respecting another. See the preceding article.

**RELATIVE TERMS**, in logic, are words which imply a relation: such are master and servant, husband and wife, &c.

## R E L

**RELAXATION**, in medicine, &c. the act of loosening or slackening, or the looseness and slackness of the fibres, nerves, muscles, &c.

**RELAY**, a supply of horses placed on the road, and appointed to be ready for a traveller to change in order to make the greater expedition.

**RELAY**, in tapestry, is an opening left, where the colours and figures are to be changed, when the piece is finished.

**RELEASE**, in law, is an instrument in writing, by which estates, rights, titles, entries, actions, and other things, are extinguished and discharged; and sometimes transferred, abridged, or enlarged: and in general, it signifies one person's giving up or discharging the right of action he has, or claims to have, against another, or his lands, &c.

**RELICS**, in the Romish church, the remains of the bodies or cloaths of saints or martyrs, and the instruments by which they were put to death, devoutly preserved in honour to their memory; kissed, revered, and carried in procession.

This is a piece of superstition which began very early in the Christian church, and at present makes no inconsiderable article of popery.

**RELICT**, in law, the same with widow. See the article **WIDOW**.

**RELIEVE**, in a military sense, is to send off those men that are upon duty, and to bring others to take their place: thus, to relieve the guard, the trenches, &c. is to bring fresh men upon duty, and to discharge those who were upon duty before.

**RELIEVO**, or **RELIEF**, in sculpture, &c. is the projecture or standing out of a figure, which arises prominent from the ground or plan on which it is formed; whether that figure be cut with a chissel, moulded, or cast.

There are three kinds or degrees of relievos, viz. alto, basso, and demi-relievo. The alto-relievo, called also haut-relief, or high-relievo; is when the figure is formed after nature, and projects as much as the life. Basso-relievo, bass-relief, or low-relievo, is when the work is raised but a little from the ground, as in medals, and the frontispieces of buildings; and particularly in the histories, festoons, foliages, and other ornaments of friezes. Demi-relievo, is when one half of the figures rises from the plan. When, in a basso-relievo, there are parts that stand clear out, detached from the rest, the work is called a demi-basso.

In architecture, the relievo or projecture of the ornaments, ought always to be proportioned to the magnitude of the building it adorns, and to the distance at which it is to be viewed.

**RELIEVO**, or **RELIEF**, in painting, is the degree of boldness with which the figures seem, at a due distance, to stand out from the ground of the painting.

The relievo depends much upon the depth of the

## R E M

shadow, and the strength of the light; or on the height of the different colours, bordering on one another; and particularly on the difference of the colour of the figure from that of the ground: thus, when the light is so disposed as to make the nearest parts of the figures advance, and is well diffused on the masses, yet insensibly diminishing, and terminating in a large spacious shadow, brought off insensibly, the relievo is said to be bold, and the clair obscure well understood.

**RELIGION**, that worship and homage which is due to God, considered as our creator, preserver, and most bountiful benefactor.

**RELIGIOUS**, in popish countries, is particularly used for a person engaged, by solemn vows, to the monastic life: or a person shut up in a monastery to lead a life of devotion and austerity, under some rule or institution. See the articles **MONK**, **NUN**, &c.

**REMAINDER**, in law, is an estate in lands, tenements, or rents, not to be enjoyed till after a term of years, or another person's decease: thus, a person grants lands or tenements to one person for a term of years, or for life, and the remainder to another person for life, or in fee.

**REMAINDER**, in mathematics, is what is left after taking a lesser number out of a greater.

**REMINISCENCE**, *Reminiscencia*, that power of the human mind, whereby it recollects itself, or calls again into its remembrance such ideas or notions as it had really forgot: in which it differs from memory, which is a treasuring up of things in the mind, and keeping them there without forgetting them. See the article **MEMORY**.

**REMISSION**, in physics, the abatement of the power or efficacy of any quality, in opposition to the increase of the same, which is called intension. In all qualities, capable of intension and remission, the intension decreases reciprocally as the squares of distances from the center of the radiating quality increase.

**REMISSION**, in medicine, is when a distemper abates, but does not go quite off before it returns again, as is common in fevers, which do not quite intermit.

**REMISSION**, in law, &c. denotes the pardon of a crime, or the giving up the punishment due thereto.

**REMITTANCE**, in commerce, the traffic or return of money from one place to another, by bills of exchange, orders, or the like.

This word is also used in speaking of the payment of a bill of exchange. It also signifies the fee or reward given a banker, both of his wages and the different value of the species in the places where you pay the money and where he remits it.

**REMITTER**, in law. Where a person has two titles to lands, &c. and he comes to such lands  
by

by the last title, which proving defective, he shall be restored to, and adjudged in, by virtue of his former more antient title, this is called remitter.

**REMONSTRANCE**, an expostulation or humble supplication, addressed to a king, or other superior, beseeching him to reflect on the inconveniences, or ill consequences of some order, edict, or the like.

This word is also used for an expostulatory counsel, or advice; or a gentle and handsome reproof, made either in general, or particular, to apprise or correct some fault, &c.

**REMORA**, the *SUCK-FISH*, in ichthyology, a singular fish which grows to about nine inches in length, and more than two in diameter in the largest part of the body, which is near the head, whence it becomes gradually smaller to the tail; the back is convex, the belly flat, and the sides are rounded by means of the structure of its head. This fish applies itself firmly to any solid body that it pleases; and is frequently found sticking to the bottom of ships, and often to large fish.

**REMOUNT**, in war. To remount the cavalry, is to furnish troopers or dragoons with fresh horses, instead of such as have been killed or disabled in the service.

**RENAL**, something belonging to the reins or kidneys. See the article **KIDNEY**.

**RENCOUNTER**, in the military art, an engagement of two little bodies or parties of forces; in which sense it stands in opposition to a pitched battle.

**RENCOUNTRE**, or **RENCONTRE**, in heraldry, is applied to animals when they shew the head in front, with both eyes, &c. or when the face stands right forward, as if they came to meet the person before them.

**RENDEZVOUS**, or **RENDEVOUS**, a place appointed to meet in, at a certain day and hour.

**RENEGATE**, or **RENEGADO**, a person who has apostatized or renounced the christian faith, to embrace some other religion, particularly mahometanism.

**RENIFORM**, something resembling the figure or shape of the kidneys. See the article **KIDNEY**.

**RENITENCY**, *Renitentia*, among philosophers, that force in solid bodies, whereby they resist the impulse of other bodies, or re-act as much as they are acted on. See the article **REACTION**, &c.

**RENT**, *Reditus*, in law, a sum of money, or other consideration, issuing yearly out of lands or tenements.

**RENTAL** signifies a roll in which the rents of manors are set down, in order for the lord's bailiff, thereby to collect the same. It contains the lands let to each tenant, with their names, and the several rents arising.

**RENUNCIATION**, *Renunciatio*, the act of re-

nouncing, abdicating, or relinquishing any right, real or pretended.

**REPAIRING**, or **REPARATION**, *Reparatio*, the act of retrieving, mending, or establishing a building or other work damaged or gone to decay. In respect to reparations, if a tenant or lessee covenants that from and after the amendment of the tenements by the lessor he will, at his own charge, keep and leave them in repair, in that case the lessee is not obliged to do the same until the lessor has first made good the reparations; and here if a house be well repaired at first, when the lease began, and afterwards decays, it is said the landlord must put it in repair before the tenant is bound to keep it so.

**REPARTEE**, or **REPARTY**, a ready smart reply, especially in matters of wit, humour, or raillery.

**REPARTITION**, a dividing or sharing a thing a second time.

**REPEALING**, in law, the revoking or annulling of a statute, or the like. See **ABROGATION** and **REVOCATION**.

**REPEAT**, in music, a character shewing that what was last played or sung must be repeated or gone over again.

**REPELLENTS**, in medicine, remedies which drive back a morbid humour into the mass of blood from which it was unduly secreted.

**REPERCUSSION**, in mechanics. See the article **REFLECTION**.

**REPERCUSSION**, in music, a frequent repetition of the same sound. See the article **REPETITION**.

**REPERTORY**, *Repertorium*, a place wherein things are orderly disposed, so as to be easily found when wanted. The indices of books are repertories, shewing where the matters sought for are treated of. Common-place books are also kinds of repertories.

**REPETITION**, *Repetitio*, the reiterating of an action.

**REPETITION**, in music, denotes a reiterating or playing over again the same part of a composition, whether it be a whole strain, part of a strain, or double strain, &c. The repetition is denoted by a character called a repeat, which is varied so as to express the various circumstances of a repeat. See **REPEAT**.

**REPETITION**, in rhetoric, a figure which gracefully and emphatically repeats either the same word, or the same sense in different words.

**REPLANTING**, in gardening, the act of planting a second time. See the article **PLANTING**.

**REPLETION**, in medicine, a plenitude or plethora. See **PLETHORA**.

Repletion is more dangerous than inanition. Bleeding and diet are the great resources whence a person is incommodeled with a repletion.

Repletion

Repletion is sometimes also used where the stomach is overloaded with too much eating or drinking. The physicians hold all repletion to be prejudicial, but that of bread is of all others the worst.

**REPLETION**, in the canon law, is where the revenue of a benefice or benefices is sufficient to fill or occupy the whole right or title of the graduate who holds them. Where there is a repletion, the party can demand no more by virtue of his degrees. In England, where benefices are not appropriated to degrees, repletion, strictly speaking, has no place.

**REPLEVIN**, in law, a remedy granted on a distress, by which the first possessor has his goods restored to him again, on his giving security, to the sheriff that he will pursue his action against the party distraining, and return the goods or cattle, if the taking them shall be adjudged lawful.

**REPLEVY**, in law, is a tenant's bringing a writ of replevin, or *replegiari facias*, where his goods are taken by distress for rent; which must be done within five days after the distress, otherwise at the five days end, they are to be appraised and sold. 2 W. and M. c. 5.

This word is also used for bailing a person, as in the case of a *homine replegiando*.

**REPLICATION**, in logic, the assuming or using the same term twice in the same proposition.

**REPORT**, the relation made upon oath, by officers or persons appointed to visit, examine, or estimate the state, expences, &c. of any thing.

**REPORT**, in law, is a public relation of cases judicially argued, debated, resolved, or adjudged in any of the king's courts of justice, with the causes and reasons of the same, as delivered by the judges.

**REPOSE**, in painting, certain masses or large assemblages of light and shade, which being well conducted, prevent the confusion of objects and figures, by engaging and fixing the eye so as it cannot attend to the other parts of the painting for some time; and thus leading it to consider the several groups gradually proceeding, as it were from stage to stage.

**REPOSITORY**, a stone house or place in which things are laid up and preserved.

In this sense we say, the repository of the royal society. See **MUSEUM**.

**REPRESENTATION**, in the drama, the exhibition of a theatrical piece, together with the scenes, machines, &c.

**REPRESENTATIVE**, one who personates or supplies the place of another, and is invested with his right and authority. Thus the house of commons are the representatives of the people in parliament. See **PARLIAMENT**.

**REPRIEVE**, or **REPRIVE**, in law is suspending or deferring the execution of the law upon a prisoner for a certain time; or a warrant from the

king for deferring the execution of a person condemned.

**REPRISALS**, a right which princes claim of taking from their enemies any thing equivalent to what they unjustly detain from them.

Reprisals is also used for a letter of marque granted by a prince to his subject. See the article **MARQUE**.

**REPRISE**, or **REPRIZE**, at sea, is a merchant-ship which, after its being taken by a corsair, privateer, or other enemy, is retaken by the opposite party.

**REPRIZES**, in law, are deductions or payments annually made out of a manor or lands; as rent-charges, pensions, annuities, &c.

**REPROBATION**, in theology, a decree by which God is supposed either from all eternity, or from the creation of the world, to consign over to eternal misery the greatest part of mankind, and to save none of the human race, except those whom he made the heirs of glory by election.

Casuists distinguish two kinds of reprobation, positive and negative. Positive reprobation, is that by which God is supposed to create men with a positive and absolute resolution to damn them eternally: and negative reprobation, is that whereby God, though he creates all men with a sincere desire to save them, and furnishes them with all the necessary means of salvation, so that all may be saved that will; yet sees there are several who will not do it, with the aids he shall afford them, and sees, at the same time, they would do it with certain other aids, which he sees, but will not give them.

**REPRODUCTION**, the act whereby a thing is produced anew, or grows a second time.

**REPTILES**, in natural history, a kind of animals denominated from their creeping or advancing on the belly. Or reptiles are a genus of animals and insects, which instead of feet, rest on one part of the body while they advance forward with the rest.

Such are earthworms, snakes, caterpillars, &c. Indeed most of the class of reptiles have feet; only those very small, and the legs remarkably short in proportion to the bulk of the body.

Naturalists observe a world of artful contrivance for the motion of reptiles. Thus, particularly in the earth-worm, Dr. Willis tells us, the whole body is only a chain of annular muscles; or, as Mr. Derham says, it is only one continued spiral muscle, the orbicular fibres whereof being contracted render each ring narrower and longer than before; by which means it is enabled, like the worm of an auger, to bore its passage into the earth. Its reptile motion might also be explained by a wire wound on a cylinder, which when slipped off, and one end extended and held fast, will bring the other near to it. So the earth-worm having shot out or extended his body (which is with a wreathing) it takes hold

by these small feet it hath, and so contracts the hinder part of its body. Dr. Tyson adds, that when the fore-part of the body is stretched out, and applied to a plane at a distance, the hind part relaxing and shortening is easily drawn towards it as a center.

Its feet are disposed in a quadruple row the whole length of the worm, with which, as with so many hooks, it fastens down sometimes this and sometimes that part of the body to the plane, and at the same time stretches out or drags after it another.

The creeping of serpents is effected after a somewhat different manner; there being a difference in their structure, in that these last have a compages of bones articulated together.

The body here is not drawn together, but as it were complicated; part of it being applied on the rough ground, and the rest ejaculated and shot from it, which, being set on the ground in its turn, brings the other after it. The spine of the back variously wreathed has the same effect in leaping, as the joints in the feet of other animals; they make their leaps by means of muscles, and extend the plicæ or folds.

**REPTILE**, is also used, by some botanical writers, to signify plants which creep upon the earth, unless sustained by some other plant, prop, &c. As the vine, cucumbers, melons, &c.

**REPUBLIC**, *Respublica*, commonwealth, a popular state or government; or a nation where the people have the government in their own hands.

**REPUBLIC of Letters**, a phrase used collectively of the whole body of the people of study and learning.

**REPUDIATION**, *Repudium*, in the civil law, the act of divorcing. See **DIVORCE**.

**REPULSION**, *Repulsio*, in physics, that property in bodies whereby, if they are placed just beyond the sphere of each other's attraction of cohesion, they mutually fly from each other.

Thus if an oily substance, lighter than water, be placed on the surface thereof, or if a piece of iron be laid upon mercury, the surface of the fluid will be depressed about the body laid on it: this depression is manifestly occasioned by a repelling power in the bodies, which hinders the approach of the fluid towards them. But it is possible, in some cases, to press or force the repelling bodies into the sphere of one another's attraction; and then they will mutually tend towards each other, as when we mix oil and water till they incorporate.

Dr. Knight defines repulsion to be that cause which makes bodies mutually endeavour to recede from each other, with different forces, at different times; and, that such a cause exists in nature, he thinks evident for the following reasons: 1. Because all bodies are electrical, or capable of being

made so; and it is well known, that electrical bodies both attract and repel. 2. Both attraction and repulsion are very conspicuous in all magnetical bodies. 3. Sir Isaac Newton has shewn from experiments, that the surfaces of two convex glasses repel each other. 4. The same great philosopher has explained the elasticity of the air, by supposing its particles mutually to repel each other. 5. The particles of light are, in part at least, repelled from the surfaces of all bodies. 6. Lastly, it seems highly probable, that the particles of light mutually repel each other, as well as the particles of air.

The same gentleman ascribes the cause of repulsion, as well as that of attraction, to the immediate effect of God's will; and as attraction and repulsion are contraries, and consequently cannot, at the same time, belong to the same substance, the doctor supposes there are in nature two kinds of matter, one attracting, the other repelling; and that those particles of matter which repel each other, are subject to the general law of attraction in respect of other matter.

A repellent matter being thus supposed, equally dispersed through the whole universe, the doctor attempts to account for many natural phenomena by means thereof. He thinks light is nothing but this repellent matter, put into violent vibrations by the repellent corpuscles which compose the atmosphere of the sun and stars; and that, therefore, we have no reason to believe they are gulphs of fire, but, like the rest of the heavenly bodies, inhabitable worlds.

From the same principles, he attempts to explain the nature of fire and heat, the various phenomena of the magnet, and the cause of the variation of the needle: and, indeed, it is difficult, if not impossible, by the doctrine of attraction alone, to account for all the phenomena observable in experiments made with magnets, which may now be solved by admitting this doctrine of a repellent fluid; but whether it will be sufficient to account for all the particular phenomena of nature, which are the proper tests of an hypothesis, time and experience alone must determine.

The doctor also endeavours to shew, that the attractions of cohesion, gravity, and magnetism, are the same, and that by these two active principles, viz. attraction and repulsion, all the phenomena of nature may be explained; but as his ingenious treatise on this subject is laid down in a series of propositions, all connected together, it would be impossible to do justice to his arguments, without transcribing the whole; we shall therefore refer the curious to the book itself.

According to 's Gravefande and others, when light is reflected from a polished spherical surface, the particles of light do not strike upon the solid parts, and so rebound from them; but are repelled from

from the surface, at a small distance before they touch it, by a power extended all over the said polished surface: and Sir Isaac Newton observes, that the rays of light are also expelled by the edges of bodies, as they pass near them; so as to make their shadows, in some cases, larger than they would otherwise be.

**REQUEST**, in law, a supplication or petition preferred to a prince, or to a court of justice, begging relief in some conscionable cases, where the common law grants no immediate redress.

*Court of REQUESTS*, an ancient court of equity, instituted about the nineteenth year of Henry VII.

**REQUIEM**, in the Romish church, a mass sung for the rest of the soul of a person deceased.

**RESCUIT**, *Receptio*, in law, an admission or receiving of a third person to plead his right, in a cause formerly commenced between the other two.

**RESCRIPT**, *Rescriptum*, an answer delivered by an emperor, or a pope, when consulted by particular persons, on some difficult question, or point of law, to serve as a decision thereof.

**RESEARCH**, a scrutiny, or diligent enquiry into any thing.

**RESEARCHING**, in sculpture, the repairing of a cast figure, &c. with proper tools; or the finishing it with art and exactness, so as the minutest parts may be well defined.

**RESEDA**, in botany, a genus of plants, whose flower-corolla consists of a few unequal petals, some of which are always semitrifid, with a plane, erect, nectarious glandule, produced from the receptacle: the stamina are fifteen or sixteen short filaments, topped with obtuse antheræ: the fruit is a gibbous and angulated capsule, containing one cell, which is filled with numerous kidney-shaped seeds.

**RESERVATION**, in law, an action or clause whereby something is reserved, or secured to one's self.

*Mental RESERVATION*, a proposition, which, strictly taken, and according to the natural import of the terms, is false; but, if qualified by something concealed in the mind, becomes true.

*Body of RESERVE*, or *Corps de RESERVE*, in military affairs, the third or last line of an army, drawn up for battle; so called, because they are reserved to sustain the rest, as occasion requires; and not to engage but in case of necessity.

**RESERVOIR**, a place where water is collected and reserved, in order to be conveyed to distant places through pipes, or supply a fountain, or jet d'eau.

**RESET**, in law, the receiving or harbouring an outlawed person. See **OUTLAWRY**.

**RESIDENCE**, in the canon and common law, the abode of a person, or incumbent, upon his benefice; and his assiduity in attending on the same.

**RESIDENT**, a public minister, who manages the affairs of a kingdom or state, at a foreign court.

They are a class of public ministers, inferior to ambassadors or envoys; but, like them, are under the protection of the law of nations.

**RESIDENTIARY**, *Residentarius*, a canon installed into the privileges and profits of residence.

**RESIDUAL FIGURE**, in geometry, the figure remaining after subtracting a lesser from a greater.

**RESIDUAL ROOT**, in algebra, a root composed of two parts or members, connected together by this sign,  $—$ . of  $x$  and  $y$ .

Thus  $x—y$  is a residual root, so called, because its value is no more than the difference between its parts  $x$  and  $y$ .

**RESIDUE**, *Residuum*, the remainder or balance of an account, debt, or obligation.

**RESIGNATION**, in the canon law, the surrendering a benefice into the hands of the collator, or bishop.

**RESIGNEE**, in law, the person to whom a thing is resigned.

**RESIN**, in natural history, a viscid juice, oozing either spontaneously, or by incision, from several trees, as the pine, fir, &c.

The resins of vegetables may be prepared nearly in the same manner as extracts, by using rectified spirit of wine instead of water: for such a spirit is the only proper menstruum that will dissolve the grosser resinous matter of vegetables, as water is of the mucilaginous and saline parts; yet these principles are so intimately combined in almost all plants, that whichever of these liquors is applied at first, it will take up a portion of what is directly soluble only in the other. Hence, sundry vegetables, extremely resinous, and whose virtues consist chiefly in their resin, afford, nevertheless, very useful extracts with water, though not equal to those obtained by a prudent application of spirit. See the article **EXTRACT**.

**RESISTANCE**, or **RESISTING FORCE**, in philosophy, denotes, in general, any power which acts in an opposite direction to another, so as to destroy or diminish its effect.

Hence the force wherewith bodies, moving in fluid mediums, are impeded or retarded, is the resistance of those fluids. See **FLUID**.

Authors have established it as a certain rule, that, whilst the same body moves in the same medium, it is always resisted in the duplicate proportion of its velocity; that is, if the resisted body move in one part of its track, with three times the velocity with which it moved in some other part, then its resistance to the greater velocity will be nine times the resistance to the lesser: if the velocity in one place be four times the velocity in another, the resistance to the greater velocity will be sixteen times the resistance to the lesser, and so on. This rule, though excessively erroneous, when taken in a general sense, is yet undoubtedly very near the truth, when confined within certain limits.

In order to conceive the resistance of fluids to a body moving in them, Mr. Robins distinguishes between those fluids, which being compressed by some incumbent weight, perpetually close up the space deserted by the body in motion, without permitting, for an instant, any vacuity to remain behind it; and those fluids in which, they being not sufficiently compressed, the space left behind the moving body remains for some time empty. These differences, in the resisting fluids, will occasion very remarkable varieties in the laws of their resistance, and are absolutely necessary to be considered in the determination of the action of the air in shot and shells; for the air partakes of both these affections, according to the different velocities of the projected body.

If a fluid was so constituted that all the particles composing it were at some distance from each other, and there was no action between them, then the resistance of a body moving therein, would be easily computed from the quantity of motion communicated to these particles: for instance, if a cylinder moved in such a fluid in the direction of its axis, it would communicate to the particles it met with a velocity equal to its own, and in its own direction, supposing that neither the cylinder, nor the parts of the fluid, were elastic; whence, if the velocity and diameter of the cylinder be known, and also the density of the fluid, there would thence be determined the quantity of motion communicated to the fluid, which (action and re-action being equal) is the same with the quantity lost by the cylinder, consequently the resistance would be hereby ascertained.

In this kind of discontinued fluid, the particles being detached from each other, every one of them can pursue its own motion in any direction, at least for some time; independent of the neighbouring ones; wherefore, if instead of a cylinder moving in the direction of its axis, a body, with a surface oblique to its direction, be supposed to move in such a fluid, the motion the parts of the fluid will hereby acquire, will not be in the direction of the resisted body, but perpendicular to its oblique surface; whence, the resistance to such a body will not be estimated from the whole motion communicated to the particles of the fluid, but from that part of it only, which is in the direction of the resisted body. In fluids then, where the parts are thus discontinued in each other, the different obliquities of that surface, which goes foremost, will occasion considerable changes in the resistance; although the section of the solid, by a plane perpendicular to its direction, should in all cases be the same. And Sir Isaac Newton has particularly determined, that in a fluid thus constituted, the resistance of a globe is but half the resistance of a cylinder of the same diameter, moving in the direction of its axis with the same velocity.

But though the hypothesis of a fluid, thus constituted, be of great use in explaining the nature of resistances; yet, in reality, no such fluid does exist within our knowledge: all the fluids with which we are conversant, are so formed, that their particles either lie contiguous to each other, or at least act on each other as if they did; consequently, in these fluids, no one particle, contiguous to the resisted body, can be moved, without moving at the same time a great number of others, some of which will be distant from it; and the motion thus communicated to a mass of the fluid will not be in any one determined direction, but will in each particle be different, according to the different manners in which it lies in contact with those, from which it receives its impulse; whence great numbers of the particles, being diverted into oblique directions, the resistance of the moving body, which will depend on the quantity of motion communicated to the fluid in its own direction, will be hereby different in quantity, from what it would be in the preceding supposition, and its estimation becomes much more complicated and operose.

Sir Isaac Newton, however, has determined, that the resistance to a cylinder, moving in the direction of its axis in such a compressed fluid as we have here treated of, is but one fourth part of the resistance, which the same cylinder would undergo, if it moved with the same velocity, in a fluid, constituted in the manner we have described in our first hypothesis, each fluid being supposed to be of the same density.

But, again, it is not only in the quantity of their resistance that these fluids differ, but likewise in the different manner in which they act on solids of different forms moving in them.

We have shewn, that in the discontinued fluid, which we first described, the obliquity of the foremost surface of the moving body would diminish the resistance; but in compressed fluids this holds not true, at least not in any considerable degree; for the principal resistance in compressed fluids arises from the greater or lesser facility, with which the fluid, impelled by the forepart of the body, can circulate towards its hinder part; and this being little, if at all, affected by the form of the moving body, whether it be cylindrical, conical, or spherical, it follows, that while the transverse section of the body, and consequently the quantity of impelled fluid is the same, the change of figure in the body will scarcely affect the quantity of its resistance.

The resistance of bodies of different figures, moving in one and the same medium, has been considered by Mr. J. Bernoulli in the *Acta Lipsiens.* for May, 1693; and the rules he lays down, on this subject, are the following: 1. If an isosceles triangle be moved in the fluid according to the direction of a line which is normal to its base; first with the vertex foremost, and then with its base; the resistances

ances will be as the legs, and as the square of the base, and as the sum of the legs. 2. The resistance of a square moved according to the direction of its side, and of its diagonal, is as the diagonal to the side. 3. The resistance of a circular segment (less than a semi-circle) carried in a direction perpendicular to its basis, when it goes with the base foremost, and when with its vertex foremost (the same direction and celerity continuing, which is all along supposed) is as the square of the diameter to the same, less one third of the square of the base of the segment.

Cor. Hence the resistances of a semi-circle, when its base, and when its vertex go foremost, are to one another in a sesquialterate ratio. 4. A parabola moving in the direction of its axis, with its basis, and then its vertex foremost, has its resistances, as the tangent to an arch of a circle, whose diameter is equal to the parameter, and the tangent equal to half the basis of the parabola. 5. The resistances of an hyperbola, or the semi-ellipsis, when the base and when the vertex go foremost, may be thus computed; let it be, as the sum, or difference, of the transverse axis, and latus rectum, is to the transverse axis, so is the square of the latus rectum to the square of the diameter of a certain circle; in which circle apply a tangent equal to half the basis of the hyperbola or ellipsis. Then say again, as the sum, or difference, of the axis and parameter is to the parameter, so is the aforesaid tangent to another right line. And further, as the sum, or difference, of the axis and parameter is to the axis, so is the circular arch, corresponding to the aforesaid tangent, to another arch. This done, the resistances will be as the tangent to the sum, or difference, of the right line thus found, and that arch last mentioned. 6. In general, the resistances of any figure whatsoever going now with its base foremost, and then with its vertex, are as the figures of the basis to the sum of all the cubes of the element of the basis divided by the squares of the elements of the curve line.

All which rules, he thinks, may be of use, in the fabric or construction of ships, and in perfecting the art of navigation universally. As also for determining the figures of the balls of pendulums for clocks. See the article SHIP, &c.

As to the resistance of the air, Mr. Robins, in his new principles of gunnery, took the following method to determine it: he charged a musket-barrel three times successively with a leaden ball  $\frac{3}{4}$  of an inch diameter, and took such precaution in the weighing of the powder, and placing it, as to be sure, by many previous trials, that the velocity of the ball could not differ by 20 feet in 1" from its medium quantity. He then fired it against a pendulum, placed at 25, 75, and 125 feet distance, &c. from the mouth of the piece respectively. In the first case it impinged against the pendulum with

a velocity of 1670 feet in 1"; in the second case with a velocity of 1550 feet in 1"; and in the third case with a velocity of 1425 feet in 1"; so that in passing through 50 feet of air, the bullet lost a velocity of about 120, or 125 feet in 1"; and the time of its passing through that space being about  $\frac{3}{2}$  or  $\frac{4}{3}$  of 1", the medium quantity of resistance must, in these instances, have been about 120 times the weight of the ball; which, as the ball was nearly  $\frac{1}{12}$  of a pound, amounts to about 10 lb. avoirdupoise.

Now if a computation be made, according to the method laid down for compressed fluids in the 38th proposition of lib. 2. of Sir Isaac Newton's Principia, supposing the weight of water to be to that of air, as 850 to 1, it will be found that the resistance of a globe of three quarters of an inch diameter, moving with a velocity of about 1600 feet in 1", will not, on those principles, amount to any more than a force of  $4\frac{1}{6}$  lb. avoirdupoise; whence we may conclude (as the rules in that proposition for slow motions are very accurate) that the resisting power of the air in slow motions is less than in swift motions, in the ratio of  $4\frac{1}{6}$  to 10, a proportion between that of 1 to 2, and 1 to 3.

Again, charging the same piece with equal quantities of powder, and balls of the same weight, and firing three times at the pendulum, placed at 25 feet distance from the mouth of the piece, the medium of the velocities with which the ball impinged was 1690 feet in 1". Then removing the piece 175 feet from the pendulum, the velocity of the ball, at a medium of five shots, was 1300 feet in 1". Whence the ball, in passing through 150 feet of air, lost a velocity of about 390 feet in 1"; and the resistance computed from these numbers, comes out something more than in the preceding instance, amounting to between 11 and 12 pounds avoirdupoise: whence, according to these experiments, the resisting power of the air to swift motions is greater than in slow ones, in a ratio which approaches nearer to the ratio of 3 to 1, than in the preceding experiments.

Having thus ascertained the resistance to a velocity of near 1700 feet in 1", he next proceeded to examine this resistance in smaller velocities: the pendulum being placed at 25 feet distance, was fired at five times, and the mean velocity with which the ball impinged was 1180 feet in 1". Then removing the pendulum to the distance of 250 feet, the medium velocity of five shot at this distance, was 950 feet in 1"; whence the ball, in passing through 225 feet of air, lost a velocity of 230 feet in 1", and as it passed through that interval in about  $\frac{3}{4}$  of 1", the resistance to the middle velocity will come out to be near  $33\frac{1}{2}$  times the gravity of the ball, or 2 lb. 10 oz. avoirdupoise. Now the resistance to the same velocity, according to the laws observed in slower motions, amounts to  $\frac{1}{17}$  of the same

same quantity; whence in a velocity of 1065 feet in 1", (the medium of 1180 and 950) the resisting power of the air is augmented in no greater proportion than of 11 to 7; whereas in greater degrees of velocity, as before, it amounted very near to the ratio of 3 to 1.

That this resisting power of the air to swift motions, is very sensibly increased beyond what Sir Isaac's theory for slow motions makes it, seems hence to be evident. It being, as has been said, in musket, or cannon shot, with their full charge of powder, near three times the quantity assigned by that theory.

The resistance of a bullet of three quarters of an inch diameter, moving in air with a velocity of 1670 feet in 1", amounting, as we said, to 10lb. the resistance of a cannon ball of 24 lb. fired with its full charge of powder, and thereby moving with a velocity of 1650 feet in 1", may hence be determined. For the velocity of the cannon ball being near the same as the musket bullet, and its surface above 54 times greater, it follows, that the resistance on the cannon ball will amount to more than 540lb. which is near 23 times its own weight. And from hence it appears how rash and erroneous the opinion of those is, who neglect the consideration of the resistance of the air as of no importance in the doctrine of projectiles. See the articles PROJECTILE and GUNNERY.

RESISTANCE of the fibres of solid bodies is more properly called cohesion. See the article COHESION.

RESOLUTION, in chemistry, &c. the reduction of a mixed body into its component parts, or first principles, by a proper analysis.

RESOLUTION, in medicine, that coction or alteration of the crude peccant matter of any disease, either by the natural strength of the patient, or of its own accord, or by the application of remedies, whereby its bulk, figure, cohesion, &c. are so far changed, as that it ceases to be morbid, and becomes laudable.

RESOLVENTS, *Resolventia*, in medicine, remedies proper to resolve and dissipate tumours and gatherings, to soften indurations, and, by their tenuity and warmth, evacuate redundant or peccant humours through the pores. Under this class come various unguents, emplasters, &c.

RESONANCE, *resounding*, in music, &c. a sound returned by the air, inclosed in the bodies of stringed musical instruments, as lutes, &c. or even in the bodies of wind instruments, as flutes, &c. See SOUND and MUSIC.

RRSPIRATION, *Respiratio*, the act of respiring, or breathing the air. What respiration is, and why it is uninterruptedly carried on without the concurrence of the mind, will appear from the following considerations of Boerhaave. The lungs suspended in the air, which every where acts upon

them, and equally presses them always, collapse, contract themselves into a smaller space, and become much less than when they remained in the intire thorax. This is principally performed by the contractile force of the muscular fibres, which connect the squamous segments of the bronchia. If the lungs thus contracted, are filled with air, forcibly blown through the glottis, they are so distended as in bulk not only to equal that which they had in the intire thorax, but even to exceed it; all which is sufficiently certain from experiments. The same thing happens if, when an access for the air through the glottis is left to the lungs, the air externally acting on the lungs, is either removed, or its pressure diminished. Hence it is obvious, that the lungs, by their proper force, have always a tendency to become less in all their parts than they are when placed in the intire thorax. For this reason, it is certain that they are in a continual state of distraction so long as a person is alive, so that they must collapse, and be diminished, whilst the whole of the animal remains in a vacuum, obtained by an exhaustion of the air in an air-pump. For there is nothing similar to a circumbient air between the external membrane of the lungs, and all the internal surface of the pleura in a sound person; nothing therefore externally compresses the lungs, except the diaphragm. There is, however, always an internal air contained in them, and freely conveyed to them through the glottis. Hence the lungs are always somewhat more distended by the internal, than they are compressed by the external, air, the access of which is hindered by the diaphragm, which is so connected with the ribs and vertebræ, that the air cannot enter the thorax in such a manner as would be requisite for an equilibrium.

RESPITE, in law, &c. signifies a delay, forbearance, or prolongation of time, granted any one, for the payment of a debt, or the like.

RESPONDENT SUPERIOR, in law, is a superior's answering for the insufficiency of an inferior. Thus, if the sheriffs of London are insufficient, the lord-mayor and commonalty must answer for them, as the sheriffs superior.

RESPONDENT, in the schools, one who maintains a thesis, in any art or science; who is thus called, from his being to answer all the objections proposed by the opponent.

RESPONDENT, in law, a person who undertakes to answer for another; and also, one who binds himself as a security for another person's good behaviour.

RESSAULT, in architecture, is the effect of a body which either projects or sinks back; that is, stands more out or in, than another, so as to be out of the line or level with it.

REST, *Quies*, the continuance of a body in the same place, or its continual application or contiguity to the same parts of the ambient or contiguous

## RES

guous bodies; and, therefore is opposed to motion. See the article **MOTION**.

Sir Isaac Newton defines true or absolute rest, to be the continuance of a body in the same part of absolute space; and relative rest to be the continuance of a body in the same part of relative space. See the article **SPACE**.

It is one of the laws of nature, that matter is indifferent to motion or rest, as has been shewn under the article **INERTIA**.

Rest considered in a physical view, is only salutary, in so far as it is duly proportioned to the exercise; for a sedentary idle life brings on many indispositions. See the article **EXERCISE**.

**REST**, in poetry, is a short pause of the voice, in reading, being the same with the cæsura, which, in Alexandrine verses, falls on the sixth syllable; but in verses of ten or eleven syllables, on the fourth.

**REST**, in music, the same with pause. See the article **PAUSE**.

**RESTIVE**, or **RESTY**, in the manege, a stubborn, unruly, ill-broken horse, that stops, or runs back, instead of advancing forward.

**RESTORATIVE**, in medicine, a remedy proper for restoring and retrieving the strength and vigour both of the body and animal spirits.

**RESTRICTION**, among logicians, is limiting a term, so as to make it signify less than it usually does.

**RESULT**, what is gathered from a conference, inquiry, meditation, or the like; or the conclusion and effect thereof.

**RESURRECTION**, in theology, rising again from the dead; or a person's returning to a second life, with new bodily organs, adapted to the state of its new existence.

One of the greatest arguments for the truth of christianity is drawn from the resurrection of our Saviour; the circumstances of which are handed down to us in so plain and distinct a manner, by the evangelists, as make the evidence of this important truth amount to a demonstration.

Christians generally believe, that at the day of judgment, the very identical body they have now, with the same flesh, blood, and bones, will be raised from the dead. But, in opposition to this opinion, many texts of scripture have been urged, particularly the account given of this important event by St. Paul; besides several philosophical objections, the principal of which are these.

That the same substance may happen to be a part of two or more bodies: thus a fish feeding on a man, and another man afterwards feeding on the fish, part of the body of the first man becomes incorporated with the fish, and afterwards with the body of the last man. Again, instances have been known of one man's immediately feeding on the body of another; and among the Cannibals in the

## RET

West-Indies, who devour their enemies, the practice is frequent. Now it is alledged, where the substance of one is thus converted into the substance of another, each cannot arise with his whole body; to which then shall the common part be allotted?

To this objection some answer, that as all matter is not capable of being assimilated to the body, and incorporated with it, human flesh may very probably be of this kind; and, therefore, what is thus eaten, may be again excreted and carried off.

But Mr. Leibnitz observes, that all that is essential to the body, is the original stamen, which existed in the semen of the father: this may be conceived as the most minute point imaginable, and therefore not to be separated, nor any part of it united to the stamen of any other man. That all this bulk we see in the body, is only an accretion to this original stamen; and therefore there is no reciprocation of the proper matter of the human body.

Another objection is, that we know, by the late discoveries in the animal economy, that the human body is continually changing, and that a man has not entirely the same body to-day, as he had yesterday; and it is even computed that in less than seven years time, the whole body undergoes a change. Which of those many bodies then, which the same person has in the course of his life, is it that shall rise? or does all the matter that has ever belonged to him, rise again? or does only some particular system thereof? the body, for example, he had at twenty, at forty, or at sixty years old? If only this or that body arise, how shall it be rewarded or punished for what was done by the other? and with what justice does one person suffer for another?

To this it has been answered on the principles of Leibnitz, that notwithstanding these successive changes, this stamen, which is the only essential part of the body, has always remained the same; and that on Mr. Locke's principles, personal identity, or the sameness of a rational being, consists in self-consciousness, in the power of considering itself the same thing in different times and places. By this, every one is to himself what he calls self; without considering whether that self be continued in the same or in several substances. It is the same self now, it was then; and it was by the same self which now reflects on an action, that action was performed. Now it is this personal identity that is the object of rewards and punishments, which, it is observed may exist in different successions of matter; so that to render the rewards and punishments just and pertinent, we need only to rise again with such a body as that we retain the consciousness of our past actions.

**RETAIL**, in commerce, is the selling of goods in small parcels, in opposition to wholesale. See the article **COMMERCE**.

**RETAINER**,

**RETAINER**, in law, a servant who does not continually dwell in the house of his master, but only attends upon special occasions.

**RETAINING FEE**, the first fee given to a serjeant or counsellor at law, in order to make him sure, and prevent his pleading on the contrary side.

**RETARDATION**, in physics, the act of diminishing the velocity of a moving body. See the article **MOTION**.

If bodies of equal bulk, but of different densities, be moved through the same resisting medium, with equal velocity, the medium will act equally on each, so that they will have equal resistances; but their motions will be unequally retarded, in proportion to their densities. See the articles **RESISTANCE**.

Retarded motion from gravity is peculiar to bodies projected upwards, and this in the same manner as a falling body is accelerated; only in the latter, the force of gravity acts in the same direction with the motion of the body; and in the former in an opposite direction. See the article **ACCELERATION**.

As it is the same force which augments the motion in the falling, and diminishes it in the rising body, a body will rise till it has lost all its motion; which it does in the same time wherein a body falling would have acquired a velocity equal to that where with the body was projected upwards.

**RETE MIRABILE**, in anatomy, a small plexus, or net-work of vessels in the brain, surrounding the pituitary gland.

The rete mirabile is very conspicuous in brutes, but either not existent in man, or so very minute that its existence is fairly doubted. See the article **BRAIN**.

**RETENTION**, is defined by Mr. Locke, to be a faculty of the mind, whereby it keeps or retains those simple ideas it has once received, by sensation or reflection.

**RETENTION** is also used, in medicine, &c. for the state of contraction in the solids or vascular parts of the body, which makes them hold fast their proper contents.

**RETICULAR BODY**, *Corpus Reticulare*, in anatomy, a very fine membrane, perforated, in the manner of a net, with a multitude of foramina. It is placed immediately under the cuticle, and when that is separated from the cutis, whether by art or by accident, this adheres firmly to it, and is scarce possible to be parted from it, seeming rather to be its inner superficies than a distinct substance. In regard to this, we are to observe, first, the places in which it is found, being all those in which the sense of feeling is most acute, as in the palms of the hands, the extremities of the fingers, and on the soles of the feet. The tongue, however, is the part where it is most accurately to be observed: it is more easily distinguishable there than any where

else, and its nature and structure are most evidently seen there.

Its colour in the Europeans is white, but in the Negroes, and other black nations, it is black; in the tawney it is yellowish: the skin itself in both is white; and the blackness and yellowness depend altogether on the colour of this membrane.

The uses of the corpus reticulare are to preserve the structure of the other parts of the integuments, and keep them in their determinate form and situation. Its apertures give passage to the hairs, and let through the papillæ and excretory ducts of the skin: it retains these in a certain and determinate order, that they cannot be removed out of their places, and has some share in preserving the softness of the papillæ, which renders them fit for the sense of feeling.

**RETICULAR PLEXUS**, *Plexus Reticularis*, sometimes denotes the choroides, which is thus called because its fibres are interwoven like a net. See **CHOROIDES**.

**RETICULUM**, the caul or omentum, a name sometimes given to this part, from its net-like structure. See the article **OMENTUM**.

**RETINA**, in anatomy, the expansion of the optic nerve on the internal surface of the eye, whereupon the images of objects being painted, are impressed, and by that means conveyed to the common sensory in the brain, where the mind views and contemplates their ideas.

**RETRADE**, in fortification, a kind of retrenchment made in the body of a bastion, or other work, which is to be disputed inch by inch, after the defences are dismantled. It usually consists of two faces, which make a re-entering angle. When a breach is made in a bastion, the enemy may also make a retrade or new fortification behind it.

**RETRACTION**, *Retractio*, the act of drawing back, or unsaying what a person had said before.

Among anatomists, retraction frequently signifies the contraction or shortening of any part.

**RETRACTS**, among horsemen, pricks in a horse's feet, arising from the fault of the farrier in driving nails that are weak, or in driving them ill pointed, or otherwise amiss.

**RETRAHENS Auriculam**, in anatomy, a muscle of the external ear, consisting of a parcel of fleshy fibres, which in some bodies are divided into three distinct muscles arising from the os temporale, and fixed to the hind part of the concha. But these muscles are so small in men, that the auricle is seldom moveable at all.

**RETREAT**, in war, the retiring or moving back again of any army or part thereof.

**RETREAT**, or **RELAY**, in masonry, a little recess or diminution of the thickness of a wall, rampart, &c. in proportion as it is raised. The retreat, properly, is the diminution of a wall with-  
outside,

outside, or the contraction of its upper courses more than the foundation. Where the foundation is very long, they usually make two or three retreats.

**RETRENCHMENT**, literally signifies something cut off or taken from a thing; in which sense it is the same with subtraction, diminution, &c.

**RETRENCHMENT**, in the art of war, any kind of work raised to cover a post, and fortify it against the enemy, such as fascines loaded with earth, gabions, barrels of earths, sand-bags, and generally all things that can cover the men and stop the enemy. But retrenchment is more particularly applicable to a foss bordered with a parapet; and a post fortified thus is called post retrenched, or strong post.

Retrenchments are either general or particular: general retrenchments are new fortifications made in a place besieged, to cover the besiegers when the enemy become masters of a lodgment on the fortification, that they may be in a condition of disputing the ground inch by inch, and of putting a stop to the enemy's progress in expectation of relief.

Particular retrenchments are such as are made in the bastions when the enemy are masters of the breach. These can never be made but in new full bastions, for in empty, or hollow ones, there can only be made retrades. The particular retrenchments are made several ways, according to the time they have to cover themselves: sometimes they are made before hand, which are certainly the best. The parapets of such retrenchments ought to be five or six feet thick, and five feet high, with a large and deep foss, from whence ought to run out small fougades and countermines.

**RETROGRADATION**, or **RETROGRESSION**, the act or effect of a thing moving backwards.

The retrograde motion of the planets is an apparent motion, whereby they seem, to an observer placed on the earth, to move backwards, or contrary to the signs. See **PLANET**, **ORBIT**, &c.

**RETROGRESSION of Curves**, their bending or turning backwards. See the articles **FLEXURE** and **INFLECTION**.

**RETROMINGENTS**, in natural history, a class or division of animals, whose characteristic it is that they stale, or make water backwards, both male and female.

**REVEILLE**, a beat of drum about break of day, to give notice that it is time for the soldiers to arise, and that the centries are to forbear challenging.

**REVELATION**, the act of revealing, or making a thing public that was before unknown: it is also used for the discoveries made by God to his prophets, and by them to the world; and more particularly for the books of the Old and New Testament.

The principal tests of the truth of any revelation are, its being worthy of God, and consistent with

his known attributes; its being agreeable to the clear dictates of unprejudiced reason; and its having a tendency to refine, purify, and exalt the mind of man to an imitation of the Deity in his moral perfections.

Mr. Locke, in laying down the distinct provinces of reason and faith, observes, 1. That the same truths may be discovered by revelation, which are discoverable to us by reason. 2. That no revelation can be admitted against the clear evidence of reason. 3. That there are many things of which we have but imperfect notions, or none at all; and others, of whose past, present, or future existence, by the natural use of our faculties we cannot have the least knowledge; and these, being beyond the discovery of our faculties, and above reason, when revealed, become the proper object of our faith. He then adds, that our reason is not injured or disturbed, but assisted and improved by new discoveries of truth coming from the fountain of knowledge. Whatever God has revealed is certainly true: but whether it be a divine revelation or no, reason must judge, which can never permit the mind to reject a greater evidence to embrace what is less evident. There can be no evidence that any traditional revelation is of divine original, in the words we receive it, and the sense we understand it, so clear and so certain, as that of the principles of reason: and, therefore, nothing that is contrary to the clear and self-evident dictates of reason, has a right to be urged or assented to as a matter of faith, wherein reason has nothing to do. Whatsoever is divine revelation ought to over-rule all our opinions, prejudices, and interests, and has a right to be received with full assent: and such a submission as this, of our reason to faith, takes not away the landmarks of knowledge.

**REVELATION of St. John**, the same with the **Apocalypse**. See **APOCALYPSE**.

**REVELS**, entertainments of dancing, masking, acting comedies, farces, &c. antiently very frequent in the inns of court, and in noblemen's houses, but now much disused. The officer who has the direction of the revels at court, is called the master of the revels.

**REVENUE**, the annual income a person receives from the rent of his lands, houses, interest of money in the stocks, &c.

**REVERBERATION**, *Reverberatio*, in physics, the act of a body repelling or reflecting another after its impinging thereon. See **REPULSION**.

**REVERBERATION**, in chemistry, denotes a kind of circulation of the flame by means of a reverberatory, or the return of the flame from the top of the furnace back to the bottom, chiefly used in calcination. Reverberation is of two kinds: the first with a close fire, that is, a reverberatory furnace, where the flame has no vent at top, being covered with a dome or capital, which repels its action back

back on the matter or the vessel that contains it, with increased vehemence. After this manner is refining, the distillation of acids, spirits, &c. performed. Reverberation with an open fire, is that performed in a furnace or reverberatory, whose registers are all open, used in calcination, &c. See the next article.

**REVERBERATORY**, or **REVERBERATING FURNACE**, a chemical furnace built close all around, and covered at the top with a capital of brick or tiles, so as not to give any vent to the heat or flame, but to determine it to reverberate or turn back from the brick-work with new force upon the matter placed at bottom.

When the fire has no vent or passage at top, it is a whole reverberatory. When the middle of the capital is open, and only the sides close, so that there is only a half circulation of the flame, it is called a half reverberatory.

The reverberatory furnace is chiefly used in the fusion and calcination of metals and minerals, and on other occasions where the most intense heat is required, as in assaying, &c. Whence it is also called the melting-furnace, and assaying-furnace.

**REVERIE**, the same with delirium, raving, or distraction. See **DELIRIUM**, &c.

It is used also for any ridiculous extravagant imagination, action, or proposition, a chimera or vision. But the most ordinary use of the word, among English writers, is for a deep disorderly musing or meditation.

**REVERSION**, *Reversio*, in law, is defined to be returning of lands, &c. into the possession of the donor, or his heirs.

Reversion, in the law of England, has two significations; the one of which is an estate left, which continues during a particular estate in being; and the other is the returning of the land, &c. after the particular estate is ended; and it is farther said, to be an interest in lands, when the possession of it fails, or where the estate, which was for a time parted with, returns to the grantors, or their heirs. But, according to the usual definition of a reversion, it is the residue of an estate left in the grantor, after a particular estate granted away ceases, continuing in the grantor of such an estate.

The difference between a remainder and a reversion, consists in this, that the remainder may belong to any man except the grantor; whereas the reversion returns to him who conveyed the lands, &c. See the article **REMAINDER**.

**REVIEW**, in war, is the appearance of an army, or part of an army, in order of battle, and their being viewed by the general, that he may know the condition of the troops, see that they are complete, and be a witness of the expertness with which they perform their evolutions, and other exercises.

**REVISE**, among printers, a second or third

proof of a sheet to be printed, taken off in order to be compared with the last proof, to see whether all the mistakes marked in it are corrected. See the article **PRINTING**.

**REVULSION**, in medicine, turning a flux of humours from one part to another, by bleeding, cupping, frictions, sinapisms, blisters, fomentations, bathings, issues, setons, strong purging of the bowels, &c.

Dr. Van Sweiten, in his Commentaries upon the Aphorisms of Boerhaave, observes, that the use of revulsions in diseases, is confirmed by daily experience as well as by reason; for so soon as the resistance to the blood's motion is either diminished or totally removed in any part of the body, it immediately flows into that part with a greater velocity.

Thus, when all the vessels and viscera of the abdomen are suddenly freed from a considerable pressure by the birth of an infant, all the blood is frequently derived into those vessels so forcibly, that unless the fluid vessels and viscera are compressed by swathing with a roller, the child-bed woman may suddenly perish in a fatal swoon, for want of the blood's due pressure in the vessels of the brain and cerebellum: the same thing also happens if the abdomen is not swathed, when all the water is discharged at once by paracentesis, in the dropsy.

If, again, we consider, that the blood propelled by the heart is sent partly up to the head, and superior parts of the trunk, and partly downward to the viscera and lower extremities, it will be from hence evident, that, by diminishing the resistance of the lower vessels, or by evacuating them, the quantity and impulse of the blood will then be derived more towards the inferior parts, and drawn from those that are superior. It is therefore possible, to make a revulsion of the arterial blood from an inflamed part to any other, especially when the part, towards which the revulsion is made, receives its blood from the same common trunks or larger arteries.

The physicians foment the external parts of the head in inflammatory disorders thereof, that the impulse of the blood, being increased in the branches of the external carotide, may press with a less force upon the parts contained in the head. And Galen has long ago observed, that pains are eased almost as with a charm, by making a revulsion with cupping-glasses.

**RHABARBARUM**, rhubarb, in botany. See **RHUBARB**.

**RHACOMA**, in botany, a genus of plants, the corolla of which is divided into four fimbriated, roundish, patent segments: the stamina are four subulated filaments, topped with roundish antheræ; and the fruit is a roundish unilocular capsule, containing one seed of the same form.

**RHAGADIOLUS**, in botany, the same with lapsana. See the article **LAPSANA**.

**RHAGOIDES**, in anatomy, the second coat or

tuic of the eye, more usually called uvea. See the article UVEA.

RHAMNOIDES, in botany, Tournefort's name for the hippophae. See HIPPOPHAE.

RHAMNUS, the buckthorn, in botany. See BUCKTHORN.

RHAPHONTICOIDES and RHAPHONTICUM, the same with the centauria. See the article CENTAURIA.

RHAPHONTICUM, is also the name for the root of the rheum. See the article RHEUM.

RHAPSODI, *ῥαψῳδοί*, *Rhapsodists*, in antiquity, persons who made a business of singing pieces of Homer's poems.

Cuper informs us, that the Rhapsodi were clothed in red, when they sung the Iliad, and in blue, when they sung the Odyssey. They performed on the theatres, and sometimes strove for prizes in contests of poetry, singing, &c. After the two antagonists had finished their parts, the two pieces or papers they were written in, were joined together again; whence the name, viz. from *ῥαπτω*, *suo*, and *ωδῆ*, *canticum*.

But there seems to have been other Rhapsodi, of more antiquity than these people, who composed heroic poems or songs in praise of heroes and great men, and sung their own compositions from town to town, for a livelihood; of which profession, Homer himself is said to be.

RHAPSODY, *ῥαψῳδία*, in antiquity, a discourse in verse, sung or rehearsed by a rhapsodist.

Others will have rhapsody to signify a collection of verses, especially those of Homer, which having been a long time dispersed in pieces and fragments, were at length, by Pisistratus's order, digested into books called rhapsodies, from *ῥαπτω*, *suo*, and *ωδῆ*, *canticum*. Hence, among moderns, rhapsody is also used for an assemblage of passages, thoughts, and authorities raked together from divers authors, to compose some new piece.

RHEEJA, in botany, a genus of plants, whose flower consists of four concave, oval, patent petals, with a number of filaments. The fruit is ovate, small, succulent, and unilocular, and contains three ovato-oblong seeds.

RHETORIANS, a sect of heretics in Egypt, so denominated from Rhetorius their leader. The distinguishing doctrine of this heresiarch, as represented by Philastrius, was, that he approved of all the heresies before him, and taught that they were all in the right.

RHETORIC, *Rhetorica*, the art of speaking copiously on any subject, with all the advantage of beauty and force.

Lord Bacon defines rhetoric very philosophically, to be the art of applying and addressing the dictates of reason to the fancy, and of recommending them there-so as to affect the will and desires. The end of rhetoric, the same author observes, is to fill the

imagination with ideas and images which may assist nature without oppressing it. Vossius defines rhetoric, the faculty of discovering what every subject affords of use for persuasion. Hence, as every author must invent arguments to make his subject prevail, dispose those arguments, thus found out, in their proper places, and give them the embellishments of language proper to the subject; and if this discourse be intended to be delivered in public, utter them with that decency and force which may strike the hearer; rhetoric becomes divided into four parts, invention, disposition, elocution, and pronunciation.

Rhetoric and oratory differ from each other as the theory from the practice; the rhetorician being he who describes the rules of eloquence, and the orator he who uses them to advantage. Ordinarily, however, the two are used indifferently for each other.

RHEUM, *ρευμα*, a thin serous humour, occasionally oozing out of the glands about the mouth and throat.

RHEUM, the rhubarb, in botany. See the article RHUBARB.

RHEUMATISM, in medicine, a distemper that happens most commonly in spring or autumn, when there is a remarkable change of air from hot to cold, and from cold to hot, or when the wind suddenly shifts to any opposite point. It begins, according to Sydenham, with a shivering and other symptoms of a fever; and in a day or two's time, or sometimes sooner, a vehement pain seizes one or more of the limbs, raging sometimes in one place and sometimes in another, especially in the arms, wrists, shoulders, and knees: very often there is a redness and swelling, and the fever gradually goes off while the pain remains. This distemper often runs out into a great length, continuing sometimes for some months or years, not perpetually, with the same violence, but coming and going, and from time renewing its paroxysms.

It chiefly attacks persons in the flower of their age, after violent exercise, or a great heat of the body from any other cause, and then being too suddenly cooled. Its proximate cause Boerhaave takes to be an inflammation of the lymphatic arteries of the membranes near the ligaments of the joints, but not so violent as to bring on a suppuration. This disease is nearly a-kin to the gout and scurvy, and the blood is like that of those afflicted with the pleurisy. The pain is exasperated upon the least motion; it sometimes attacks the loins and coxendix, and sometimes the brain, lungs, and viscera: when it seizes the loins it is then called lumbago: in this case, Sydenham observes that there is a most violent pain in the small of the back, which sometimes extends to the os sacrum, and is like a fit of the gravel, only the patient does not vomit. If this disease is unskilfully treated, it may continue several

veral months or years, but not always with the same violence, but by fits. If it continues and encreases, it may cause a stiff joint, which will scarce yield to any remedy.

Sydenham directs to take away ten ounces of blood on the side affected; this must be repeated three or four times or oftener, once every other or every third day, according as the strength of the patient will bear. The diet must be very thin, and an emulsion of the four cold seeds may be given; as also a pultice of white-bread and milk, tinged with a little saffron, may be laid to the part affected: a clyster of milk and sugar may be injected on those days the bleeding is omitted. If the patient cannot bear frequent bleeding, after the second or third time, give the common purging potion every other day, and an ounce of diacodium at night, till he recovers.

In an incipient rheumatism of the shoulders, Hoffman says that nothing is better than a blister laid between the scapulæ; but if it happens to the plethoric, cupping, with scarification in the lower parts, repeated every month, does signal service. The same physician thinks it may be proper to chew rhubarb, from two scruples to a dram, with raisins or currants, two or three times a week.

The spirit of hartsorn and the balsam of guaiacum, given in the quantity of twenty or thirty drops, three or four times a day, Dr. Shaw says, is of great service: but he thinks nothing better than a decoction of the sudorific woods, to the quantity of a quart a day, for a month or six weeks together. This last, when assisted with crude antimony and mercurius dulcis, Hoffman recommends in the venereal rheumatism, which often arises from the remains of a lues venerea contained in the mass of blood. In a scorbutic rheumatism, or that arising from the scurvy, Sydenham directs the patient to take the scorbutic electuary and water, if he cannot bear any kind of evacuation.

He observes, that young persons who live temperately may be cured by a simple refrigerating diet, and moderate nourishing, with as much certainty as by repeated bleeding: for instance let the patient live four days upon whey alone; and after that white bread may be allowed for dinner, and on the last day of his illness he may be allowed it for supper. When the symptoms cease, he may have boiled chickens, or any thing of easy digestion, but every third day he must live upon whey only, till his strength returns. Boerhaave's method of cure is to the same effect, only he advises warm baths and strong blisters to be laid on the part affected, nay even cauteries themselves: but Hoffman observes that great caution should be used with regard to topics, for if the patient's constitution is sanguineous they should all be avoided, and the part covered carefully with the bed-cloaths; but if there is a thick, cold, stagnating humour in the part, and a

sense of cold, with a stricture of the pores, then frictions may be used with rough warm cloths, and afterwards cupping with scarifications. If the part becomes stiff and inflexible, with a numbness, which is called a paresis, then take human or canine axungia, two ounces; balsum of Peru, and oil of cloves, each two drams; with which make a liniment for the part: this has been known to have a wonderful effect. Arbuthnot says, that cream of tartar in water-gruel, taken for several days will abate the pains and swellings considerably by its acidity, correcting the alkaline salts of the blood.

Cheyne says, that the hot and inflammatory rheumatisms have all the symptoms of the gout, and, like it, change from place to place, and by over violent evacuations may be translated upon the noble organs.

**RHEXIA**, in botany, a genus of plants, whose flower consists of four roundish patent petals, inserted into the cup: the stamina are eight filiform filaments, terminated with narrow, obtuse, declining, furrowed antheræ: the fruit is a roundish capsule, formed of four valves, containing four cells, and inclosed in the belly of the cup: the seeds are roundish and numerous.

**RHINANTHUS**, rattle, in botany, a genus of plants, whose flower is monopetalous and ringent; the tube is almost cylindric, and the length of the cup; the limb is opening and compressed at the base; the upper lip is galeated, compressed, emarginated, and narrow; and the lower lip is plane, spreading, and cut into three obtuse parts at the extremity, the middle one being broader: the stamina are four filaments, two of which are shorter than the others, and terminated with hairy incumbent antheræ: the fruit is an obtuse, erect, compressed capsule, with two cells, containing many compressed seeds.

The seeds and capsules of a species of this genus, called *Semen Savadillos*, boiled in water, effectually destroy vermin, particularly bugs, the parts where they harbour being washed therewith.

**RHINOCEROS**, in zoology, an order of the jumenta, having eleven fore-teeth in each jaw; there are no canine teeth; the nose is ornamented with a single or double horn, which is permanent. This, of all quadrupeds, approaches nearest to the elephant in size, the body being nearly as bulky, but the legs much shorter. A full grown rhinoceros is fourteen feet high, and the legs are so short with all this height, that the belly comes near the ground: the head is very large and oblong, of an irregular figure, broad at top and depressed towards the snout: the ears resemble those of a hog: the eyes are very small, and situated at a small distance from the extremity of the snout: on the upper part of the snout, near the extremity, stands the horn, growing to about two feet and a half in length, bent a little back, of a black colour, and vastly firm and hard: the skin is remarkably thick and hard, so that:

that the creature could not turn his body in any direction but for the joints and folds in it: the tail is short, and furnished with some long and extremely thick black hairs.

**RHIZOPHORA**, in botany, a genus of aquatic plants, whose flower consists of four oblong petals, almost the length of the cup, with scarce any filaments, and small acuminate antheræ: the fruit is fleshy, and almost egg-shaped, containing one seed, which is of an oblong acuminate figure.

This genus is the Mangles of Plumier, and is called Mangrove by the inhabitants of the West-Indies.

**RHODIOLA**, in botany, a genus producing male and female flowers on different plants; the male flower consists of four oblong, obtuse, deciduous petals, with four erect emarginated nectaria, and eight subulated stamina; the female flower hath four erect, obtuse, persistent petals, with the nectaria the same as the male: the fruit consists of four corniculated capsules, opening inwards, and contains a great many roundish seeds.

**RHODIUM LIGNUM**, **RHODIAN-WOOD**, in botany, the same with aspalathum. See the article **ASPALATH**.

**RHODODENDRUM**, in botany, a genus of plants, whose flower is monopetalous and of a rotated funnel-shaped figure; the stamina are ten slender filaments, topped with oval antheræ; the fruit is a subangulated oval capsule, having five cells, which contain a great number of very small seeds.

**RHODORA**, in botany, a genus of plants, whose flower consists of three petals; the upper ones of which are equal and lanceolated, and the other is concave and less; the stamina are ten slender declining filaments, terminated with roundish twin antheræ; the fruit is an ovate capsule, having five cells, which contain a great number of minute seeds.

**RHODON**, in pharmacy, an appellation given to several compositions, on account of roses being the chief ingredient in them; as the diarrhodon, rhodofaccharum, &c.

**RHOMBOIDES**, in geometry, a quadrilateral figure whose opposite sides and angles are equal, but is neither equilateral nor equiangular.

**RHOMBOIDES**, in anatomy, a thin, broad, and obliquely square fleshy muscle, situated between the basis of the scapula and the spina dorsi; so called from its figure. Its general use is to draw, backward and upward, the subspinal portion of the basis scapulæ.

**RHOMBUS**, in geometry, an oblique-angled parallelogram, or a quadrilateral figure whose sides are equal and parallel, but the angles unequal, two of the opposite ones being obtuse, and the other two acute.

**RHOPHALIC VERSES**, in antient poetry, a

kind of verses, which beginning with monosyllables, were continued in words growing gradually longer and longer to the last.

**RHUBARB**, *Rheum*, in botany, a plant whose flower is monopetalous, narrow at the base, and impervious, with the limb divided into six obtuse segments, which are alternately smaller; the stamina are nine capillary filaments, inserted in the corolla, and terminated with oblong, blunt, and twin antheræ: there is no pericarpium; the seed is single, large, three-cornered, acute, and surrounded with membranaceous borders. The leaves are placed on long footstalks, which rise immediately from the root; they are heart-shaped, smooth, ribbed on their under side, and waved on their edges; the stalk rises to the height of four feet; it is of a pale green, furnished with a small leaf at each joint, and the uppermost divided into branches supporting numerous panicles of flowers, which appear in June.

This plant is supposed to be the true Tartarian rhubarb, the root of which (so well known in medicine) is thick, of an oblong figure, large at the head, and tapering pretty suddenly as it extends in length; it is sometimes single, but more usually divided into two or three parts at the lower end. It is brought to us in unequal pieces, from four to five or six inches in length, and three or four thick; it is a little heavy, and of a dusky yellow without side, but within is marbled or variegated with yellow and red in the manner of a nutmeg; it is of a somewhat lax and spongy texture, of a sub-acid bitterish and somewhat astringent taste, with an agreeable aromatic smell.

Rhubarb is to be chosen fresh, tolerably hard, and moderately heavy, and such as does not dust the fingers in handling; such as, infused a few minutes in water, gives it a fine yellow, and when bruised in a mortar has a reddish colour with the yellow. Rhubarb is not so often adulterated as damaged; care is to be taken that it be not wet or rotten: much of it is subject, after sleeping too long, to be worm-eaten and full of holes on the surface.

It has been learnedly controverted by botanists, whether the antients were acquainted with the true rhubarb; their sort appears to be the rapontic, or English rhubarb, which is another species of rheum, the roots of which are greatly inferior to those of the true kind. It is brought to us from Russia and from the East-Indies; it grows in great plenty on the confines of China and Tartary, and in many parts of Tartary itself; the mountains of Tibet abound with it, and a very considerable part of what is sent into Europe, grows there.

It was long before the true rhubarb-plant was known in Europe; but of late years it has been introduced among us, and as it will thrive in this climate very well, we may reasonably entertain the agreeable

agreeable expectations, that a sufficient quantity of this valuable drug will be raised in a few years, so as at least to supply our own consumption.

The propagation of these plants is by seeds, which should be sown in autumn, soon after they are ripe, in the place where they are intended to remain, as the plants should not be removed. In the spring they will make their appearance, when they should be howed out, as practised with carrots, leaving them at the last hoeing out at the distance of about a foot and a half asunder, after which they require no other care than to keep them clear from weeds; in autumn the leaves of these plants decay, then the ground should be made clean; and in the spring, before the plants begin to put forth new leaves, the ground should be hoed and made clean again.

The second year after the plants come up, many of the strongest will produce flowers and seeds; but the third year most of them will flower: the seeds, when ripe, should be gathered, and not suffered to scatter, lest they should grow to injure the old plants. The roots of these plants will remain many years without decaying; and, it is said, the old roots of rhubarb are much preferable to the young ones.

They delight in a rich soil, not too dry, nor over moist, and where there is a good depth for their roots to run down; in such land, their leaves will be very large, and their roots will grow to a great size.

Rhubarb greatly strengthens the stomach and bowels, and is an excellent medicine against choler, and other distempered contents of the intestinal and mesenteriac glands: it is given, with great success, in all obstructions of the liver, in the jaundice, diarrhoea, fluor albus, and gonorrhoea; and the kidneys do not lie too remote from its influences, for it frequently passes so much that way, as to discover itself in the colour of the urine; it, therefore, is very good in obstructions of the reins and uterus; but in the jaundice, it almost passes for infallible: it is good against worms in children, and is the best purge that can be given them to clear away those crudities in the bowels, which are apt to breed them: it also gives a firmness to the fibres, which, from the slipperiness of children's diet, are generally too lax, so that its repetition to them can hardly be too frequent.

Rhubarb is given in powder, in infusion, and in its own crude solid state, the chewing it being, perhaps, the best way of giving it of all others. When it is intended to strengthen the stomach and assist digestion, the quantity of twenty-five grains, or thereabout, should be chewed daily on these occasions, an hour before eating: this is also the best way of taking it against obstructions of the viscera.

Its dose, in powder, is from half a scruple to two scruples; in infusion, about a dram of it will purge gently, but the dose may be increased to two drams:

it is observable, that neither the infusion nor the decoction, nor even the extract, of rhubarb, purge near so briskly as the root itself in powder.

*Monks-RHUBARB, Lapathum.* See the article LAPATHUM.

RHUMB, RUMB, or RUM, in navigation, a vertical circle of any given place, or the intersection of such a circle with the horizon; in which last sense rhumb is the same with a point of the compass. See the article COMPASS.

RHUS, *Sumach*, in botany, a genus of plants, whose flower consists of five ovate erect patent petals, with five very short filaments, topped with small antheræ shorter than the corolla; the pistillum hath scarce any style, and crowned with three small heart-shaped stigmata; the fruit is a roundish hairy berry, containing a single osseous seed: this genus comprehends several species, among which are included by Linnæus the cotinus and toxicodendrous of Tournefort. The leaves and seeds of the elm-leaved sumach are used in medicine, and are accounted astringent and styptic, and good for all kinds of fluxes and hæmorrhages. This species grows naturally in the southern parts of Europe, as also in Turkey, where the branches are used for tanning leather.

RHYME, RHIME, RYME, or RIME, in poetry, the similar sound, or cadence and termination of two words which end two verses, &c. Or rhyme is a similitude of sound between the last syllable or syllables of a verse, succeeding either immediately or at a distance of two or three lines.

Rhymes are either single, double, or triple, though the two last are much disused. Single rhymes are divided into perfect or whole rhimes, and imperfect or half rhymes. A whole or perfect rhyme is where there is a similitude of sound without any difference: an imperfect rhyme is where there is a similitude of sound, with a difference either in respect of the pronunciation or orthography, but chiefly the former. Single rhymes are again divided into feminine and masculine rhymes: the feminine rhyme is that where the last syllable of the rhyme ends with an *e* mute: and the masculine rhymes are those of all other words. Double rhymes are those where two words terminate alike through the whole two last syllables. Plain rhymes are those where the two rhyming verses succeed immediately to each other: and cross rhymes are those where the verses are so disposed as that the first rhymes with the third, and the second with the fourth.

There is no rule in poetry, says Du Bos, whose observance costs so much trouble, and is productive of less beauties in verse, than that of rhyming. Rhyme frequently maims and almost always enervates the sense of the discourse, for one bright thought which the passion of rhyming throws in our way by chance, is, without doubt, every day the cause

cause of a hundred others that people would blush to make use of, were it not for the richness or novelty of the rhyme with which these thoughts are attended.

And yet the allurements of rhyme has nothing in it worth comparing to the charms of numbers and harmony. The terminating of a syllable with a particular sound is no beauty in itself. The beauty of a rhyme is only a relative one, which consists in a conformity of termination between the two last of two corresponding verses. This ornament therefore, which is of so short a duration, is perceived only at the end of two verses, and after having heard the last word of the second verse, which rhymes to the first. One is not even sensible of this pleasure, but at the end of three or four verses, if the masculine and feminine rhymes are interwoven, so that the first and fourth be masculines, and the second and third feminines: a mixture which is very much used in several kinds of poetry. But even in those verses where the richness thereof discovers itself at the end of the second verse, it is the greater or lesser conformity between the two last words of these verses, which forms its elegance. Nor, for the most part, do people upon hearing the second rhyme, recal the first distinctly enough, to be charmed with their perfection. Their merit is known rather by reflection than sensation, so trifling is the pleasure by which it tickles the ear. Numbers and harmony are a light which throws out a constant lustre; but rhyme is a mere flash, that disappears after having given only a short-lived splendor.

**RHYTHM**, *ῥυθμος*, in music, the variety in the movement, as to the quickness or slowness, length or shortness of the notes. Or, it may be defined more generally, the proportion which the parts of the motion have to each other.

**RIBES**, the currant-bush, in botany. See the article **CURRENT**.

**RIBS**, *Costæ*, in anatomy, certain long arched bones, serving to form or sustain the inner sides of the thorax. See the article **THORAX**.

The ribs are twenty-four in number, twelve on each side; their figure is an imperfect segment of a circle: their size is very different, the middle ones being largest, and the upper and lower much smaller: they are harder, rounder, and more incurved towards their articulations with the vertebræ, than at the other extremity towards the sternum, which is thinner, broader, and more spongy. The ribs are distinguished into true and spurious; the true ribs are the seven upper pair, which are thus distinguished, as forming the most perfect arches, and as having a strong articulation with the sternum. The five lower are called nothæ, or spurious ribs, as being smaller, shorter, and more cartilaginous than the rest, and not reaching so far as the sternum, which make their articulations very lax, in regard

they terminate in long soft cartilages, which bending upwards, are joined to the upper ribs. The several ribs have been distinguished by many authors, each under its peculiar name; but this is not necessary, as they are as easily known by the names first, second, &c. On the inside of the true ribs, except the lowest, and sometimes the next to it, runs a pretty deep sinus, reaching from the end next the spine, almost to its juncture with the cartilage. In the anterior extremities the cartilages of the seven true ribs are all joined to the sternum; the eighth, ninth, and sometimes the tenth, cohere either with the sternum, or mutually adhere to one another, by means of their transverse cartilages. The anterior extremities of all the others are loose and free, between the muscles of the abdomen and the diaphragm. In the posterior extremities there are in most of them two capitula, or heads, which are firmly joined to the vertebræ of the back, yet so as to form moveable articulations; for the use of which, see the article **RESPIRATION**.

The ribs are liable both to fractures and luxations. In a slight fracture, the separated bones are to be put into their places, a compress dipped in spirit of wine is to be laid on, and then covered with splints and a circular bandage. If any sharp pieces of the ribs should pierce the pleura, &c. it will be proper to open the skin, and extract the fragment. The ribs are but seldom dislocated; but when this happens, they are to be replaced as soon as possible. See **FRACTURE** and **LUXATION**.

**RIBWORT**, in botany. See the article **PLANTAIN**.

**RICCIA**, in botany, a genus of cryptogamous plants, of the flag kind, consisting of a foliaceous matter, procumbent on the ground, on which there are evident male and female fructifications, sometimes both on the same, and sometimes on different plants of the same species; the male flower has neither calyx nor corolla, but consists of a single vesicle awl-shaped truncated anthera, opening at the top and growing to the leaves; the female flower has no corolla and scarce any calyx, consisting principally of a globose unilocular pericarpium, in which is contained a great number of seeds.

**RICE**, *Oryza*, in botany. See the article **ORYZA**.

**RICHARDIA**, in botany, a genus of plants, whose flower is monopetalous and of a cylindraceous funnel form, with the limb divided into six erect acute segments, with the same number of stamina; there is no pericarpium, the seeds are three in number, round on one side, and angulated on the other, broader at the top, and gibbous.

**RICINUS**, in botany, a genus, producing male and female flowers on the same plant, which are both destitute of a corolla; the cup of the male is divided into three oval and concave segments; the filaments

filaments are a very numerous slender joining in several bodies, and topped with roundish twin antheræ: the female flower-cup is divided into five ovate concave deciduous segments, containing three pistils, and the fruit is a roundish three furrowed capsule, consisting of three valves, and containing the cells, each including one almost oval seed.

Most of the species belonging to this genus are natives of the West-Indies. From the seeds of these plants the inhabitants extract an oil for the use of lamps; the seeds have been given formerly to purge watery humours; but are rather too violent to be used with safety, and are therefore now much in disuse.

**RICKETS**, *Rachitis*, in medicine, a disorder incident to children, proceeding from an unequal nutrition.

Children are seldom attacked with rickets before they are nine months old, and after they are two years old. It may originally proceed from the disorders of the parents, and may be increased by those of the nurse. It is also promoted by feeding the child with aqueous and mucous substances, crude summer-fruits, fish, and too great a quantity of sweet things; by sitting too much, especially in a perforated chair, with its coats up; by a striking in of the itch, &c.

This disorder is known from a flaccid tumour of the head and face, a flabby loose skin, a swelling of the belly, and a falling away of the rest of the other parts, especially of the muscles; from protuberances of the apophyses of the joints, such as the wrists, ankles, and knees, from the largeness of the jugular veins and arteries, while the rest decrease; from knotty ribs, a narrow breast, and carious teeth, &c.

The cure, according to Boerhaave, is to be attempted with light, nourishing, dry aliment; not fat, but seasoned, and taken often; with little sound drink, such as mild beer, or ale; with a dry warm air, and warm woollen clothing; with being carried about in the arms, or drawn in a vehicle over the stones, and often shook, swung, and put in motion; with repeated frictions, especially of the belly and spine of the back with warm dry flannel, sprinkled with aromatics; with gentle emetics, frequently though prudently repeated; with strengthening purges for several days successively; and with cold bathing, the child being put to sweat between blankets every day, as soon as he comes out of the water.

Particularly for food, the bread should be biscuit, with a little saffron and spices; the flesh should be pigeons, pullets, veal, rabbits, mutton gently roasted, minced and mixed with biscuit, salt, a little parsley, thyme, nutmeg, or the like. He may also eat rice, millet, or pearl barley, boiled with raisins, to which add a little wine and spice.

The drink may be red wine, of which an ounce may be given three or four times a day; as also Brunswic mum and English beer, which, in the summer, may be mixed with spaw-water. Let the pillow and bed be filled with the following leaves dried in the shade, viz. of male fern, three pounds; of marjoram, baum, and mint, each two handfuls; and of the flowers of melilot, sweet-trefoil, elder, and roses, dried in the shade, of each two ounces: reduce them all to powder, and mix them with double the quantity of barley-chaff.

**RIDE**, in the sea-language, is a term variously applied: thus a ship is said to ride, when her anchors hold her fast, so that she does not drive, by the force either of the wind or tide. A ship is said to ride across, when she rides with her fore and main yards hoisted up to the hounds, and both yards and arms topped alike. She is said to ride well, when she is built so as not to over-beat herself in a head-sea, the waves over raking her from stem to stern. To ride athwart, is to ride with her side to the tide. To ride betwixt wind and tide, is to ride so as the wind has equal force over her one way, and the tide the contrary way. If the wind has more power over the ship than the tide, she is said to ride wind-ward, or to ride a great wind. And she is said to ride a-portoise, when the yards of a ship are struck down upon the deck.

**RIDE**, of hazel, or other wood, is a cluster of sprigs shooting out from the same root.

**RIDEAU**, in fortification, is a small elevation of earth, extending lengthwise on a plane, and serving to cover a camp, or to give an advantage to a post. Rideaus are also convenient for those who would besiege a place, and serve to secure the workmen in their approaches to the foot of a fortress.

Rideau is also used sometimes for a trench, the earth of which is thrown upon its sides, to serve as a parapet for covering the men.

**RIDER**, a term used for an after-clause added to a bill while depending in parliament.

**RIDERS**, in a ship, are large timbers, both in the hold and aloft, bolted on to other timbers to strengthen them, when the ship is discovered to be too slightly built.

**RIDGE**, in agriculture, a long piece of rising land, between two furrows.

Mr. Tull observes, that the method of ploughing lands up into ridges is a particular kind of tillage, the chief use of which is the alteration it makes in the degrees of heat and moisture. But the principal advantage this gentleman proposes from ridges is the draining wet hills, where the upper stratum is mould, and the second stratum clay. These ridges he observes should be plowed across the hill, almost horizontally, that their parting furrows lying open, may each serve as a drain to the ridge next below it; for when the plough has made

the

the bottom of these horizontal furrows a few inches deeper than the surface of the clay, the water will run to their ends very securely, without rising into the mould, provided no part of the furrows be lower than their ends. These ridges and their parting furrows must be made more or less oblique, according to the form and declivity of the hill; but the more horizontal they are, the sooner the rain-water will run off the lands: for in that case, it will run to the furrows, and reach them at right angles. Every one of these horizontal trenches receives all the water from the rills, or little gutters, which in these quagmire-hills run betwixt the mould and the clay; these are all cut off by the trenches, which receive the water at their upper sides, and carry it away, as the gutters of lead, placed under the eaves of a house, carry away the rain-water. These ridges should be plowed in pairs, without throwing any earth into the trenches; and at every time of ploughing, the pairs must be changed, so that the furrow which had two ridges turned towards it one time, must have two turned from it the next.

**RIDGE**, in building, the highest part of the roof or covering of a house.

**RIDGES of a horse's mouth**, are wrinkles or risings of flesh in the roof of the mouth, running a-cross from one side of the jaw to the other with furrows between them. On the third or fourth of these ridges the farriers strike with a horn, in order to bleed a horse, whose mouth has been over-heated.

**RIDGLING**, or **RIDGEL**, among farriers, &c. the male of any beast that has been but half gelt.

**RIDICULE**, in matters of literature, is that species of writing, which excites contempt with laughter.

**RIGADOON**, a gay and brisk dance, borrowed originally from Provence in France, and performed in figure, by a man and a woman.

**RIGGING of a Ship**, is all her cordage and ropes, belonging to her masts, yards, &c. See **SHIP**, **ROPE**, **CORDAGE**, &c.

**RIGHT**, in geometry, signifies the same with straight: thus, a straight line is called a right one. See **LINE**.

As for right angle, right ascension, right cone, right descension, right sine, right sphere, &c. they are explained under the articles **ANGLE**, **ASCENSION**, &c.

**RIGHT**, *Jus*, in law, not only denotes property, for which a writ of right lies, but also any title or claim, either by virtue of a condition, mortgage, &c. for which no action is given by law, but an entry only.

**RIGIDITY**, in physics, denotes a brittle hardness. See the article **HARDNESS**.

It is opposed to ductility, malleability, and softness. See **DUCTILITY**, &c.

**RIGLET**, or **REGLET**. See **REGLET**.

**RIGOR**, in medicine, a convulsive shuddering, from severe cold, an ague-fit, or other disorder.

**RIM**, in a watch, or clock, the edge or border of the circumference or circular part of a wheel.

**RIND**, the skin of any fruit that may be cut off or pared.

The outer coat of the chestnut, set with prickles, is particularly termed the urchin-like rind.

Rind is also used for the inner bark of trees or that whitish soft substance which adheres immediately to the wood.

In the modern theory of vegetation, the sap is supposed to pass through the rind, in its return from the extremities of the branches to the root. Others suppose its vessels to do the office of arteries, whence Mr. Bradley calls them arterial vessels.

**RING**, an ornament of gold, silver, &c. made of a circular form, and generally worn on the finger.

**RING-BONE**, in farriery, a hard callous substance, growing in the pastern of a horse, above the coronet: it is thus called from its growing quite round like a ring.

**RING-DIAL**. See the article **DIAL**.

**RING-WORM**, in medicine, the same with the serpigo. See the article **SERPIGO**.

**Fairy RING**, or **CIRCLE**. See **FAIRY**.

**Saturn's-RING**, in astronomy. See the article **SATURN**.

**RIOT**, in law, is where three or more persons, assembled together commit some unlawful act, with force and violence, to the disturbance of the peace; as beating some person, forcibly entering upon the possession of the lands, houses, &c. of another, or breaking down inclosures, houses, &c.

**RIPENERS**, in surgery, medicines that promote suppuration, otherwise called suppuratives. See **SUPPURATIVES**.

**RISING**, *Ortus*, in astronomy, the appearance of the sun, a star, &c. above the horizon of any place.

There are three kinds of poetical rising of the stars, viz. acronycal, cosmical, and heliacal. See **ACRONYCAL**, &c.

The heavenly bodies always appear above the horizon before they really arrive at it, on account of refraction. See the article **REFRACTION**.

**RITE**, *Ritus*, among divines, denotes the particular manner of celebrating divine service, in this or that country. See the article **RITUAL**.

**RITORNELLO**, or **REPEAT**, in music, the burden of a song, or the repetition of the first or other verses of a song at the end of each stanza or couplet.

**RITUAL**, a book directing the order and manner to be observed in celebrating religious ceremonies;

nies, and performing divine service in a particular church, diocese, order, or the like.

**RIVER**, *Fluvius*, or *Flumen*, a current or stream of fresh water flowing in a bed or channel, from its source into the sea. See the article **SPRING**.

**RIVULET**, a diminutive of river. See the article **RIVER**.

**RIVINIA**, in botany, a genus of plants whose flower is apetalous; the cup is persistent and coloured, and divided into four oval concave segments; the fruit is a globose berry placed in the cup, and contains a roundish hard seed.

**ROACH**, in ichthyology, a species of cyprius, with the iris and belly fins usually red: it is generally, when full grown, nine inches long, but it sometimes grows considerably larger. See the article **CYPRINUS**.

**ROACHING** of *alum*, is the last process in making alum, which, being sufficiently washed in a cistern of strong alum water, is put into large pans, and a quantity of water added to it; and then being set over the fire to melt, and boil a little, it is scooped into a great cask, where it is suffered to stand and crystallize, and is what they call roach, roached, or rock alum.

**ROAD**, an open way, or public passage, forming a communication between one place and another.

**ROAD**, in navigation, is a place of anchorage at some distance from shore, where vessels usually moor to wait for a wind or tide proper to carry them into harbour, or to set sail.

When the bottom is firm, clear of rocks, and sheltered from the wind, it is called a good road; and when there is but little land on any side, it is termed an open road.

**ROAN-TREE**, *Sorbus*, in botany. See the article **SORBUS**.

**ROASTING**, in metallurgy, the separation of volatile bodies from those which are more fixed, by the combined action of air, and fire; and is generally the first process in the separation of metals from their ores: it differs from sublimation only in this, that in this operation the volatile parts are dissipated when resolved into vapours; whereas in that, they are preserved. See **SUBLIMATION**.

**ROB**, in pharmacy, the juices of fruits purified and inspissated till it is of the consistence of honey.

**ROBBERY**, in law, a felonious taking away another man's goods, from his person, presence, or estate, by putting him in fear.

**ROBERVALLIAN LINES**, certain lines used for the transmutation of figures, and so called from their inventor M. de Roberval.

**ROBINIA**, in botany, a genus of plants, producing papilionaceous flowers; the vexillum is roundish, large, patent and obtuse; the wings are oblong ovate, with short obtuse appendices, and the carina is almost half round, compressed, blunt, and the

length of the wings; the fruit is a large compressed, long, gibbous pod, containing a few kidney shaped seeds.

The flowers of some of the species, make a beautiful appearance, but being natives of the West-Indies, the plants require a hot-house for their preservation in this climate.

**ROCAMBOLE**, in botany, a species of garlic. See the article **GARLIC**.

**ROCK-ROSE**, *Cistus*, in botany. See the article **CISTUS**.

**ROCKET**, in pyrotechny, an artificial fire-work, consisting of a cylindrical case of paper, filled with a composition of certain combustible ingredients; which being tied to a stick, mounts into the air, to a considerable height, and there bursts.

**ROCKET**, in botany, the English name for a beautiful species of hesperis, it is a biennial plant, and increased by cuttings in the summer; they require a strong land, and flower in June; those with double flowers are most regarded.

**Water-ROCKET**, in botany. See **SESYMBRIUM**.

**ROD**, a wand, or long slender staff.

**ROD** is also used for a land measure of sixteen feet and a half: the same with perch and pole.

**ROD**, in gauging. See **GAUGING**.

**Black-ROD**, a staff carried by the king's gentleman usher, as a badge of his office; this rod or staff is black, and has a lion in gold on its top.

**ROE**, the spawn or seed of fish. That of the male-fishes is usually distinguished by the name of soft-roe, or milt, and that of the female, by hard-roe, or spawn.

**ROE** is also one of the beasts of chase, of the deer kind. See **CERVUS**.

The roe buck is called, the first year, a hind; the second, a gyrl; the third, an henus; the fourth, a roe-buck of the first head; and the fifth, a fair roe-buck.

**ROELLA**, in botany, a genus of plants, whose flower is monopetalous and funnel shaped, divided at the limb into five erecto-patent segments, with five scaly nectariums, which are connivent and placed in the bottom of the corolla; the stamina are five subulated filaments, sitting in the nectarium, and terminated with connivent awl-shaped antheræ: the fruit is a cylindraceous capsule, shorter than the cup, having two cells, which contain numerous angulated seeds. This genus has some affinity to the campanula.

**ROGATION**, in the Roman jurisprudence, a demand made by the consuls, or tribunes of the Roman people, when a law was proposed to be passed. Rogatio is also used for the decree itself made in consequence of the peoples giving their assent to this demand, to distinguish it from a senatus consultum, or decree of the senate.

topped with three-cornered antheræ. The fruit is formed of the fleshy base of the cup, and is of a turbinated form, coloured, soft, containing one cell, drawn together at the neck, and coronated with some irregular lacinix, and includes many oblong hairy seeds fastened on each side of the cup.

The varieties of double roses are numerous; and we may venture to say, that there is no shrub yet known that equals the rose, if the fragrant and beauty of the flowers are considered together. The most beautiful and rare is a species lately introduced into England from Pennsylvania, by that very curious gardener and nursery-man Mr. Bandel of Greenwich, who has them in the greatest perfection. All the sorts of roses are propagated either by suckers or layers; the best season for laying is in October, which is also the proper time for planting, though in moist land the spring is as well.

The flowers of the red rose are reckoned astringent, cleansing, and proper to strengthen the stomach, to stop hæmorrhages, vomiting, and fluxes; those of the damask-rose are purgative; and the fruit of the wild-rose or briar is pectoral. The rose-water of the shops, distilled from the flowers of the damask-rose, has been celebrated for many virtues; but its fragrant smell is the only quality regarded in it. There is also a syrup made either from the juice or infusion of the fresh flowers of the damask-rose.

*China-Rose.* See HIBISCUS.

*Gilder-Rose.* See VIBURNUM.

*Rock-Rose.* See CISTUS.

*Rose of Jericho, Anastatica*, in botany, a plant which grows naturally in Syria; it is low and annual, dividing into many irregular woody branches near the root; at each joint is placed a single, oblong, hoary leaf; and at the same places come out small single flowers of a whitish-green colour, each composed of four petals disposed in the form of a cross; these are succeeded by short wrinkled pods, having four small horns, opening into two cells, each containing a single brown seed. This plant has the singular property, that after being kept dry for several years, if it is put into water it will dilate and expand itself, so as to open and disclose the seed-vessels and seeds in a very extraordinary manner; and is therefore kept by the curious in their repositories. It is propagated by seeds, which should be sown in the beginning of April, on a border of light sandy earth, where it is intended to remain.

*ROSE-ROOT, Rhodiola.* See the article RHODIOLA.

*ROSE*, in architecture, an ornament cut in the form of a rose, chiefly used in corniches, frizes, vaults of churches, &c. and particularly in the middle of each face in the Corinthian abacus.

*ROSE-NOBLE*, an English gold coin, first struck in the reign of Edward III. It was formerly cur-

rent at 6s. 8d. and so called because stamped with a rose.

*ROSEMARY, Rosmarinus*, in botany, a genus of plants, whose flower is monopetalous and ringent, the upper-lip of which is short, erect, and bifid, with the margin reflexed; the under-lip is reflexed and trifid, the middle segment being large, concave, and narrow at the base; the stamina are two subulated filaments, inclining to the upper-lip, and topped with single antheræ; there is no pericarpium, the bottom of the cup containing four ovate seeds.

Rosemary grows wild in many parts of Spain, France, and Italy, and is cultivated in our gardens; it is propagated by cuttings or slips taken off in the spring of the year and planted in a bed of light fresh earth, and in the following autumn they may be transplanted where they are intended to remain.

In medicine, the flowers and leaves of the narrow-leaved rosemary are made use of both for internal and external purposes; they are full of volatile parts, as appears by their taste, smell, and analysis. They strengthen the brain and sight, and sweeten the breath, are good against the palsy and epilepsy, as well as obstructions of the viscera; they restore the tone of the solids, and incise and attenuate gross humours: the conserve of the flower is cordial, stomachic, and cephalic; and from the flowers and young leaves the celebrated Hungary water is made, by being digested in spirits of wine; and the spirit distilled off a small quantity of which, diluted with common water, is reckoned excellent in dislodging and bringing away wax from the ears. Boerhaave looks upon the essential oil to be the best remedy against the epilepsy, and a few drops of it are to be given in wine; the usual dose is five or six drops.

*ROSICRUCIANS, or ROSYCRUCIANS.* See ROSYCRUCIANS.

*ROS-SOLIS*, sun-dew, an agreeable spirituous liquor, composed of burnt brandy, sugar, cinnamon, and milk-water; and sometimes perfumed with a little musk: it is so called, as being at first prepared wholly of the juice of the plant *ros-solis*, or *drosera*.

*ROSTRA*, in antiquity, a part of the Roman forum, whereon orations, pleadings, funeral harangues, &c. were delivered.

*ROSTRUM* literally denotes the beak or bill of a bird; and hence it has been figuratively applied to the beak, or head of a ship.

*ROSTRUM*, in chemistry, implies the nose or beak of a common alembic, which conveys the liquor distilled into its receiver. See the article ALEMBIC.

*ROSYCRUCIANS, ROSICRUCIANS, or Brothers of the Rosy Cross*, a name assumed by a sect or cabal of hermetical philosophers, who appeared, or at least were first taken notice of, in Germany, in the beginning of the sixteenth century. They pretended

tended to be masters of all sciences, and to have many important secrets, particularly that of the philosopher's stone. See the article PHILOSOPHER.

Their society is frequently denoted by the abbreviatures F. R. C.

ROT, a disease incident to sheep, arising from wet seasons, and too moist pasture.

It is a very hard thing to prevent the rot, if the year proves very wet, especially in May and June. Salt marshes, and lands where broom grows, are the best places of preservation for them. Sheep are sometimes all cleared of the rot, when not too far gone with it, only by removing them into broom-fields. Scurvy-grass, mustard, parsley, and thyme are also good for the prevention of it.

Some propose the giving sheep half a handful of bay-salt every month, or oftener; and there is great probability that this may be of service; but the rational way of attacking all disorders in cattle, is by considering what are the causes of them. It will appear, upon enquiry, that wet seasons are the general occasions of the rot in sheep, and therefore it would be advisable for the owners, when such seasons come on, to remove those animals into the driest pastures they can, and then to feed them principally with dry sweet hay, oats, bran, and the like; this would prevent the occasion: and if they were already a little infected, some salt given with their dry food, would be a happy means of curing them.

ROTA, wheel, in mechanics. See the article WHEEL.

There is a celebrated problem in mechanics, called *rota Aristotelica*, Aristotle's wheel, because that philosopher was the first who took notice of it. The matter to be accounted for, is how a point in the nave of a wheel comes to describe, during one revolution, a line equal to the length of the outer circumference of the wheel, when a point in the outer circumference does no more.

Many great men having attempted in vain to account for this phenomenon, Mr. de Meyran, a French gentleman, had the good fortune to light on a solution of it, which the Academy of Sciences declared to be satisfactory. It is this: a wheel is only acted on, or drawn forward, in a right line: its circular motion, or rotation, arising purely from the resistance of the ground whereon it is applied. Now this resistance is equal to the force wherewith the wheel is drawn in the right line, inasmuch as it defeats that direction, and, consequently, the causes of the two motions being equal, their effects are equal too; or, a point in the wheel describes, during one revolution, a right line on the ground equal to its outer circumference.

But as to the nave of the wheel, the case is otherwise; for though it is drawn in a right line by the same force as the outer circumference, yet it only

turns round because the wheel turns, and can only turn with it, and in the same time. Hence it follows, that its circular velocity is less than that of the circumference of the wheel, in the ratio of the two circumferences; and therefore of course, its circular motion is less than its rectilinear one. Since then it necessarily describes a right line equal to that described by the circumference of the wheel, it can only do it by sliding along.

ROTA is also the name of an ecclesiastical court at Rome, composed of twelve prelates, whereof one must be a German, another a Frenchman, and two Spaniards; the other eight are Italians, three of whom must be Romans, and the other five, a Bolognaese a Ferraran, a Milanese, a Venetian, and a Tuscan.

This is one of the most august tribunals in Rome, which takes cognizances of all suits in the territory of the church, by appeal; as also of all matters beneficiary and patrimonial.

ROTATED FLOWERS, among botanists, are such flowers which spread open so as to form the shape of a wheel.

ROTATION, in geometry, a term chiefly applied to the circumvolution of any surface round a fixed and immoveable line, which is called the axis of its rotation: and by such rotations it is, that solids are conceived to be generated. See the article GENESIS.

The late ingenious Mr. de Moivre shews how solids, thus generated, may be measured or cubed. His method is this: for the fluxion of such solids, take the product of the fluxion of the absciss, multiplied by the circular base; and suppose the ratio of a square to the circle inscribed in it to be  $\frac{n}{1}$ : then

the equation, expressing the nature of any circle, whose diameter is  $d$ , is  $yy = dx - xx$ . There-

fore  $\frac{4dx - x^2}{n}$  is the fluxion of a portion of the

the sphere; and, consequently, the portion itself  $4\frac{1}{2}dx - x\frac{1}{3}x^3$ , and the circumscribed cylinder

is  $\frac{4dx - x^3}{n}$ ; and, therefore, the portion of the

sphere is to the portion of the circumscribed cylinder, as  $\frac{1}{2}d - \frac{1}{3}x$  to  $d - n$ .

ROTATION, or REVOLUTION, in astronomy. See REVOLUTION.

ROTONDO, or ROTUNDO, in architecture, an appellation given to any building that is round both within and without side, whether it be a church, a salon, or the like.

The most celebrated rotondo of the ancients, is the pantheon at Rome. See PANTHEON.

ROTTENNESS, putrefaction. See the article PUTREFACTION.

ROUND, *Rotundus*, in geometry. See the articles CIRCLE, GLOBE, and SPHERE.

ROUND, in a military sense, signifies a walk which

which some officer, attended with a party of soldiers, takes in a fortified place around the ramparts, in the night-time, in order to see that the centries are watchful, and every thing in good order.

**ROUNDELAY**, a kind of ancient poem, thus termed, according to Menage, from its form, because it turns back again to the first verse, and thus goes round.

This poem is little known among us, but is very common among the French, who call it *rondeau*. It consists commonly of thirteen verses, eight whereof are in one rhyme, and five in another. It is divided into couplets, at the end of the second and third whereof the beginning of the roundelay is repeated, and that, if possible, in an equivocal sense.

**ROUNDELET**. See **RUNDLET**.

**ROUT**, a public road, highway, or course, especially that which military forces take.

This word is also used for the defeat and flight of an army.

**ROUT**, in law, is applied to an assembly of persons, going forcibly to commit some unlawful act, whether they execute it or not.

The difference between a rout and a riot seems to be this, that a rout is where persons are unlawfully assembled, and have moved forwards, in order to commit the unlawful act intended, but part without doing it; whereas, riot is taken for the disorderly fact, committed by any such unlawful assembly. See **RIOT**.

**ROWEL**, among farriers, a kind of issue, made by drawing a skain of silk, thread, hair, or the like, through the nape of the neck, or other part, of a horse; answering to what, in surgery, is called a seton. See the article **SETON**.

The rowelling of horses is a method of cure frequently had recourse to, in cases of inward strains, especially about the shoulders or hips, as also for hard swellings not easy to be dissolved.

The operation is this: a little slit being made through the skin, about a handbreadth below the part aggrieved, big enough to put a swan's quill in, the skin is raised from the flesh, the end of the quill put in, and the skin blown from the flesh upwards, and all over the shoulder; then, the hole being stopped with the finger, the part blown is beat with a hazle-stick, and the wind spread with the hand all over, and then let go; this done, a skain of horse-hair, or red farsenet, half the thickness of the little finger, is put in a rowelling-needle, seven or eight inches long, and the needle is put into the hole, and drawn through again, six or seven inches higher; then the needle is drawn out, and the two ends of the rowel tied together, anointing it every day, as well as before the putting it in, with sweet butter and hog's grease, and drawing it backwards and forwards in the skin, to make the putrid matter discharge itself more plentifully.

Others, disliking these rowels, as making too large a sore and scar, use the French rowel, which is a round piece of stiff leather, with a hole in the midst, laying it flat between the flesh and skin, the hole in the rowel just against that in the skin, sewing it with a needle and thread drawn through the hole and the skin, cleaning it once in two or three days, and then anointing it afresh.

**ROWELS of a Spur**. See **SPUR**.

**ROWS of Trees**. See **PARALLELISM**.

**ROYENA**, in botany, a genus of plants whose flower is monopetalous, the tube is the length of the cup, and the limb is spreading, reflexed, and divided into five ovate segments; the stamina are ten very short filaments, topped with oblong, acute, and twin antheræ. The fruit is an ovate, four-furrowed, and unilocular capsule, containing four oblong triangular nuts.

**RUBIA**, madder, in botany. See the article **MADDER**.

**RUBICAN**, in the manege. A horse is said to be of a rubican colour, when of a bay, sorrel, or black, with a light grey or white upon the flanks, but so that this grey or white is not predominant there.

**RUBIFYING**, in chemistry, the act of turning a thing red by the force of fire, &c.

**RUBIGALIA**, in antiquity, a feast celebrated by the Romans, in honour of the god Rubigus, or the goddess Rubigo, to engage those deities to preserve the corn from blights and mildews.

The rubigalia were instituted by Numa, in the eleventh year of his reign, and were celebrated on the seventh of the calends of May.

**RUBIGO**, a disease incident to corn, commonly called mildew, being a species of blight. See the article **BLIGHT**.

**RUBRIC**, *Rubrica*, in the canon-law, signifies a title or article in certain ancient law-books; thus called, because written, as the titles of the chapters in our ancient bibles are, in red letters.

Rubrics also denote the rules and directions given at the beginning, and in the course of, the liturgy, for the order and manner in which the several parts of the office are to be performed. There are general rubrics and special rubrics, a rubric for the communion, &c. In the Romish Missal and Breviary are rubrics for matins, for lauds, for translations, beatifications, commemorations, &c.

**RUBUS**, the **BRAMBLE**, in botany, a genus of plants, whose flower-cup is cut into five oblong patent segments, in which is inserted five roundish erecto-patent petals of the same length; the filaments are numerous, inserted in the calyx, and topped with roundish compressed antheræ; the fruit is a compound berry, formed of many roundish acini, arranged into a cluster, convex at the top, and concave below, each acinus is unilocular, and contains

tains a single oblong seed; the acini of most of the species coalesce together, so as not to be separated without breaking.

The common bramble or blackberry bush, grows wild in woods, hedges, &c. in most parts of England, the root of which is slender, creeping, and knotty, from which arise several long, weak, bending, greenish-red, angular, pithy branches, armed with strong crooked prickles; the leaves are oblong, pointed, dentated on the edges, rough, brown on the upper parts, but whitish below, placed by threes or fives on the same pedicle; the flowers come out on the extremities of the branches, in June, July, or August; and the fruit is ripe in autumn.

The root of this plant is cleansing, astrigent, and absorbent; the leaves pounded and applied to ring-worms and ulcers of the legs, heal them in a short time, and the fruit when ripe is cooling and quenches thirst.

To this genus belong the raspberry. See the article RASPBERRY.

**RUBY**, *Rubinus*, in natural history, a species of the *chroastasma* class of gems, being a beautiful gem of a red colour with an admixture of purple. See GEM.

This, in its most perfect and best coloured state, is a gem of prodigious beauty and extreme value; it is often found perfectly pure and free from blemishes or foulness, but much more frequently debased greatly in its value by them, especially in the larger specimens. It is of very great hardness, equal to that of the sapphire, and second only to the diamond. It is various in size, but less subject to variations in its shape than most of the other gems. It is usually found very small, its most common size being equal to that of the head of the largest sort of pins; but it is found of four, eight, or ten carats; and sometimes, though very rare, up to twenty, thirty, or forty. It is never found of an angular or crystalliform shape, but always of a pebble-like figure, often roundish, sometimes oblong and much larger at one end than the other, and in some sort resembling a pear, and is usually flatted on one side. It commonly is naturally so bright and pure on the surface, as to need no polishing; and when its figure will admit of being set without cutting, it is often worn in its rough state, and with no other than its native polish. Our jewellers are very nice, though not perfectly determinate, in their distinctions of this gem, knowing it in its different degrees of colour, under three different names: the first is simply the ruby, the name given it in its deepest coloured and most perfect state: the second is the spinel ruby; under this name they comprehend those rubies which are of a somewhat less bright colour than the ruby simply so called: the third is the balais ruby; under this name they express a pale yet a very bright ruby, with a less admixture of the purple tinge than in the deeper

coloured one; this is of less value than the deeper one.

We have the true ruby only from the East-Indies; and the principal mines of it are in the kingdom of Pegu and the island of Ceylon. We have in Europe crystals tinged to the colour of the ruby, but they have nothing of its lustre or hardness. The ruby seems to owe its colour to gold, it being possible to separate a small portion of gold from the little native rubies, and also to give the true colour of the ruby to fictitious paste by means of that metal.

The way of preparing a metalline colour from gold and tin, for the tinging glass of a ruby colour is, according to Shaw as follows: Dissolve gold in aqua-regia, and dilute the fine yellow solution with a large proportion of fair water; to the mixture add a sufficient quantity of a saturated solution of tin, made also in aqua-regia, at several times, and a most beautiful red or purple-coloured powder will soon fall to the bottom of the containing glass: decant the liquor and dry the powder, a few grains whereof being melted along with white crystalline glass will tinge it throughout of an extremely fine purple or ruby colour.

In M. Savary's Dict. de Commerce, we have the following table of the value of rubies, from one carat, or four grains, to ten carats:

|                              | l.  | s. | d. |
|------------------------------|-----|----|----|
| A ruby of one carat is worth | 1   | 15 | 00 |
| Of two                       | 9   | 00 | 00 |
| Of three                     | 22  | 10 | 00 |
| Of four                      | 33  | 15 | 00 |
| Of five                      | 45  | 00 | 00 |
| Of six                       | 67  | 10 | 00 |
| Of seven                     | 84  | 00 | 00 |
| Of eight                     | 106 | 00 | 00 |
| Of nine                      | 150 | 00 | 00 |
| Of ten                       | 216 | 00 | 00 |

**RUBY**, in heraldry, denotes the red colour where-with the arms of noblemen are blazoned; being the same which in the arms of others, not noble, is called gules. See the article GULES.

**RUCTATION**, **BELCHING**, a ventosity arising from indigestion, and discharging itself at the mouth with a very disagreeable noise. There are belches owing to repletion, and others to inanition, or emptiness. Quincy says hypochondriac and hysterical persons are particularly liable to this disorder. They are rather to be cured with proper stomachics than carminatives and hot liquors.

**RUDBECKIA**, **DWARF SUN-FLOWER**, in botany, a genus of plants, whose flower is compound and radiated, consisting of hermaphrodite, and female corollulæ; the hermaphrodite, which are tubulous and funnel-shaped, compose the disc in a conic form: the female corollulæ, which form the rays, are ligulated, and end in two or three indentures. There is no pericarpium, but the cup contains

tains, solitary, oblong, seeds, crowned with a membranaceous down, and fixed to a conic, paleaceous receptacle.

**RUDDER**, in navigation, a piece of timber turning on hinges in the stern of the ship, and which, opposing sometimes one side to the water and sometimes another, turns or directs the vessel this way or that. See **SHIP**.

The rudder of a ship is a piece of timber hung on the stern-posts by four or five iron-hooks, called pintles, serving as it were for the bridle of a ship to turn her about at the pleasure of the steers-man. The rudder being perpendicular; and without side the ship, another piece of timber is fitted to it at right angles, which comes into the ship, by which the rudder is managed and directed. This latter properly is called the helm or tiller; and sometimes, though improperly, the rudder itself. The power of the rudder is reduceable to that of the lever. See the article **LEVER**.

As to the angle the rudder should make with the keel, it is shewn, that in the working of ships, in order to stay or bear up the soonest possible, the tiller of the rudder ought to make an angle of  $55^{\circ}$  with the keel. A narrow rudder is best for a ship's sailing, provided she can feel it; that is, be guided and turned by it: for a broad rudder will hold much water when the helm is put over to any side; but if a ship have a fat quarter, so that the water cannot come quick and strong to her rudder, she will require a broad rudder. The aft-most part of the rudder is called the rake of the rudder.

**RUDENTURE**, in architecture, the figure of a rope or staff, sometimes plain, sometimes carved, with which the third part of the flutings of columns are frequently filled up.

**RUDIMENTS**, *Rudimenta*, the first principles or grounds of any art or science, called also the elements thereof. See the article **ELEMENT**.

**RUE**, *Ruta*, in botany. See the article **RUTA**.

**RUELLIA**, in botany, a genus of plants, whose flower is monopetalous and irregular; the tube is the length of the cup, with a patulous inclined neck; the limb spreads open, and is divided into five segments; the two upper ones are large and reflexed; the stamina are four filaments, placed in the spreading part of the tube, connected in pairs, and terminated with short antheræ. The fruit is a taper capsule pointed at each end, and containing two cells; which inclose a few roundish compressed seeds.

**RULE**, *Regula*, in matters of literature, a maxim, canon or precept, to be observed in any art or sciences.

The rules of philosophizing, of reasoning, of method, as also those to be observed in logic, morality, poetry, medicine, rhetoric, &c. have been already delivered under the articles **PHILOSOPHIZING**, **REASONING**, &c.

**RULE**, in arithmetic, denotes an operation performed with figures, in order to discover sums or numbers unknown.

The fundamental rules are addition, subtraction, multiplication, and division. See **ADDITION**, &c.

But besides these, there are other rules denominated from their use; as the rule of allegation, fellowship, interest, practice, reduction, &c. See the article **ALLEGATION**, &c.

**RULE OF THREE**, **GOLDEN RULE**, or **RULE OF PROPORTION**, is one of the most essential rules of arithmetic; for the foundation of which see the articles **GEOMETRICAL PROPORTION**.

It is called the Rule of Three from having three numbers given to find a fourth, but more properly the Rule of Proportion, because by it we find a fourth number proportional to three given numbers: and because of the necessary and extensive use of it, it is called the Golden Rule. But to give a definition of it with regard to numbers of particular and determinate things, it is the rule by which we find a number of any kind of things, as money, weight, &c. so proportional to a given number of the same things, as another number of the same or different things, is to a third number of the last kind of thing. For the four numbers that are proportional must either be all applied to one kind of things; or two of them must be of one kind, and the remaining two of another: because there can be no proportion, and consequently no comparison of quantities of different species, as for example, of three shillings and four days; or of six men and four yards.

All questions that fall under this rule may be distinguished into two kinds: the first contains these wherein it is simply and directly proposed to find a fourth proportional to three given numbers taken in a certain order: as if it were proposed to find a sum of money so proportioned to one hundred pounds as sixty four pounds ten shillings is to eighteen pounds six shillings and eight pence, or as forty pounds eight ounces is to six hundred weight. The second kind contains all such questions wherein we are left to discover, from the nature and circumstances of the question, that a fourth proportional is sought; and, consequently, how the state of the proportion or comparison of the terms, is to be made; which depends upon a clear understanding of the nature of the question and proportion. After the given terms are duly ordered, what remains to be done is to find a fourth proportional. But to remove all difficulty at much as possible, the whole solution is reduced to the following general rule, which contains what is necessary for solving such questions wherein the state of the proportion is given; in order to which it is necessary to premise these observations.

1. In all questions that fall under the following rule there is a supposition and a demand: two of the

the given numbers contain a supposition upon the conditions whereof a demand is made, to which the other given term belongs; and it is therefore said to raise the question; because the number sought has such a connection with it, as one of these in the supposition has to the other. For example; if 3 yards of cloth cost 4*l.* 10*s.* (here is the supposition) what are seven yards 3 quarters worth? here is the demand or question raised upon 7 yards 5 quarters, and the former supposition.

2. In the question there will sometimes be a superfluous term; that is, a term which, though it makes a circumstance in the question, yet it is not concerned in the proportion, because it is equally so in both the supposition and demand. This superfluous term is always known by being twice mentioned, either directly, or by some word that refers to it. Example, if 3 men spend 20*l.* in 10 days, how much, at that rate, will they spend in 25 days? Here the three men is a superfluous term, the proportion being among the other three given terms, with the number sought; so that any number of men may be as well supposed as 3.

Rule. First, the superfluous term (if there is one) being cast out, state the other three terms thus: of the two terms in the supposition, one is like the thing sought (that is, of the same kind of thing the same way applied); set that one in the second or middle place; the other term of the supposition set in the first place or on the left hand of the middle: and the term that raises the question, or with which the answer is connected, set in the third place, or on the right hand; and thus the extremes are like one another, and the middle term like the thing sought: also the first and second terms contain the supposition, and the third raises the question; so that the third and fourth have the same dependance or connection as the first and second. This done,

Secondly, Make all the three terms simple numbers of the lowest denominations expressed, so that the extremes be of one name. Then,

Thirdly, repeat the questions from the numbers thus stated and reduced, (arguing from the supposition to the demand) and observe whether the number sought ought to be greater or lesser than the middle term, which the nature of the question, rightly conceived, will determine; and accordingly, multiply the middle term by the greater or lesser extreme, and divide the product with the other, the quote is like the middle term, and is the complete answer, if there is no remainder; but if there is, then,

Fourthly, Reduce the remainder to the denomination next below that of the middle term, and divide by the same divisor, the quotient is another part of the answer in this new denomination. And if there is here also a remainder, reduce it to the next denomination, and then divide. Go on thus

to the lowest denomination, where, if there is a remainder, it must be applied fraction-wise to the divisor; and thus you will have the complete answer in a simple or mixed number.

Note, if any of the dividends is less than the divisor, reduce it to the next denomination, and to the next again, till it be greater than, or equal to, the divisor.

## EXAMPLES.

Question I. If 3 yards of cloth cost 8*s.* what is the price of 15 yards? Answer, 40*s.* or 2*l.*

Work. Explanation: 3 yards and 8*s.* contain the supposition, and 8*s.* is like the thing sought; therefore, 8*s.* is the middle term, and yards on the left: then the demand arises upon 15 yards, and therefore it is on the right. Again, from the nature of the question, it is plain, that 15 yards require more than 3 yards, i. e. the answer must be greater than the middle term; wherefore, 8*s.* is to be multiplied by 15 yards; the product is 120*s.* which, divided by 3 yards, quotes 40*s.* without a remainder; so 40*s.* or 2*l.* is the number sought.

Quest. II. If 4*lb.* of sugar cost 2*s.* 9*d.* what is the value of 18*lb.*? Answer, 12*s.* 4½*d.*

Work. Expl. The supposition is in 4*lb.* and 2*s.* 9*d.* this last term being like the thing sought, which is connected with 18*lb.* wherefore the terms are stated according to the rule: then the middle term being mixed, it is to be reduced to pence, and then argue thus: If 4*lb.* cost 33*d.* 18*lb.* must cost more; therefore, multiply 33*d.* by 18*lb.* and divide their product by 4; the quotient is 148*d.* and 2 remains, which is to be reduced to farthings, and the product divided by the former quotient, gives 2; so the answer is 148*d.* 2 farthings, or 12*s.* 4½*d.* because 148*d.* is, by reduction, 12*s.* 4*d.*

Quest. III. What is the price of 50*lb.* of tobacco, when 32*lb.* 12*oz.* cost 4*l.* 10*s.*? Answ. 6*l.* 17*s.* 4½*d.*

## Work.

R U M

When the wash is fully fermented, or to a due degree of acidity, the distillation is carried on in the common way, and the spirit is made up proof: though sometimes it is reduced to a much greater strength nearly approaching to that of the alcohol or spirit of wine, and it is then called double distilled rum. It might be easy to rectify the spirit, and bring

bring it to a much greater purity than we usually find it to be of; for it brings over in the distillation a very large quantity of the oil; and this is often so disagreeable that the rum must be suffered to lie by a long time to mellow before it can be used; whereas, if well rectified, it would grow mellow much sooner, and would have a much less potent flavour.

The best state to keep rum in, both for exportation and other uses, is doubtless that of alcohol, or rectified spirit. In this manner it would be transported in one half the bulk it usually is, and might be let down to the common proof-strength with water when necessary: for the common use of making punch, it would likewise serve much better in the state of alcohol; as the taste would be cleaner; and the strength might always be regulated to a much greater exactness than in the ordinary way.

The only use to which it would not so well serve in this state, would be the common practice of adulteration among our distillers; for when they want to mix a large portion of cheaper spirit with the rum, their business is to have it of the proof strength, and as full of the flavouring oil as they can, that it may drown the flavour of the spirits they mix with it, and extend its own. If the business of rectifying rum was more nicely managed, it seems a very practicable scheme to throw out so much of the oil, as to have it in the fine light state of a clear spirit, but lightly impregnated with it; in this case it would nearly resemble arrac, as is proved by the mixing a very small quantity of it with a tasteless spirit, in which case the whole bears a very near resemblance to arrac in flavour.

Rum is usually very much adulterated in England; some are so barefaced as to do it with malt-spirit; but when it is done with molasses-spirit, the tastes of both are so nearly allied that it is not easily discovered. The best method of judging of it is, by setting fire to a little of it; and when it has burnt away all the inflammable part examining the phlegm both by the taste and smell.

RUMEN, in comparative anatomy, the paunch, or first stomach of such animals as chew the cud, thence called ruminant animals.

The rumen is by far the largest of all the stomachs, and in it the whole mass of crude aliments, both solid and liquid, lies and macerates, to be thence transmitted to the mouth to be again chewed, comminuted, and fitted for farther digestion in the other ventricles. See the article DIGESTION.

RUMEX, the DOCK, in botany, a genus of plants whose flowers consist of three ovate connivent petals, with six very short capillary filaments topped with erect twin antheræ: there is no pericarpium, but the seed which is single and three-cornered, is included in the corolla.

This genus includes the *lapathum* and *acetosa* of Tournefort. See the articles *LAPATHUM* and *ACETOSA*.

RUMMAGE, in the sea language, signifies to clear a ship's hold or to remove goods from one place of it to another.

RUMPFIA, in botany, a genus of plants whose flower consists of a monophyllous, trifid cup, containing three oblong, obtuse and equal petals, with three subulated filaments, topped with small antheræ. The fruit is a coriaceous turbinate drupe, having three furrows, and contains an ovate trilobular nut, with a single three cornered kernel in each cell.

RUN, in the sea language, denotes so much of a ship's hull, as is under water.

RUNDLE, or ROUNDLE, in heraldry, the same with pellet.

RUNDLET, or RUNLET, a small vessel, containing an uncertain quantity of any liquor, from three to twenty gallons.

RUNIC, a term applied to the language and letters of the antient Goths, Danes, and other Northern nations.

RUNNER, in the sea language, a rope belonging to the garnet, and to the two bolt-tackles. It is reeved in a single block, joined to the end of a pennant, and has, at one end, a hook to hitch into any thing, and at the other end a double block, into which is reeved the fall of the tackle, or the garnet, by which means it purchases more than the tackle would without it.

RUNNET, or RENNET, the acid juice found in the stomach of calves, that have fed on nothing but milk, and are killed before the digestion is perfect.

RUNNING of Goods, a clandestine landing of goods, without paying the legal customs or duties for the same.

RUPEE, ROUPIA, or ROUPIAS, names of a gold and silver coin, current in the East-Indies.

RUPPIA, in botany, a genus of plants whose flower is without a corolla: the cup is an awl-shaped spadix; and the stamina consists of four sessile, roundish, erect, half-twin antheræ. There is no pericarpium; but the seeds, which are four or five in number, are ovate and oblique, are terminated by a plain stigmata.

RUPTURE, in surgery, the same with hernia. See the article HERNIA.

RUPTURE-WORT, *Herniaria*, in botany. See the article HERNIARIA.

RURAL, or RUSTIC, in general, denotes something that relates to the country.

RURAL DEAN, in church-history. See the article DEAN.

RUSCUS, knee-holly, or butcher's-broom, in botany, a genus producing male and female flowers on distinct plants: the flower cup is divided into six ovate convex segments; the perals are wanting; but each have an oval, erect, inflated nectarium opening at its mouth. in the male flower,

are

are placed on the top of the nectarium and joined at their base, three spreading antheræ. The female flower contains an oblong oval germen supporting a cylindraceous style, which is crowned with an obtuse stigma standing above the mouth of the nectarium; the fruit is a globose, trilocular berry, containing two round seeds.

There are several species of *ruscus*; the common sort which grows wild in the woods, in many parts of England, is of an austere and bitterish taste, and accounted aperient and deterfive.

Boerhaave, affirms, the decoction of the leaves in white wine, is an excellent remedy in the gravel and dropsy: the root is one of the five great opening roots.

**RUSH**, *juncus*, in botany, a genus of plants, whose flower hath no corolla: but the perianthium, when fresh and coloured, much resembles one: the stamina are six very short capillary filaments topped with oblong erect antheræ. The fruit is a close, triqueous capsule with one cell, and opening with three valves, and contains several roundish seeds.

There are several species of rush growing in England in moist places; also on the sea shore, particularly in Holland, where they are planted with great care, in order to prevent the water from washing away the earth, which being very loose, would be in danger of removing every tide, if it were not for the roots of these rushes, which fasten themselves very deep in the ground, and mat near the surface, so as to hold the earth closely together. Therefore, whenever the roots of these rushes are destroyed, they are immediately repaired to prevent farther damage. In the summer time, when the rushes are fully grown, the inhabitants cut them and tie them up in bundles, which are dried, and afterwards carried into the larger towns and cities, where they are wrought into baskets, and several other useful things, which are frequently sent into England.

*Sweet-RUSH.* See **ACORNS**.

**RUST** of a *Metal*, the flower or calx thereof, procured by corroding and dissolving its superficial parts by some menstruum. Water is the great instrument or agent in producing rust; and hence oils, and other fatty bodies, secure metals from rust; water being no menstruum to oil, &c. and therefore not able to make its way through it.

All metals are liable to rust, even gold itself, if exposed to the fumes of sea salt.

**RUST**, or **BLIGHT** of *Corn*. See **BLIGHT**.

**RUSTIC**, in architecture, implies a manner of building in imitation of nature, rather than according to the rules of art.

**RUSTIC-WORK**, is where the stones in the face, &c. of a building, instead of being smooth, are hatched, or picked with a point of a hammer.

**RUSTIC-ORDER**, that decorated with rustic quoins, rustic work, &c.

**RUSTRE**, in heraldry, a bearing of a diamond-shape, pierced through in the middle with a round hole.

**RUT**, in hunting, the venery or copulation of deer.

**UTA**, *rue*, in botany, a genus of plants whose flower consists of five patent oval petals, with narrow unguis; the stamina are ten subulated spreading filaments, topped with erect and short antheræ. the fruit is a gibbous capsule, with five lobes and five cells opening in five parts at the top, and contains many rough angulated seeds.

The common garden *rue* may be propagated either by slips or cuttings in the spring, or from seeds; it has a disagreeable smell, with an acrid bitter taste; the leaves, when in perfection, will blister the skin if much handled; and are said to be inciding, attenuant, and discutive.

It is commended as an alexipharmic and cephalic, and prescribed in hysterics and nervous complaints. *Rue* is replete with a fat viscous juice, and therefore yields little to any good purpose in distillation, unless when first digested in a spirituous menstruum. The best way of taking it, is the leaves fresh gathered, for those who can bear the taste; or they may be taken in powder from a scruple to a dram, or the infusion may be drank as tea.

**Goats-RUE**, *Galega*, in botany, a plant producing papilionaceous flowers; the root is slender, woody, white, fibrous, and perennial; the stalks arise two or three feet high, and are hollow, streaked, and divided into several branches; the leaves are winged, and composed of six or seven pair of lobes, terminated by an odd one. The flowers grow in spikes at the ends of the stalks, and are of a pale blue colour; they appear in June, and are succeeded by taper pods about an inch and a half long, and contain in each a row of kidney-shaped seeds.

This plant is used in medicine, and is accounted cordial, sudorific, and alexipharmic, and has been commended in pestilential fevers; it may be eaten either crude or boiled, or a spoonful of the juice may be given for a dose.

*Meadow RUE*, *Thalictrum*. See the article **THALICTRUM**.

*Wall-RUE*, *Ruta Muraria*, a species of asplenium. See **ASPENIUM**.

*Wild-RUE*, *Harmala*, or *Peganum*. See the article **PEGANUM**.

**RYE**, *Secale*, in botany, a gramineous plant, whose root is furnished with slender fibres, and from which arises several stalks, having four or five knots with a few long narrow leaves, that are reddish when they spring out of the ground; the flower-corolla consists of two valves; the exterior valve

# R Y E

is rigid, ventricose, acuminate, and compressed; its lower edge is ciliated, and terminating in a long arista; the interior valve is lanceolated and plain; the nectaria are two, ovated and erect; the filaments are three, hairy, and hanging without the flower; these are terminated by oblong forked antheræ; the corolla serves the office of a pericarpium, inclosing the seed, and at a proper time opening and dropping it out; the seed is single, oblong, and almost cylindric. The spikes, or ears, of rye are longer and flatter than those of wheat, and flowers in May. The farmers distinguish two sorts of this plant, by the titles of winter and spring rye; but it is the winter sort which is principally propagated; it is usually sown about the beginning of September, on such poor land as wheat will not thrive on, and in dry weather, if possible; two bushels of seed is generally allowed to an acre; but if the ground be newly broke up, or subject to worms, then a peck more is commonly allowed; a little sprinkling of dung or mud upon rye-land will greatly advance the crop, though it is laid but half the thickness that it is for other corn: its produce is commonly about twenty bushels upon an acre.

# R Y S

The general use of rye is for bread, either alone or mixed with wheat; but is only fit for those persons who have always been used to it.

Rye is reckoned more detergent than any other grain of which bread is made. It is by some used in suppurative and discutient cataplasms, and not always without success to the parts affected with the gout.

**RYE-GRASS**, a species of hordeum. See **HORDEUM**. It is common to mix clover and rye-grass together, allowing ten pounds of clover and one bushel of rye-grass to an acre; but this is only to be done where the land is designed to remain but three or four years in pasture, as neither the rye-grass or clover are of long duration; and it certainly is a wrong, though too general practice, to sow rye-grass with barley, for the corn must considerably draw away the nourishment from the grass, so as to leave but half a crop of grass when the barley is off the ground.

**RYME**, or **RHYME**. See **RHYME**.

**RYSAGON**, a name given to the cassumunar-root. See **CASSUMUNAR**.

# S.

## S A B

**S**, The eighteenth letter, and fourteenth consonant of our alphabet; the sound of which varies, being strong in some words, as *this*, *thus*, &c. and soft in words which have a final *e*, as *mus*, *wise*, &c. It is generally doubled at the end of words, whereby they become hard and harsh, as in *kiss*, *lass*, &c. In some words it is silent, as *isle*, *island*, *viscount*, &c. In writing, or printing, the long character *s*, is used at the beginning and middle of words, but the short *s*, at the end.

In abbreviations, *S*. stands for *societas*, or *socius*, as, *R.S.S.* for *regiæ societatis socius*, i. e. fellow of the royal society. In medicinal prescriptions, *S.A.* signifies *secundum artem*, i. e. according to the rules of art. Used as a numeral, *S*, anciently denoted seven.

**SABÆANS**, in church history, a set of idolators, much more ancient than the Jewish law.

In the early ages of the world, idolatry was divided between two sects; the worshippers of images, called Sabæans, or Sabians, and the worshippers of fire, called Magi. See **MAGI**.

The Sabæans began with worshipping the heavenly bodies, which they imagined were animated by inferior deities. In the consecration of their images, they used many incantations to draw down into them from the stars, those intelligences for whom they erected them, whose power and influence, they held, afterwards dwelt in them.

This religion, it is said, first began among the Chaldæans, with their knowledge in astronomy; and from this it was, that Abraham separated himself, when he came out of Chaldæa. From the Chaldæans it spread all over the East; and from thence to the Grecians, who propagated it to all the nations of the known world.

The remainder of this sect still subsists in the East, and pretend to derive their name from Sabius, a son of Seth; and among the books in which the doc-

## S A B

trines of this sect are contained, they have one which they call the Book of Seth, and which, they pretend, was written by that patriarch.

**SABBATH**, or the day of rest, a solemn festival of the Jews, on the seventh day of the week, or Saturday, beginning from sun-set on Friday, to sun-set on Saturday.

The observation of the sabbath began with the world; for God, having employed six days in its creation, appointed the seventh as a day of rest, to be observed by man, in commemoration of that great event.

On this day, the Jews were commanded to abstain from all labour, and to give rest to their cattle. They were not allowed to go out of the city farther than two thousand cubits, or about a mile; a custom which was founded on the distance of the ark from the tents of the Israelites, in the wilderness, after their leaving Egypt; for being permitted to go, even on the sabbath-day, to the tabernacle to pray, they from thence inferred, that the taking a journey of no greater length, though on a different account could not be a breach of the sabbatical rest.

As the seventh day was a day of rest to the people, so was the seventh year to the land; it being unlawful in this year to plow or sow, and whatever the earth produced, belonged to the poor; this was called the sabbatical year.

The modern, as well as the antient, Jews, are very superstitious in the observance of the sabbath; they carry neither arms, nor gold, nor silver about them, and are permitted neither to touch these, nor a candle, nor any thing belonging to the fire; on which account they light up lamps on Friday, which burn till the end of the sabbath.

There is at present a sect of baptists called sabbatarians, from their observing the seventh day of the week, as a day set apart for the worship of God; they

they attempt to justify this practice by alledging that the Jewish sabbath was never abrogated in the New Testament; and that where God has given a command, it is our duty to observe it till he has abrogated or altered it by a new command. See the article SUNDAY.

**SABELLIANS**, a sect of christians of the III<sup>d</sup> century, that embraced the opinions of Sabellius, a philosopher of Egypt, who openly taught that there is but one person in the Godhead.

The Sabellians maintained, that the Word and the Holy Spirit are only virtues, emanations, or functions of the Deity; and held that he who is in heaven is the father of all things, descended into the virgin, became a child, and was born of her as a son; and that having accomplished the mystery of our salvation, he diffused himself on the apostles in tongues of fire, and was then denominated the Holy-Ghost. This they explained by resembling God to the sun, the illuminative virtue or quality of which was the Word, and its warming virtue the Holy Spirit. The Word, they taught, was darted, like a divine ray, to accomplish the work of redemption; and that being reascended to heaven, the influences of the Father were communicated after a like manner to the apostles.

**SABLE**, in heraldry, denotes the colour black, in coats of arms belonging to gentlemen; but in those of noblemen it is called diamond; and in those of sovereign princes, saturen.

It is expressed in engraving, by perpendicular and horizontal hatches crossing one another.

**SABRE**, a kind of sword, or scimiter, with a very broad and heavy blade, thick at the back, and a little falcated or crooked towards the point.

It is the ordinary weapon worn by the Turks, who are said to be very expert in the use of it.

**SAC**, in law, is said to be an ancient privilege, which the lord of a manor claims of holding his court, in causes of trespass among his tenants, and imposing fines for the same.

**SACCHARUM-SATURNI**, sugar of lead, for the preparation of which, see SUGAR of Lead.

Some have ventured to give sugar of lead internally, in doses of a few grains, as a styptic, in hæmorrhages, profuse colliquative sweats, seminal fluxes, the fluor albus, &c. and, indeed, it must be allowed, that it very powerfully restrains the discharge; but then it occasions other symptoms, often dangerous, and sometimes fatal, as violent colic pains, obstinate constipations, cramps, tremors, &c. so that its internal use seems by no means innocent.

**SACCO BENITO**. See INQUISITION and ACT of faith.

**SACCULUS**, in anatomy, a diminutive of *saccus*, signifies a little bag: as, 1. The *sacculus lacrymalis*, which is a little bag, into which the puncta lacrymalia of the eye open. 2. The *sacculus cordis*, or pericardium. 3. The *sacculus chyloferus*, the beginning of the thoracic duct, more usually called

*receptaculum chyli*. 4. *Sacculi adiposi*, or the adipose cells, &c. See the article EYE, PERICARDIUM, RECEPTACULUM, &c.

A topical application, inclosed in a linen bag, is also termed *sacculus medicinalis*; as is a bag filled with medicinal simples, and suspended in a liquor, in order to make a diet-drink.

**SACCUS JUGULARIS**, the jugular-sack, in anatomy, a receptacle formed at the termination of the internal jugular vein; the use of which is to bring back the blood from the sinuses of the dura mater, and from the brain. See the article JUGULAR and BRAIN.

**SACERDOTAL**, something belonging to priests. See the article PRIEST.

**SACK of wool**, a quantity of wool containing just twenty-two stone, and every stone fourteen pounds. In Scotland, a sack is twenty-four stone, each stone containing sixteen pounds.

**SACK of Cotton-wool**, a quantity from one hundred and a half to four hundred weight.

**SACKS of Earth**, in fortification, are canvas bags filled with earth. They are used in making retrenchments in haste, to place on parapets, or the head of the breaches, or to repair them, when beaten down.

**SACKBUT**, a musical instrument of the wind-kind, being a sort of trumpet, though different from the common trumpet, both in form and size: it is fit to play a bass, and is contrived to be drawn out, or shortened, according to the tone required, whether grave or acute. The Italians call it *trombone*, and the Latins *tuba ductilis*.

It takes asunder in four pieces, and has frequently a wreath in the middle, which is the same tube only twice twisted, or making two circles in the middle of the instrument, by which means it is brought down one fourth lower than its natural tone; it has also two pieces of branches on the inside, which do not appear, unless drawn out by an iron-bar, and which lengthens it till it hit the tone required.

The sackbut is usually eight feet long, without reckoning the circles, and without being drawn out: when it is extended to its full length, it is usually fifteen feet; the wreath is two feet nine inches in circumference.

There are sackbuts of different sizes, distinguished by the epithets *primo* or I°, *secundo* or II°, *terzo* or III°, &c. or I°, 2°, 3°, &c.

**SACRA**, the SACRED ARTERY, in anatomy, is a branch of the aorta descendens; which, according to Heister, sometimes descends through the os sacrum to the pelvis; sometimes arises one from each iliac, and sometimes is altogether wanting.

There is also a vein called the *vena sacra*, which arises from the *vena cava*, just above the iliacs: it is sometimes double.

**SACRAMENT**, *Sacramentum*, signifies, in general, a sign of a thing sacred and holy; and is defined to be an outward and visible sign of a spiritual grace.

grace. Thus there are two objects in a sacrament, the one the object of the senses, and the other the object of faith. Protestants admit only of two sacraments, baptism, and the eucharist, or Lord's supper: but the Roman-catholics own seven, viz. baptism, confirmation, the eucharist, penance, extreme unction, ordination, and marriage. See the articles **BAPTISM, CONFIRMATION, &c.**

The romanists, however, by way of eminence, call the eucharist the holy sacrament. Thus to expose the holy sacrament, is to lay the consecrated host on the altar to be adored. The procession of the holy sacrament, is that in which this host is carried about the church, or about a town.

**SACRAMENT** was also used in the Roman law for a pledge in money, which both the plaintiff and defendant in a real action laid down in court to be forfeited by him who shall lose the cause.

**SACRAMENTARIANS**, a name given by the romanists to all such as, in their opinion, entertain erroneous doctrines of the sacrament of the Lord's supper, and chiefly used by way of reproach to Lutherans, Calvinists, and other protestants.

**SACRAMENTARY**, an antient romish church-book, which contains all the prayers and ceremonies practised at the celebration of the sacraments.

It was wrote by pope Gelasius, and afterwards revised, corrected, and abridged by St. Gregory.

**SACRED**, something holy, or that is solemnly offered and consecrated to God, with benedictions, unctions, &c. Thus kings and priests are held sacred persons; the deaconhood, sub-deaconhood, and priesthood, are all sacred orders, and impress a sacred indelible character. The sacred college is that of the cardinals.

Sacred is also applied to things belonging to God and the church. Thus churches, church-lands, ornaments, &c. are held sacred. But, in civil law, a sacred place chiefly denotes, that where a person deceased has been interred.

Sacred majesty is applied to the emperor and the king of England; though this title has by some been thought blasphemous.

**SACRIFICE**, a solemn act of religious worship, which consisted in dedicating or offering up something animate or inanimate on an altar, by the hands of the priest, either as an expression of their gratitude to the deity for some signal mercy, or to acknowledge their dependance on him, or to conciliate his favour. The origin of sacrifices is by some ascribed to the Phœnicians, but Porphyry ascribes it to the Egyptians, who first offered the first fruits of their grounds to the gods, burning them upon an altar of turf: thus in the most antient sacrifices there were neither living creatures, nor any thing costly or magnificent; and no myrrh or frankincense. At length they began to burn perfumes; and afterwards men leaving their antient diet of herbs and roots, and beginning to use living crea-

tures for food, they began also to change their sacrifices. The scriptures, however, furnish us with a different account; for Noah, it is said, sacrificed animals at his coming out of the ark; and even Abel himself sacrificed the best and fattest of his flock; but Grotius thinks it more probable that he contented himself with making a mere oblation of his lambs, &c. without slaying them.

The Jews had two sorts of sacrifices, taking the word in its largest signification: the first were offerings of tythes, first-fruits, cakes, wine, oil, honey, and the like; and the last, offerings of slaughtered animals. When an Israelite offered a loaf or a cake, the priest broke it in two parts, and setting aside that half which he reserved for himself, broke the other into crumbs, poured oil, wine, incense, and salt upon it, and spread the whole upon the fire of the altar. If these offerings were accompanied with the sacrifice of an animal, they were thrown upon the victim to be consumed along with it. If the offerings were of the ears of new corn, they were parched at the fire, rubbed in the hand, and then offered to the priest in a vessel, over which he poured oil, incense, wine and salt, and then burnt it upon the altar, having first taken as much of it, as of right belonged to himself.

The principal sacrifices among the Hebrews consisted of bullocks, sheep and goats; but doves and turtles were accepted from those who were not able to bring the other; these beasts were to be perfect and without blemish. The rites of sacrificing were very various, all of which are minutely described in the books of Moses.

The manner of sacrificing among the Greeks and Romans was as follows: in the choice of the victim, they took care that it was without blemish or imperfection; its tail was not to be too small at the end; the tongue not black, nor the ears cleft; and that the bull was one that had never been yoked. The victim being pitched upon, they gilt his forehead and horns, especially if a bull, heifer, or cow. The head they also adorned with a garland of flowers, a woollen infula or holy fillet, whence hung two rows of chaplets with twisted ribbands; and on the middle of the body a kind of stole, pretty large, hung down on each side; the lesser victims were only adorned with garlands and bundles of flowers, together with white tufts or wreaths.

The victims thus prepared, were brought before the altar; the lesser being driven to the place, and the greater led by an halter; when if they made any struggle, or refused to go, the resistance was taken for an ill omen, and the sacrifice frequently was set aside. The victim thus brought, was carefully examined, to see that there was no defect in it: then the priest, clad in his sacerdotal habit, and accompanied with the sacrificers and other attendants, and being washed and purified according to the ceremonies prescribed, turned to the right hand and

and went round the altar, sprinkling it with meal and holy-water, and also besprinkling those who were present. Then the cryer proclaimed with a loud voice, Who is here? To which the people replied; Many and good. The priest then having exhorted the people to join with him by saying, Let us pray, confessed his own unworthiness, acknowledging that he had been guilty of divers sins; for which he begged pardon of the gods, hoping that they would be pleased to grant his requests, accept the oblations offered them, and send them all health and happiness; and to this general form added petitions for such particular favours as were then desired. Prayers being ended, the priest took a cup of wine, and having tasted it himself, caused his assistants to do the like; and then poured forth the remainder between the horns of the victim. Then the priest, or the cryer, or sometimes the most honourable person in the company, killed the beast, by knocking it down, or cutting its throat. If the sacrifice was in honour of the celestial gods, the throat was turned up towards heaven; but if they sacrificed to the heroes or infernal gods, the victim was killed with its throat towards the ground. If by accident the beast escaped the stroke, leaped up after it, or expired with pain and difficulty, it was thought to be unacceptable to the gods. The beast being killed, the priest inspected its intrails, and made predictions from them. They then poured wine, together with frankincense, into the fire, to increase the flame, and then laid the sacrifice on the altar; which in the primitive times was burnt whole to the gods, and thence called an holocaust; but in after-times, only part of the victim was consumed in the fire, and the remainder reserved for the sacrificers; the thighs and sometimes the entrails being burnt to their honour; the company feasted upon the rest. While the sacrifice was burning, the priest, and the person who gave the sacrifice, jointly prayed, laying their hands upon the altar. Sometimes they played upon musical instruments in the time of the sacrifice, and on some occasions they danced round the altar, singing sacred hymns in honour of the gods.

**SACRILEGE**, the crime of profaning sacred things, or those devoted to the service of God.

**SACRISTAN**, *Sacrista*, a church officer, otherwise called sexton.

**SACRISTY**, *Sacristia*, in church history, an apartment in a church, where the sacred utensils were kept; being the same with our vestry.

**SACRO LUMBARIS**, in anatomy, one of the exterior muscles of the back and loins, has its origin at the os sacrum and the posterior spine of the ilium, and its termination in the upper part of the ribs.

**SACRUM** Os, the sacred bone, in anatomy, the lower extremity of the spina dorsi, being a bone, of a triangular figure, with a rough surface; its

substance is spongy, and it has two lateral apophyses for its articulation with the ossa innominata; also two smaller upper apophyses, with glenoid cavities for the articulation into the lower vertebra; and an inferior apophyses, for its articulation with the os coccygis: it has also a canal for the end of the spinal marrow.

**SADDLE**, is a seat upon a horse's back, contrived for the conveniency of the rider.

**SADDLE-GALLEC**, in farriery. See the article **GALLING**.

**SADDUCEES**, in Jewish antiquity, a famous sect among the ancient Jews, so called from their founder Sadoc Antigonus of Socho, president of the sanhedrim at Jerusalem, and teacher of the law in the principal divinity-school of that city. Having often, in his lectures, asserted to his scholars, that they ought not to serve God in a servile manner, with respect to reward, but only out of filial love and fear; two of his scholars, Sadoc and Baithus, inferred from thence, that there were no rewards or punishments after this life: and, therefore, separating from the school of their master, they taught that there was no resurrection, nor future state. Many embracing this opinion, gave rise to the sect of the Sadducees, who were a kind of Epicureans, but differing from them in this, that though they denied a future state, yet they allowed the world was created by the power of God, and governed by his providence; whereas the followers of Epicurus denied both.

The Sadducees denied all manner of predestination whatever, and not only rejected all unwritten traditions, but also all the books of the Old Testament, excepting the pentateuch.

**SAFE CONDUCT**, a security given by the king under the great seal to a foreigner, for his safe coming into and passing out of the kingdom.

**SAFE-GUARD**, a protection formerly granted to a stranger who feared violence from some of the king's subjects, for seeking his right by course of law.

**SAFFRON**, *Crocus*, in botany, &c. See the article **CROCUS**.

**SAFFRON**, *Crocus*, is also a name given to several chemical preparations, from their resembling the vegetable saffron in colour. See the article **CROCUS**.

**Meadow-SAFFRON**, *Colchicum*, in botany, &c. See the article **COLCHICUM**.

**SAGAPENUM**, in pharmacy, &c. a gum-resin, brought to us in two forms; the finer and purer is in loose granules, or single drops; the coarser kind is in masses composed of these drops of various sizes, cemented together by a matter of the same kind. In either case it is of a firm and compact substance, considerably heavy, and of a reddish colour on the outside, brownish within, and spotted in many places with small yellowish or whitish specks. Its smell is strong and disagreeable; its taste acrid and unpleasant.

Sagapenum is a very great attenuant, aperient and discutient; it is good in all disorders of the breast that owe their origin to a tough phlegm. It has also been found to discuss tumours in the nervous parts, in a remarkable manner, and to give relief in habitual head-achs, where almost all things else have failed. Its dose is from ten grains to two scruples, but it is now seldom given alone. It has been found, however, to do great things in asthmas, in obstructions of the viscera, particularly the spleen, in nervous complaints, and even in epilepsies. It also promotes the menses, and expels the secundines; and is an ingredient in the theriaca, mithridate, and many other of the shop compositions.

SAGATHEE, in commerce, a slight kind of woollen stuff, serge, or ratteen, sometimes mixed with a little silk.

SAGE, *Salvia*, in botany, a genus of plants, whose flower is monopetalous, and tubular ringent at the mouth; the upper-lip concave, compressed, incurved, and emarginated; the lower-lip is broad and trifid; there is no pericarpium, but the seeds, which are roundish, and four in number, are contained in the bottom of the cup. There are several species of sage, the most common are the red sage, green sage, sage of virtue, or narrow-leaved sage, and sage with variegated leaves; these are propagated by slips, which should be planted in April, in a shady border of light rich earth; and when sufficiently rooted, may be transplanted where they are intended to remain; which should be in a dry soil, as they are apt to be destroyed in hard winters if planted in moist land.

Sage is accounted cephalic and sudorific; it is very good against the apoplexy, epilepsy, palsy,

and trembling of the limbs; it is used in the manner of tea, against any of the abovementioned disorders, as well as for a preservative. It is very good for disorders of the brain, to promote the circulation of the fluids, to strengthen the stomach, and to promote digestion; it has an austerity on the palate; and makes a very good gargarism, if sharpened with a little acid. It is commonly said, that the Chinese wonder we should buy their tea, when we have so much sage, which they reckon more excellent.

As to external use, the leaves and flowers are often employed in fomentation, to strengthen the nerves, and to discuss the swelling of wounds.

To this genus Linnæus has added the *horminum* and *felarea* of Tournefort.

*Wild SAGE.* See TEUCRUM.

*SAGE of Jerusalem.* See PHLOMIS.

SAGENE, a Russian long measure, five hundred of which make a werst: the sagene is equal to seven English feet.

SAGINA, in botany, a genus of plants, whose flower consists of four ovate, obtuse, and patent petals, with four capillary filaments, topped with roundish antheræ. The fruit is an ovate, quadricocular capsule, opening with four valves, and containing numerous small seeds affixed to the receptacle.

SAGITTA, in astronomy, the arrow, or dart, a constellation of the northern hemisphere, near the eagle; consisting of five stars, according to Ptolemy and Tycho; but in Mr. Flamsteed's catalogue, of no less than twenty-three. The latitude and longitude of which are as follow.

| Names and Situations of the Stars.     |  |  |  |  | Signs. | Longitude | Latitude North. | Mag. |
|----------------------------------------|--|--|--|--|--------|-----------|-----------------|------|
|                                        |  |  |  |  | ♈      | 21. 08    | 43. 7.45        | 6    |
|                                        |  |  |  |  |        | 21. 20.24 | 43. 15.10       | 6    |

SAGITTA, in botany, implies the top of any small twig, cyon, or graft of a tree.

SAGITTA, in trigonometry, the same with the versed sine of an arch.

SAGITTAL, *Suture*, in anatomy, the second of the genuine sutures of the cranium or skull.

SAGITTARIA, arrow-head, in botany, a genus of aquatic plants, producing male and female flowers on the same plant; the male corolla consists of three roundish, obtuse, plane, patent petals, thrice the length of the cup, with a great number of stamina; the female corolla is like that of the male; there is no pericarpium; the receptacle, which is globose, collects the seeds into a head; the seeds are numerous, oblong, compressed, and surrounded longitudinally with a broad membranaceous border.

Arrow-head grows naturally in standing waters, in most parts of England; the root is composed of strong fibres which strike deep in the mud; the footstalks of the leaves are of the depth of the water where they grow, the leaves laying flat on the surface, and are shaped like the point of an arrow; the two ears at their base spreading wide asunder. The flowers come out in July, and are produced on long stalks rising above the leaves, and standing in whorls round the joints, and are of a white colour.

SAGITTARIUS, the archer, in astronomy, the ninth sign of the zodiac. See the article ZODIAC.

The stars in this constellation in Ptolemy's catalogue are thirty-two, in Tycho's sixteen, and in Mr. Flamsteed's fifty; the latitude and longitude of which are as follow. (See plate LXXIX.)

50.

SAGO, a simple brought from the East-Indies, of considerable use in diet as a restorative.

SAICK, or SAIQUE, a Turkish vessel, very common in the Levant, for carrying of merchandise.

SAIL, in navigation, an assemblage of several breadths of canvas, sewed together by the lifts, and edged round with a cord, fastened to the yards of a ship, to make it drive before the wind.

SAILS also denote the vanes of wind-mills. See the article WIND-MILL.

SAILING, properly denotes the art of navigating and working a ship, or of causing her to observe such motions and directions as are assigned by the navigator; in which sense, sailing differs from navigation, and must be learned by practice on ship-board.

The most advantageous position of the sails and rudder of a ship, has been already treated of under the article MAXIMUM; which see.

SAILING, also denotes a particular method of navigation; in which sense we say, great-circle sailing, Mercator's sailing, middle-latitude sailing, parallel sailing, and plain or plane sailing.

Great-Circle SAILING, in navigation, the art of finding what places a ship must go through, and what courses to steer; so that her tract shall be in the arch of a great-circle, or nearly so, passing thro' the place sailed from and that bound to.

It is chiefly on account of the shortest distance, that this method of sailing has been proposed; for in the sphere, it is well known, that the shortest distance between two places is the arch of a great circle intercepted between them, and not in the rhumb or spiral passing through those places. See the article RHUMB.

Mercator's SAILING, is the method of navigating a ship on the principles laid down by our countryman Mr. Wright, and falsely ascribed to Mercator. It consists in projecting a sea-chart on a plane, so that

that the crooked spiral lines on the globe, become right-lines in the projection, and still in the same proportion with the curve lines on the globe.

*Middle-Latitude SAILING*, is the method of keeping an account of a ship's way, by computing the miles or longitude on the parallel of the middle latitude; as that parallel which is equally distant from the latitude she departed from, and that under which she is arrived.

*Parallel SAILING*, is the method of conducting a ship when sailing due east or west, under any parallel of latitude.

*Plain or Plane SAILING*, is the method of navigating a ship which supposes the earth to be an extended plane, and the meridians and parallels of latitude at equal distances from one another.

*SAILORS*, the elder seamen, who are employed in working or managing the sails, the tackle, steering, &c. See *NAVAL Affairs*, *SEAMEN*, &c.

*SAINT*, in the Romish church, a holy person deceased, and since his decease canonized by the pope, after several informations and ceremonies.

*SAINT John's-Wort*, *Hypericum*, in botany. See *HYPERICUM*.

*SAINT Peter's-Wort*, *Ascyrum*, in botany. See *ASCYRUM*.

*SAINT-FOIN*, *Anabrychis*, in botany, a plant much esteemed for foddering cattle.

The best season for sowing it is in April, taking the advantage of dry weather; the common quantity allowed, is four bushels to the acre: the first year it should not be fed, for the crown of the root being young and tender, the cattle would eat it so low, as entirely to destroy the roots; and if large cattle were admitted on it, they would trample it down so much as to prevent its shooting again; therefore, it should be mowed the first year, when it is in flower, and made into hay.

This sort of hay is exceeding good for horses, and is esteemed one of the best sorts of food for most cattle, especially in the spring, there being no danger attending it, as there is in clover and some other sorts of fodder; it breeds abundance of milk, and the butter that is made of it is very good.

The proper soil for faint-foin, is a dry, gravelly, or chalky ground, on which it will continue eighteen or twenty years without renewing.

*SAKER*, a small sort of cannon, whereof there are three species, extraordinary, ordinary, and middle-sized. See the article *CANNON*.

*SAL*, in chemistry, &c. the same with salt. See the article *SALT*.

*SALAMANDER*, *Salamandra*, in zoology, a name given by authors to several species of the lizard kind; but the principal are two, the salamandra-aquatica (the water-newt) and the salamandra-terrestris.

The salamandra-aquatica is the two-edged-tailed lizard, with four toes on the anterior, and five on

the hinder, feet: it grows to about four inches in length, and to the thickness of a man's finger; the back is of a deep shining brown, and the belly of a bright glossy yellow.

The salamandra-terrestris, or land salamander, is a species of lizard, the tail of which is short, and its colour of a fine black, marked with red spots of a bright and shining glossy appearance.

*SALAMANDER's-Blood*, among chemists, denotes the redness remaining in the receiver, after distilling the spirit of nitre.

*SALARY*, *Salarium*, a recompence made to a person, for his pains or industry about another person's business, as in the case of officers, &c. And it is generally taken for any wages, stipend, or allowance.

*SALE*, in general, signifies the transferring the property of goods, from one to another, upon some valuable consideration; as where, in a bargain, one agrees to give another a certain sum of money for such goods, and thereupon gives the seller earnest, which he accepts; this is a perfect sale, and shall bind the buyer and seller.

*SALEP*, in the materia medica, the root of a species of orchis. See the article *ORCHIS*.

Salap should be chosen clean, firm, and hard; it is very little liable either to decay or sophistication. The salep differs very little from the common orchis in virtue. Its appearance is owing to the manner of preparing it, and consequently this may be done from the roots of orchis of our own growth.

To prepare these in imitation of salep, Mr. Geoffroy chose the largest, fairest, and plumpest roots he could find: these he nicely skinned; then throwing them into cold water, he suffered them to macerate there for some time: after this, he lightly boiled them; and then, taking them out of the water and draining them, he had them strung upon threads, to be dried in a warm dry air: when the roots were thoroughly dried, they were very transparent, and resembled pieces of tragacanth, and continued dry and hard.

The roots thus prepared may be reduced to powder, which will dissolve away in boiling water, and a scruple of it will make a basin full of jelly, in the manner of the Turkish salep.

This jelly is an admirable medicine in all cases in which salep is prescribed; and the powder may be given with great success in asses-milk, for diseases of the breast. The people of the East-Indies look upon salep to be one of the greatest restoratives and provocatives to venery in the whole vegetable world. The salep which we receive from Turkey is always a transparent root, of a whitish or reddish colour, according to its different age, and is chiefly recommended in consumptions, bilious dysenteries, and disorders of the breast, proceeding from an acrimony of the juices.

*SALET*, *SALLET*, or *SALADE*, in war, a light covering

covering or armour for the head, anciently worn by the light-horse, only differing from the casq in that it had no crest, and was little more than a bare cup.

**SALIENT**, in fortification, denotes projecting. There are two kinds of angles, the one salient, which are those that present their points outward; the other re-entering, which have their points inward. Instances of both kinds we have in tenailles and star-works.

**SALIENT**, **SALIENT**, or **SAILLANT**, in heraldry, is applied to a lion, or other beast, when its fore-legs are raised in a leaping posture.

**SALIC**, or **SALIQUE LAW**, *Lex Salica*, an ancient and fundamental law of the kingdom of France, usually supposed to have been made by Pharamond, or at least by Clovis, in virtue whereof males are only to inherit.

Du Haillan, after a critical examination, declares it to have been an expedient of Philip the Long, in 1316, for the exclusion of the daughter of Lewis Hutin from inheriting the crown. Father Daniel, on the other hand, maintains that it is quoted by authors more ancient than Philip the Long, and that Clovis is the real author of it.

This law has not any particular regard to the crown of France; it only imports, in general, that in salic land no part of the inheritance shall fall to any female, but the whole to the male sex.

By salic lands, or inheritances, were anciently denoted, among us, all lands, by whatever tenure held, whether noble or base, from the succession whereto women were excluded by the salic law; for they were by it admitted to inherit nothing but moveables and purchases wherever there were any males.

**SALICARIA**, in botany, Tournefort's name for the lythrum. See the article **LYTHRUM**.

**SALICORNIA**, in botany, a genus of plants, whose flower hath no corolla; the cup is four-cornered, truncated, ventricose, and persistent, and contains but one filament, topped with two oblong antheræ: there is no pericarpium, but the cup becomes more ventricose, and contains a single seed.

A decoction of the leaves of this plant is very opening, provokes urine and the menses, accelerates the birth and secundines, purges watry humours, whence it is of service in a dropsy. Its ashes are used in making soap and glass; and being infused in water, cure the itch and all cutaneous diseases, the part affected being washed therewith.

**SALIVA**, spittle, a thin pellucid humour, separated from the arterial blood, by the glands about the mouth and fauces, and conveyed by proper salival ducts, into the mouth, for several uses.

It consists of a great deal of water or phlegm, and a volatile salt, and some add a sulphureous spirit; and is void both of taste and smell.

Its uses are very great; it moistens the throat, preserves it from the injuries of the air, and facilitates speech. Being mixed with aliment, it renders swallowing easy, and assists digestion by its aqueous, saline, and oily parts. Some imagine it to do the office of a menstruum, by mixing the oily and aqueous parts of the food more intimately, dissolving the saline parts, and procuring a fermentation in the stomach; but Dr. Drake is of opinion, that was the saliva acrimonious enough for this purpose, it must greatly offend the stomach, especially considering the quantities of it that many swallow, even upon an empty stomach. In hungry persons, says Boerhaave, it is fluid, acrid, and copiously discharged; and in those who have fasted long, it is highly acrid, penetrating, and resolvent. In farinaceous and succulent vegetables, it not only produces a fermentation, but also augments one already begun. It is swallowed not only by brutes, but by human creatures, in a sound state, even when asleep. Too copious an evacuation of it, made voluntarily, produces loss of appetite, bad digestion, and an atrophy. By manducation, therefore, the saliva is expressed and accurately mixed with the attenuated food; which contributes, first, to the assimilation of the aliments to the nature of the body to be nourished; secondly, to the due mixture of the oleous to the aqueous parts; thirdly, to the solution of the saline parts; fourthly, to fermentation; fifthly, to a change of the taste and smell of the aliments; sixthly, to an augmentation of the intestine motion; seventhly, to a momentaneous relief from hunger; and, eighthly, an application of the sapid parts, though insipid itself. See the articles **CHYLIFICATION**, **MANDUCATION**, **DIGESTION**, &c.

**SALIVAL**, an epithet applied to the glands and ducts which supply and secrete the saliva. See **GLAND**, **DUCT**, and the preceding article.

**SALIVATION**, in medicine, a promoting of the flux of saliva, by means of medicines, mostly by mercury. The chief use of salivation is in diseases belonging to the glands, and the membrana adiposa, and principally in the cure of the venereal disease, though it is sometimes also used in epidemic diseases, cutaneous diseases, &c. whose crises tend that way. See the articles **POX**, &c.

A salivation is excited according to Boerhaave, 1. By washing the mouth with certain liquors. 2. By the flow and protracted mastication of some viscid matter, such as mastich, wax, and myrrh, especially if acrid substances are mixed with these, such as pellitory of Spain, pyrethrum, ginger, and pepper. 3. By drawing into the mouth acrid and irritating vapours, such as those of tobacco, sage, rosemary, marjoram, thyme, and mother of thyme. 4. A salivation is excellently excited by the action of such medicines as produce a gentle but long continued nausea, such as antimony, neither entirely  
fixt,

fixt nor totally emetic, taken with a small quantity of common vitriol. 5. By such substances as totally dissolve all the parts of the blood, convert it into lymph, and render it fit for a discharge by way of saliva; such as crude quicksilver, cinnabar, a solution of quicksilver in aqua fortis, white precipitate, red precipitate, turbith mineral, and sublimate mercury dissolved: the action of those medicines is promoted by warm fomentations applied to the head, neck, and face. An excessive salivation is lessened or stopped, 1. By a large and continual use of mild and tepid drinks, such as decoctions of mallows and liquorice in milk and water. 2. By allaying the impetus of the humours, by means of mild, oleous, and anodyne emulsions, with a proper addition of diacodium or opium. And, 3. By making a revulsion of the humours to other parts, especially that by stool. But great caution is necessary, lest the impetus of the moved matter, which in this case is always acrid, should rush to other parts, and produce a greater danger.

The regular, safest, and most commodious method of salivation is by mercurius dulcis six times sublimed, given inwardly in the milder pox, &c. or by mercurial unction, when the disease is got into the bones. According to Turner, fifteen grains of mercurius dulcis may be given in a morning, and a like dose at night, with electuary of scordium. After three, four or five days, with this management, the fauces are observed to inflame, the inside of the cheeks to tumify, the tongue to look white and foul, the gums to stand out, the breath to stink, and the whole inside of the mouth to appear shining and lie in furrows as if parboiled. The patient now refuses nourishment, while all parts of his chaps are so swelled and sore that he cannot chew any solid food, but is forced to take liquids and the softer aliments. They are now frequently sick, and throw up a thin phlegm. The inside of the mouth thus beginning to be whealed, will soon be ulcerated, especially about the salival glands, which empty themselves thereinto. Now it may be proper to desist a day or two, to observe the increase of the ulcers, what sloughs are like to be raised, and what their depth and dimensions are like to prove, from which a near conjecture may be made of the duration as well as quantity of the spitting now begun, and the consistence of the drilling lymph. The salivation thus begun, the patient is to be sometimes refreshed by a little mulled wine. Let his diet be small chicken-broth, water-gruel and panada; his drink small sack-whey, or posset drink, and a draught of good small beer, with a toast, between whiles; and in case of gripes or a looseness, the white decoction.

Thus, after some days respite, if the patient is hearty, his chaps but little swelled on the outside, and as little sore within, the ulcers not increasing,

and the flux inconsiderable, you may give one scruple of mercurius dulcis in electuary of scordium at going to rest, repeating it two or three days following, as you find occasion; or you may vomit him with eight or ten grains of turpeth mineral, in conserve of roses: but if the salivation cannot be raised to any quantity, you must forbear, and purge it off, and give calomel once or twice a week, and purge it off the next day, or two days after. When the spitting goes well forward, it may be left to take its course, till it declines of itself, which, in proportion to the ulcers and thickness of the sloughs about the mouth, may happen at the end of twenty-one days or a month from its first rising; that is, from the time of spitting a pint and a half a day, till it come to three pints or even five pints in twenty-four hours, then it gradually goes off again.

In the more stubborn and rebellious pox, &c. attended with grievous symptoms, such as rotten bones, &c. and the patient has been used to mercurials, or salivated before, then the cure must be attempted with salivation by unction. To this end mix an ounce of quicksilver with three ounces of axungia, of which an eight part is to be used night and morning, letting the patient rub it with his own hands gently by the fire, beginning with his ancles, up to his shins and knees, all round his joints, and so to his thighs, which are presently after to be covered with yarn stockings and flannel-drawers; then let him use the remainder of his eight part above his elbows and shoulders, wiping his hands clean about the glands of his arm-pits, or those of his groin: his body during the unction, should be screened from the cold with a blanket hung behind him, and then be wrapped up in warm flannel, that is a flannel-shirt, waistcoat, drawers, cap and muffler. And the same is requisite in the former way, to defend the patient from the cold air. The weak need only to anoint once a day; but those that are strong, may take a fourth part of the ointment, and rub it in at once every night; after which let him get between flannel-sheets or blankets, disposing him to a gentle breathing sweat with a draught of warm posset, mace ale, or if very feeble, with a cup of mulled wine. If, when the ointment is divided into four parts, after the third unction, the patient begins to complain of his chaps, you may stay a day or two before you proceed farther; the same when gripes or bloody stools approach. On the other hand, if an ounce or an ounce and an half of quicksilver will not do, give the turpeth, as before directed: and if the spitting declines too suddenly, give a scruple of calomel every day, for two or three times, as you see occasion. When the salivation is going off, the patient may be purged with two or three ounces of the common infusion of senna, and one ounce of the syrup of buckthorn.

For the several diseases that supervene a salivation, see each of them separately treated of, under their several heads.

To prevent the jaws from being locked up, it is necessary to use a bit of stick, covered with a soft rag, to be held between his backward teeth; and if there should happen an adhesion of the inside of the cheek to the gum, the same is to be carefully divided. If, during the salivation, a blood-vessel burst open, it is to be closed up with a little pellet, covered with powder of alum, or vitriol, and dipped in the tinctura stiptica: if it happens from the separation of sloughs from the sides of the cheeks, a little oxycrate held in the mouth will do the business. If the patient has been without a stool for some time, give him an emollient clyster of warm milk, sugar, and oil; and if the fauces should suddenly tumify, so as to endanger a suffocation, the most certain relief is to bring the humours downwards by sharp clysters and cathartics.

The patient should be prepared for a salivation by a lenitive purge or two; and if plethoric, he should bleed: likewise, bathing in warm water, for some hot, lean emaciated people, has been found of service. Women should be laid down just after their menstrual flux is over. Temperate weather is the most suitable.

**SALIX**, the willow, in botany. See the article **WILLOW**.

**SALLET**, or **SALLAD**, a dish of eatable herbs, ordinarily accompanying roast meat, composed chiefly of crude fresh herbage, seasoned with salt, oil, and vinegar; some add mustard, hard eggs, and sugar; others pepper; and others spices, with orange-peel, saffron, &c.

The principal sallet-herbs, and those which ordinarily make the basis of our sallets, are lettuce, celery, endive, cresses, radish, and rape; to which are sometimes added purslane, spinach, sorrel, tarragon, burnet, corn-sallet, and chervil.

**SALLOW**, the same with willow. See the article **WILLOW**.

**SALLY**, in architecture, is what we more commonly call projecture. See the article **PROJECTURE**.

**SALLY**, in the military art, the issuing out of the besieged, from their town or fort, and falling upon the besiegers in their works, in order to cut them off, nail their cannon, hinder the progress of their approaches, destroy their works, &c.

**SALMON**, *Salmo*, in ichthyology, a genus of the malacopterygious class of fishes, having large, sharp, and strong teeth in both jaws, and on the palate, tongue, and fauces; the back-fin is placed nearer the head of the fish than the ventral ones; the body is, in most of the species, variegated with spots; and the branchiostege membrane contains ten, eleven, or twelve bones.

The several species of this fish are the common salmon, the trout, the red charr, &c. See the articles **TROUT**, &c.

**SALON**, or **SALOON**, in architecture, a very lofty spacious hall, vaulted at top, and sometimes comprehending two stories or ranges of windows. The salon is a grand room in the middle of a building, or at the head of a gallery, &c.

Its faces or sides ought all to have a symmetry with each other; and, as it usually takes up the height of two stories, its ceiling, as Daviller observes, should be with a moderate sweep.

Salons are frequently built square, and sometimes octagonal.

**SALOP**, in the materia medica, &c. See the article **SALEP**.

**SALSIFY**, in botany, a species of tragopogon, cultivated in gardens, being frequently used for several culinary purposes.

It is propagated from seeds, which should be sown in April, upon an open spot of ground, in rows, about nine or ten inches asunder: when the plants are come up, they should be thinned out to about six inches asunder, in the rows; and if the soil be rich, and not too dry, the roots will be large enough for use by winter. Some cultivate it for the stalks, which are cut in the spring, when they are four or five inches high, and dressed and eaten as asparagus.

**SALSOLA**, in botany, the name by which Linnæus calls the kali of other botanists. See the article **KALI**.

**SALT**, *Sal*, in natural history, the name of a series or subdivision of fossils, naturally and essentially simple, not inflammable, and soluble in water.

Dr. Shaw defines salt to be a substance that readily dissolves in water, tastes sharp and pungent upon the tongue, and has a great disposition to unite with earth, so as to appear in a solid form; as in common salt, allum, &c.

Salts then are fossile bodies, friable, pellucid, not inflammable, but fusible by fire, and congealing again in the cold; soluble in water, so as to disappear in it, naturally concreting into regularly figured crystals, and impressing a sensation of acrimony on the tongue. These are the characters and qualities common to all salts, and to no other bodies: and these they always manifest when pure and freed from heterogeneous substances; but in the state in which they are naturally found in the earth, though they have that in their taste alone which may sufficiently distinguish them, yet they do not exhibit all their characters: some of them being found solid and pure, either within the earth or on its surface, but commonly without their proper form; others embodied in earths and stones, as the particles or metals in their ores; and others in a fluid state suspended in waters.

Of the fossils of this class, nature therefore affords us three distinct orders, and under those they are distinguishable into five genera. The salts of the first order are those found native and pure, either in the earth or without its surface, and exhibiting all other natural characters, though often without their proper form. Of the second, are those found not native, but in form of ores, never pure, but distinguishable by their taste, and immersed in and blended with the constituent matter of earths and stones in extremely small particles. And of the third are those naturally found suspended in waters, and in a fluid form, but ready to assume their proper figures on the evaporation of a part of that water.

Of the first of these orders are the common alimentary salt or muria, and the natrum or nitre of the antients; of the second are alum and nitre; and of the third are borax and halscrptium, an alkaline salt hid in the chalybeate waters.

Alimentary salt, or muria, is found under a great variety of forms in its different states; but is immediately distinguished by applying it to the tongue, and always assumes a cubic, pyramidal, or paralleloiped figure after solution, and a regular crystallization. It is sustained in vast quantities in a liquid form among sea-water, and that of salt-springs; but is also found solid in the bowels of the earth in vast masses, which are either of a fine pellucid structure, and called sal-gem; or various, debased, and striated, resembling the fibrose talcs, and is the sal ammoniac of the ancients. See the articles GEM and AMMONIAC.

But in which ever of these forms this salt is found, it affords the same crystals on evaporation: these, according to the degree of heat used in the evaporation, are either pyramidal, cubic, or paralleloiped. All these salts are soluble in water, but they require different quantities of it to dissolve them, and this makes one of their criterions. This salt requires thrice and one seventh part its own quantity of water, to make a perfect solution.

The sea-water, in different parts of the world, is very differently sated with it, some parts containing twice as much as others. But that of the salt springs is always much more salted with it, than the strongest of the sea-water: in some places it is found loaded with nearly as much as it could be made to contain, some springs yielding a brine that affords a quarter of a pound of salt, from the pound weight of this liquor, and many of them being so strongly impregnated, that the workmen are obliged to let them down or lower them, by mixing them with a large quantity of sea or common water, before they are fit to be boiled for the salt: the common run of sea-water does not hold so much as one fourth part of this quantity, some not one eighth of it.

The salt produced from the sea-water of all parts of the world, and from the brine of all the springs in the world, is absolutely the same; but differs in strength, and some other qualities, according to the operation by which it is made. In general, the quicker the liquor is evaporated, the weaker is the salt; the more time is employed in the process, the stronger. This is not wonderful, when we consider, that, over a gentle heat, water alone, or almost alone, evaporates from the liquor, but, over a more violent fire, a part of the strength or acid of the salt is raised with it.

It is upon this principle, and owing to this cause, that we find the salt of our salt springs, which is usually sold us under the name of basket-salt, the weakest of all. It is not that there is any difference in the waters from which these several kinds of salt are produced, that they appear to us in different degrees of strength, but that the people who work the brine pits, make the salt with less expence of the workman's time; that the sea-salt is formed over somewhat slower fires, and that the bay-salt is made only by the sun's heat, where the process is very long, and the heat very moderate, and the salt is found strong in proportion. This is so indisputable a truth, that once every week, a very strong salt, little inferior to bay-salt in that quality, is made at the brine-pit works, where the common run of the salt is the weakest in the world. The liquor is the same in this case, but the workmen, who do not work on Sundays, leave a pan full to evaporate slowly over the fire, which they prepare on the Saturday night, and the moderate heat and length of time under which this weekly parcel of salt is made, render it very different from the common salt of the works, both in form and qualities; it is found to be made up of large and hard grains, instead of the small and soft ones of the common kind, and is vastly superior to it in strength.

This circumstance, overlooked by the workmen, and even by their masters too, for many years, gave the hint to Mr. Lownds, and afterwards to the very ingenious Dr. Browning, author of an excellent treatise on this subject, to propose to the government a method of making a strong salt fit for all the purposes for which we buy it of our neighbours, only by a new, that is, by a slower way of working our own brines. The latter of these gentlemen has proved, incontestibly, that we may, if we will encourage proper manufactures, have common salt of every kind made at home, equal in strength, and equally fit for all purposes, with the salt of any part of the world.

Physicians are of opinion, that sea-salt has the same effects in the human body that it has out of it, in checking fermentation, and preventing putrefaction; they therefore esteem it of good use mixed with the generality of our foods in the stomach; they

they are of opinion also, that it carries its effect into the blood, and has the qualities of a moderate dryer, detergent and attenuant, added to those of a stimulant, which common reason declares it to be. Hence may be deduced all the virtues attributed to salt, as an aperient, stomachic, or warming medicine, and a provocative to venery; but in what degree it possesses all these qualities, we are, by its universal use in foods, prevented from being able to determine. Van Helmont recommends it as a good preservative against the stone and gravel: he has been severely censured for this by others, who are of opinion, that all salted foods, such as salt beef, and the like, are very bad in those cases: but both parties may be in the right; for there is a great deal of difference between common salt eaten with the fresh juices of our food, and the brine and pickle into which it runs in the time of its being left upon the meat preserved by it. Salt is very properly put into the mouths of people in apoplectic fits, as it not only irritates but attenuates the juices there, and promotes a discharge of them; and in a palsy which affects the tongue, a sage leaf, bruised and covered with salt, has been a famous remedy among the good women, and not without reason.

Mixed with bran, and heated in a canvas bag, it is recommended to be applied externally to the head in head-achs, arising from a moist cause, and in defluxions: and we find the old physicians very strenuously recommending a cataplasm made of the same ingredients for pains.

*Methods of making alimentary SALT* are these.

1. By the evaporation of the sun's rays: this is the most easy and simple method of all, when the waters of ponds and lakes, whether natural or artificial, impregnated with salt, being wholly exhaled by the force of the sun and air, the salt is left concreted into a hard crust at the bottom of the lake, and is what commonly goes by the name of bay-salt; the crystals of which differ in size, according to the different degrees of heat, and the time it lies in the pits. All bay-salt has some mud, slime, or the like, in the making, and some kinds are mixed with the bittern salt, or what is called Epfom salt; they are all more white while dry, and more pelucid when moist, and they differ in colour, according to the earth which makes the bottom of the pits. Thus some of the French bay-salt is grey, some reddish, and some white, according as a blue clay has lined the pits, or a red, or white one. Some kinds have also an agreeable smell in large heaps; such are the Portugal, and the Hampshire bay-salts; and this seems owing to the sea-water they were made from, having a bituminous matter in it. It differs also greatly in taste, according to the various foreign mixtures it contains; and it will often alter in taste, and other qualities, by long keeping: for, in general, it is much fitter for use, after it has

been kept some time in a dry place, than when it is first made.

2. By boiling or coction; the most convenient works for which process are constructed in the following manner: the saltern or boiling-house, is erected near the sea shore, and is furnished with a furnace and one or two large pans, which are commonly made of iron plates, joined together with nails, and the joints filled with a strong cement; and the bottoms of the pans are prevented from bending down, by being supported by strong iron-bars.

The salt-pan being filled with sea-water, a strong fire of pit-coal is lighted in the furnace, and then, for a pan which contains about fourteen hundred gallons, the salt-boiler takes the whites of three eggs, and incorporates them all with two or three gallons of sea-water, which he pours into the salt-pan, while the water contained therein is only lukewarm, and mixes this with the rest by stirring it about with a rake. In many places they use, instead of eggs, the blood of sheep or oxen to clarify the sea-water; and in Scotland they do not give themselves the trouble to clarify it at all. As the water heats, there arises a black frothy scum upon it, which is to be taken off with wooden skimmers. After this the water appears perfectly clear; and by boiling it briskly about four hours, a pan loaded in the common way, that is about fifteen inches deep, will begin to form crystals upon its surface. The pan is then filled up a second time with fresh sea-water; and about the time when it is half filled, the scratch-pans are taken out and emptied of a white powder, seeming a kind of calcarious earth, which separates itself from the sea-water, during its boiling, before the salt begins to shoot. When these have been emptied, they are again put into their places, where they are afterwards filled again. This powder being violently agitated by the boiling liquor, does not subside till it comes to the corners of the pan, where the motion of the mass is smaller, and it there falls into these pans placed on purpose to receive it.

The second filling of the pan is boiled down after clarifying in the same manner as the first, and so a third and a fourth; but in the evaporation of the fourth, when the crystals begin to form themselves, they slacken the fire, and only keep the liquor simmering. In this heat they keep it all the while the salt is granulating, which is nine or ten hours. The granules or crystals all fall to the bottom of the pan; and when the water is almost all evaporated, and the salt lies nearly dry at the bottom, they rake it altogether into a long heap on one side of the pan, where it lies a while to drain from the brine, and then is put into barrows and carried to the store-house, and delivered into the custody of his majesty's officers. In this manner the whole process

is performed in twenty-four hours, the salt being commonly drawn out every morning. This is the method in most of our salt-works, but in some they fill the pan seven times before they boil up the salt, and so take it out but once in two days, or five times in a fortnight. In the common way of four boilings, a pan of the usual size, containing one thousand three hundred gallons, they draw from fifteen to twenty bushels of salt every day, each bushel weighing fifty-six pounds.

When the salt is carried into the store-house, it is put into drabs, which are partitions, like stalls for horses, lined at three sides and at the bottom with boards, and having a sliding board on the fore-side to draw up on occasion. The bottoms are made shelving, being highest at the back and gradually inclining forward; by this means, the brine remaining among the salt, easily separates and runs from it, and the salt, in three or four days, becomes sufficiently dry; in some places they use cribs and barrows, which are long and conic wicker baskets, for this purpose; and in some places, wooden troughs with holes at the bottom. The saline liquor, which remains from the making of salt, is what is called bitter. See the article BITTERN.

Much in the same manner is the salt obtained from the brine of salt springs, pits, &c. White salt is prepared from sea-water, or any other kind of salt-water, first heightened into a strong brine by the heat of the sun and the operation of the air. It may also be prepared from a strong brine, or lixivium, drawn from earths, stones, or sands, strongly impregnated with common salt.

Refined rock-salt is that obtained by dissolving fossile or rock salt in salt of fresh water, and afterwards boiling the solution. And, lastly, salt upon salt is made from bay-salt dissolved in sea-water, or other water, and boiled to a white-salt.

SALT, in chemistry, makes one of the leading and most active principles, or elements, procurable from mixed bodies.

There are three kinds thus obtained, two whereof are volatile, and the third fixed.

The volatile, are acrid and urinous salts; the fixed, lixivious, or those drawn from ashes: the urinous and lixivious salts are also called alkalies, or alkalis salts; the former being volatile, and the latter fixed.

SALT-PETRE, the same with nitre. See the article NITRE.

SALT-WORT, *Salicornia*, in botany. See the article SALICORNIA.

SALTIER, in heraldry, an ordinary in form of a St. Andrew's cross; which may be said to be composed of a bend dexter and sinister, crossing each other in the center of the escutcheon.

SALVAGE-MONEY, a reward allowed by the civil and statute law, for the saving of ships or

goods from the danger of the seas, pirates, or enemies.

Where any ship is in danger of being stranded, or driven on shore, justices of the peace are to command the constables to assemble as many persons as are necessary to preserve it; and on its being preserved by their means, the persons assisting therein, shall, in thirty days after, be paid a reasonable reward for the salvage; otherwise, the ship or goods shall remain in the custody of the officers of the customs, as a security for the same.

SALVATELLA, in anatomy, a branch of the axillary vein, which runs over the back of the hand towards the little-finger.

SALVIA, sage, in botany, &c. See the article SAGE.

SALVINIA, or MARSILEA, in botany. See the article MARSILEA.

SALUTATION, the act of saluting, greeting, or paying respect or reverence to any one.

There is a great variety in the forms of salutation. The Orientals salute by uncovering their feet, laying their hands on their breasts, &c. In England, we salute by uncovering the head, bending the body, &c. The pope makes no reverence to any mortal, except the emperor, to whom he stoops a very little, when he permits him to kiss his lips.

SAMARITANS, an ancient sect among the Jews, still subsisting in some parts of the Levant, under the same name.

Its origin was in the time of Rehoboam, under whose reign the people of Israel were divided into two distinct kingdoms, that of Judah and that of Israel; when the capital of the latter being Samaria, the Israelites obtained the name of Samaritans.

They were anciently guilty of idolatry, and the Rabbins pretend, that they worshipped the figure of a dove, on mount Gerizim; but the present Samaritans, who are but few in number, are far from being idolaters.

They celebrate the passover every year, on the fourteenth day of the first month, on mount Gerizim, and begin that feast with the sacrifice appointed for that purpose in Exodus: they keep the sabbath with all the rigour with which it is enjoined in the book of Exodus, none among them stirring out of doors but to the synagogue: they sacrifice no where but on mount Gerizim: they observe the feasts of expiation, tabernacles, harvest, &c. and never defer circumcision beyond the eighth day: they never marry their nieces as the Jews do: have but one wife; and, in fine, do nothing but what is commanded in the law.

SAMARITAN MEDALS, some ancient medals in the cabinets of our antiquaries, the inscriptions and legends of which are in Hebrew; but the character different from the Hebrew of our Bibles, which is the square Hebrew, or Chaldee; from this character,

ter, and not from their being struck by the Samaritans, they are denominated Samaritan.

**SAMBUCUS**, the elder, in botany, a genus of umbelliferous plants, the flower of which is monopetalous, of a concave rotated form, cut into five obtuse segments, which are reflexed at their edges: the fruit is a roundish unilocular berry, containing three seeds, convex on one side and angulated on the other.

The common elder has a long woody whitish root, and the branches are large, round, and full of a white pith; they are green at first, but afterwards turn to a grey colour: the trunk is covered with a rough ash-coloured bark, full of cracks; under which is the inner bark, of a green colour: the leaves are dentated on their edges, and grow five or six of them on a mid-rib, which is terminated by an odd one: the flowers come out in May or June from the tops of the branches, in large umbels, and are of a white colour; these are succeeded by green berries, which in autumn turn black and very full of juice.

The elder will grow in almost any soil and situation; it may be propagated by seeds, but the most common method of increasing it is by cuttings or truncheons stuck in the ground.

The wood of elder is used as a substitute for box in several businesses, and particularly for making workmen's rules, of the cheap sort.

All the parts of this tree are used in medicine, and are generally known to have a purging and aperient quality; the inner bark is esteemed good in dropfies, and is accounted a good antiscorbutic; the leaves are outwardly applied in the piles and inflammations; the flowers are used inwardly to expel wind, and outwardly, in erysipelatous inflammations, and arthritic swellings; the berries are esteemed cordial, and useful in hystERIC disorders, and are frequently put into gargarisms for sore mouths and throats; the wine made from these berries, is so well known as to need no description.

**SAMBUCUS**, is also an ancient musical instrument of the wind kind, resembling a flute; probably thus called, because made of elder.

**SAMIAN EARTH**, in the materia medica, the name of two species of marl used in medicine, viz.

1. The white kind, called by the ancients, collyrium samium; being astringent, and therefore good in diarrhoeas, dysenteries, and hæmorrhages; they also used it externally in inflammations of all kinds.
2. The brownish-white kind, called after samius, by Dioscorides: this also stands recommended as an astringent. See the article **MARL**.

**SAMOLUS**, in botany, an annual plant, growing wild in watery places; the stalks rise to about a foot in height, and are slender, round, and stiff, with the leaves placed alternately on them, without pedicles; the flowers grow on the tops of the stalks

and branches, and consist each of a monopetalous saucer-shaped corolla, with the limb divided into five plane obtuse segments: the fruit is an ovate unilocular capsule, opening half way, with five valves, and containing a great many ovate small seeds.

This plant is reckoned to be vulnerary, aperient, and cleansing.

**SAMOSATENIANS**, in church history, the same with Paulianites. See the article **PAULIANITES**.

**SAMPHIRE**, *Crethmum*, in botany. See the article **CRETHMUM**.

**SAMPSEANS**, in church history, an ancient sect, who were properly neither Jews, Christians, nor Gentiles, though they took their name from the Hebrew word *Semes*, sun; as though they worshipped that planet.

They acknowledged only one God; washed themselves often; and in almost every thing attached themselves to the religion of the Jews: many among them abstained wholly from eating of flesh.

Scaliger will have the Sampseans to be the same with the Esseni; and indeed the Sampseans, Esseni, Elcesaites, and Massalians, appear to be no more than so many different names for the same sect.

**SAMYDA**, in botany, a genus of plants, whose flower hath no corolla; the calyx is campanulated, coloured, spreading, and persistent, including a nectarium formed of five scales: the fruit is a roundish unilocular capsule, filled with a pulp, and contains a number of baccated seeds.

**SANAMUNDA**, in botany, the same with the empetrum, or heath spurge. See the article **EMPETRUM**.

**SANCTIFICATION**, the act of sanctifying, or rendering a thing holy.

The reformed divines define sanctification to be an act of God's grace, by which a person's desires and affections are alienated from the world, and by which he is made to die to sin, and to live to righteousness; or, in other words, to feel an abhorrence of all vice, and a love of virtue and religion.

**SANCTION**, the authority given to a judicial act, by which it becomes legal and authentic.

**SANCTUARY**, among the Jews, also called sanctum sanctorum, or holy of holies, was the holiest and most retired part of the temple of Jerusalem, in which the ark of the covenant was preserved, and into which none but the high-priest was allowed to enter, and that only once a year, to intercede for the people.

Some distinguish the sanctuary from the sanctum sanctorum, and maintain that the whole temple was the sanctuary.

**SANCTUARY**, in our ancient customs, is the same with asylum. See the article **ASYLUM**.

SANC-

**SANCTUARY**, in the Romish church, is also used for that part of the church in which the altar is placed, inc compassed with a rail or ballustrade.

**SAND**, *Arena*, in natural history, a genus of fossils, the characters of which are, that they are found in minute concretions; forming together a kind of powder, the genuine particles of which are all of a tendency to one determinate shape, and appear regular, though more or less complete concretions; not to be dissolved or disunited by water, or formed into a coherent mass by means of it, but retaining their figure in it; transparent, vitrifiable by extreme heat, and not dissoluble in, nor effervescing with, acids.

Sands are subject to be variously blended both with homogeneous and heterogeneous substances, as that of talcs, &c. and hence, as well as from their various colours, are subdivided into, 1. White sands, whether pure or mixed with other arenaceous or heterogeneous particles; of all which there are several species, differing no less in the fineness of their particles, than in the different degrees of colour, from a bright and shining white, to a brownish, yellowish, greenish, &c. white. 2. The red and reddish sands, both pure and impure. 3. The yellow sands, whether pure or mixed, are also very numerous. 4. The brown sands, distinguished in the same manner. 5. The black sands, whereof there are only two species, viz. a fine, shining, greyish-black sand, and another of a fine, shining, reddish-black colour. 6. The green kind, of which there is only one known species, viz. a coarse, variegated, dusky-green sand, common in Virginia.

Sand is of great use in the glass manufacture; the white writing-sand being employed for making the white glass, and a coarse greenish-looking sand for the green glass.

In agriculture, the office of sand seems to be to make unctuous earths fertile, and fit to support vegetables, &c. for earth alone, we find, is liable to coalesce, and gather into a hard coherent mass, as appears in clay; and being thus embodied, and as it were glued together, is no way disposed to nourish vegetables: but if such earth be mixed with sand, its pores are thereby kept open, and the earth itself loose, so as thus to give room for the juices to ascend, and for plants to be nourished thereby.

A vegetable planted only in sand, or in a fat glebe, or in earth, receives little growth or increase; but a mixture of both renders the mass fertile. In effect, earth is in some measure made organical by means of sand; pores and spaces, something analogous to vessels, being thereby maintained, by which the juices may be conveyed, prepared, digested, circulated, and at length discharged.

Common sand is a very good addition, by way of manure, to all sorts of clay lands; it warms them, and makes them more open and loose.

The best sand for the farmer's use, is that which is washed by rains from roads or hills, or that which is taken from the beds of rivers; the common sand that is dug in pits never answers nearly so well. However, if mixed with dung, it is much better than laid on alone: and a very fine manure is made by covering the bottom of sheep-folds with several loads of sand every week, which are to be taken away, and laid on cold stiff lands, impregnated as they are with the dung and urine of the sheep.

Beside clay land, there is another sort of ground very improveable by sand; this is that sort of black foggy land on which bushes and sedge grow naturally, and which they cut into turf in some places.

Six hundred load of sand being laid upon an acre of this land, according to the Cheshire measure, which is near double the statute acre, meliorate it so much, that without plowing, it will yield good crops of oats or tares, though before it would have produced scarce any thing. If this crop is taken off, the land well dunged, and laid down for grass, it will yield a large crop of sweet hay.

Once sanding this land will improve it for a vast number of years, and it will yield two crops of hay in the year, if there be weather to make it in. Some land in Cheshire has been, by this means, rendered of twelve times its former value to the owner.

The bogs of Ireland, when drained, have been rendered very fruitful land, by mixing sand in this manner among the earth, of which they consist. Add to this, that in all these boggy lands, the burning them, or firing their own turf upon them, is also a great advantage.

The common peat or turf ashes, mixed with the sand for these purposes, add greatly to its virtue.

Sea-sand, which is thrown up in creeks and other places, is by much the richest of all sand for manuring the earth; partly its saltness, and partly the fat and unctuous filth that is mixed among it, give it this great virtue. In the western parts of England, that lie upon the sea-coast, they make very great advantages of it. The fragments of sea-shells, also, which are always in great abundance in this sand, add to its virtues; and it is always the more esteemed by the farmers, the more of these fragments there are among it.

That sea sand is accounted the best, which is of a reddish colour: the next in value to this, is the bluish; and the white is the worst of all. Sea sand is best when taken up from under the water, or from sand-banks which are covered by every tide. The small-grained sand is most sudden in its operation, and is therefore best for the tenant, who is only to take three or four crops; but the coarse, or large-grained sand, is much better for the landlord, as the good it does, lasts for many years. When the land has been well manured with the large sand,

they take four crops of corn from it, and then lay it down for pasture, for six or seven years before they plough it again.

The grass is so good, that they commonly mow it for hay the first year; it always abounds very much with the white-flowered clover. If the grass grows but short, it is the farmer's interest to feed his cattle upon it, and it will turn to as good account this way, being very sweet and rich, and making the cattle fat, and the cows yield a very large quantity of milk.

**SAND-BAGS**, in the art of war, are bags filled with sand or earth, holding each about a cubic foot: their use is to raise parapets in haste, or to repair what is beaten down.

**SAND-BOX-TREE**, *Hura*, in botany. See the article **HURA**.

**SAND-FLOOD**, a terrible mischief, incident to the lands of Suffolk, and some other parts of England; which are frequently covered with vast quantities of sand, rolling in upon them like a deluge of water, from sandy hills in their neighbourhood.

The best way of stopping its progress, is by hedges of furze, planted one over another as they become level.

**SAND-LANDS**, or **SANDY-LANDS**, in agriculture, are made up of sand of different colours and qualities; as white, blackish, reddish, or yellowish; and in the size of their particles, some being milder or harsher, and others very light, seeming mere dust. The grey, black, and ash-coloured sands, are the worst of all, and are generally found on heaths and commons.

The most suitable plants for arable lands of this kind, are white oats, rye, black wheat, and turneps: the natural produce in weeds, is quick-grass, sorrel, broom, furze, fern, and heath.

The best manure for them, is either marl, or such clay as will break with the frosts. Cow-dung is also said to be good for such lands; and many use with success, chalk, mud, and the half-rotten straw of dunghills.

**SANDAL**, in antiquity, a rich kind of slipper, worn on the feet by the Greek and Roman ladies, made of gold, silk, or other precious stuff, consisting of a sole, with a hollow at one extreme to embrace the ankle, but leaving the upper part of the foot bare.

It is also the name of a shoe or slipper worn by the pope, and other Romish prelates, when they officiate.

**SANDARACH**, in natural history, a very beautiful native fossil, though too often confounded with the common facitious red arsenic, and with the red matter formed by melting the common yellow orpiment.

It is a pure substance, of a very even and regular structure, is throughout of that colour which our dyers term an orange-scarlet, and is considerably

transparent, even in the thickest pieces. But though, with respect to colour, it has the advantage of cinabar while in the mass, it is vastly inferior to it when both are reduced to powders. It is moderately hard, and remarkably heavy, and when exposed to a moderate heat, melts and flows like oil: if set on fire, burns very briskly.

It is found in Saxony and Bohemia, in the copper and silver mines, and is sold to the painters, who find it a very fine and valuable red: but its virtues or qualities in medicine, are no more ascertained at this time, than those of the yellow orpiment.

**Gum-SANDARACH**, is a dry and hard resin, usually met with in loose granules, of the bigness of a pea, a horse-bean, or larger; of a pale whitish yellow, transparent, and of a resinous smell, brittle, very inflammable, of an acrid and aromatic taste, and diffusing a very pleasant smell when burning. It is produced from a species of the juniper, and the *cedrus baccifera*. See **JUNIPER**.

It flows only from these trees in hot countries; but the natives promote its discharge by making incisions in the bark.

What is obtained from the cedar is more fragrant, especially when burnt; but it is seldom to be met with separate in the shops, both being mixed together under the common name of sandarach.

Sandarach is good in diarrhoeas, and in hæmorrhages; where its dose is from ten grains to half a dram: it is also sometimes prescribed in gonorrhæas, and the fluor albus; but at present it is much disused in medicine. It is, however, much used by our writing-masters, who make a powder of it, which they call pounce.

The varnish-makers make a kind of varnish of it by dissolving it in oil of turpentine, or linseed, or in spirit of wine.

**SANDIVER**, a whitish salt, continually cast up from the metal, as it is called, whereof glass is made; and swimming on its surface, is skimmed off. See the article **GLASS**.

**SANDIX**, a kind of minium, or red-lead, made of ceruse; but much inferior to the true minium.

**SANGUIFICATION**, in the animal œconomy, the conversion of chyle into true blood. See the articles **CHYLE**, **CHYLIFICATION**, and **BLOOD**.

Blood is formed from chyle by various and successive degrees. A few hours after meals, the chyle is found conveyed into the blood, though not assimilated. Hence, when after a liberal meal, blood is taken from the vein, besides the serum and the red part, there is a white, sweet, and chylous part found fluctuating in the blood. In a few hours the chyle, conveyed with the blood through the vessels, is separated from the blood by the fabric of the breasts, and affords milk, which is of a different nature both from blood and chyle; for in milk there begins to be formed that tendency to concretion.

tion which is already present in the serum of the blood, for it yields cheese. But this tendency to concretion is never found in the chyle. Hence we may artificially imitate the preparation of chyle in emulsions, but never the nature of milk.

When a sound woman for twelve hours totally abstains from meat and drink, her milk begins to be saline and yellowish. If she abstains still longer, nothing is found in the blood taken from her veins, but what (like the white of an egg) is by means of the fire concreted, which never happens in the chyle.

Hence we may conclude, that the bodies of sound persons are the formers and producers of their own blood, in the same manner as any plant, by its peculiar fabric, prepares its sap from the juices of the fertile earth and the genial influences of the circumambient air.

But in the human body the formation of blood depends principally upon the efficacy of the circulation, by which the vessels act upon their contained fluids. Hence in the most robust persons the blood is reddest, or rather almost black, in consequence of its saturated red colour, and is concreted almost the very moment it is left in a state of rest. And in acute diseases, when the circulation is increased, all the parts are intensely red, and the serum of the blood is converted into a scissile mass. But in weak persons, in whom the efficacy of the circulation is far less, all the parts are pale and languid, whilst the blood is thin and hardly capable of concretion. But when in such persons, with due exercise and proper remedies, the circulation is augmented, the red colour and due cohesion of the blood return.

**SANGUINARIA**, in botany, a genus of plants, whose flower consists of eight oblong, obtuse, spreading petals, with a great number of stamina. The fruit is an oblong ventricose capsule, with two valves pointed at both ends, and contains a great many roundish acuminate seeds.

**SANGUINE**, in general, something abounding with, or resembling blood. See the article **BLOOD**.

Among heralds, the term sanguine is often given to the colour more usually called murrey; being made of red lake tinged with a little Spanish brown; it is chiefly used in the coats of the knights of the Bath, and is represented, in engraving, by hatches like those of purple. See the articles **PURPLE** and **HATCHES**.

**SANGUIS**, blood, in the animal œconomy. See the article **BLOOD**.

**SANGUISORBA**, in botany, a genus of plants, whose flower is monopetalous, rotated, and divided into four deep segments, cohering at their base; the stamina are four filaments the length of the corolla, and topped with small roundish antheræ: the fruit is a small bilocular capsule, which is filled with small seeds.

**SANHEDRIM**, or **SANHEDRIN**, among the Jews, the great council of the nation, consisting of seventy senators, taken partly from among the priests and levites, and partly out of the inferior judges, who formed what was called the lesser sanhedrim. The room they met in, was a rotunda, half of which was built without the temple, and half within. The nasi, or president of the sanhedrim, sat upon a throne, with his deputy on his right hand, his sub-deputy on his left, and the other senators ranged in order on each side.

The authority of this council was very extensive, for they decided such causes as were brought before them by way of appeal from the inferior courts; and the king, the high-priests, and prophets were under the jurisdiction of this tribunal. They had the right of judging in capital cases, and sentence of death might not be pronounced in any other place; for which reason the Jews were forced to quit this hall, when the power of life and death was taken out of their hands, forty years before the destruction of the temple, and three years before the death of Christ.

There were several inferior sanhedrims in Palestine, each of which consisted of twenty-three persons; all these depended on the great sanhedrim of Jerusalem.

**SANICLE**, *Sanicula*, in botany, an umbelliferous plant, which sends forth several broad, roundish leaves, that are smooth, dentated on their edges, and of a fine green shining colour; from among these arises a stalk to the height of a foot, smooth, without knots, and reddish towards the root; on the top are several small flowers, collected into an umbel, each particular one consists of five compressed and bifid petals. The fruit is composed of two seeds, plane on one side, and convex and scabrous on the other. This plant flowers in June, and grows wild in woods and shady places in most parts of England: the leaves have been long noted for their vulnerary virtues both internally and externally, and may be used in the manner of tea.

**SANIES**, in medicine, a ferous putrid matter, issuing from wounds; it differs from pus, which is thicker and whiter.

**SANTALUM**, saunders, in the materia medica, a hard, odoriferous medicinal wood, brought from the East-Indies, of which there are three sorts, viz. the yellow, white, and red: the yellow or citrine saunders, is a beautiful wood, of the colour of lemon-peel, of a smell somewhat like a mixture of musk and roses, and of a somewhat acrid and aromatic taste, with a slight bitterness. The white saunders resembles the yellow, and is of the same fragrant smell and aromatic taste, but in a more remiss degree. Both these sorts should be chosen sound, firm, heavy, and of a good smell when cut; they should also be chosen in the block, and not cut.

cut into chips as they usually are; for in this manner they soon lose much of their virtue. The red Saunders is of a dense and compact texture, remarkably heavy and very hard. It is brought to us in logs of considerable length, the outer part of which is of a dusky colour, and the inner of a blood red; it has but little smell, and it is of an austere taste.

All these sorts are attenuants, and all have an astringency, but the red most of all. They are accounted cordials, and are said to be good in obstructions of the viscera; but they are little used, except as ingredients in some of the compositions of the shops.

Santalum is a plant of the octandria-monogynia class, with a monopetalous campanulated flower, and a berry for its fruit.

SANTOLINA, lavender-cotton, in botany, a genus of plants, whose flower is compound and uniform, with an hemispherical scaly cup; the proper flowers are hermaphrodite, funnel-shaped, and quinquefid at the limb; there is no pericarpium, but the cup contains solitary, oblong, four-cornered seeds, placed on a paleaceous receptacle. The common lavender-cotton has a thick, hard, woody root, from which proceed a shrubby stalk, dividing into many woody branches, which are furnished with slender leaves about an inch long, which are four ways denticulated, they are of a hoary colour, and have a rank strong smell with somewhat of a sweetness, the taste is partly acrid and partly of an aromatic bitter; the branches are terminated by single yellow flowers which appear in July. This plant is cultivated in gardens, and may be propagated by planting slips or cuttings of it in the spring. The leaves, and sometimes the flowers, are used in medicine, and are reputed good to destroy worms.

SAP, in physiology, a juice furnished by the earth, and changed into the plant, consisting of fossil parts, other parts derived from the air and rain, and others from putrified animals, plants, &c. See the article JUICE.

This juice enters the plant in form of a fine and subtle water, which the nearer it is to the root, the more it retains of its proper nature: and the farther from the root, and the more action it has sustained, the nearer it approaches to the nature of the vegetable; consequently, when the juice enters the root, it is earthy, watery, poor, acid, and scarcely oleaginous at all. In the trunk and branches it is farther prepared, though it still continues acid, as we find by tapping a tree in the month of February.

The sap being here carried to the germs or buds, is more concocted; and here having unfolded the leaves, these come to serve as lungs for the circulation and farther preparation of the juice. By such means is the sap still farther altered and digested, as it is farther in the petals or leaves of the flowers, which transmit the juice, now brought to a farther subtilty, to the stamina; these communicate it to

the farina, or dust, in the apices, which is, as it were, the male seed of the plant; where, having undergone a farther maturation, it is shed into the pistil, which performs the office of an uterus or womb; and thus having acquired its last perfection, it gives rise to a new fruit or plant. The sap having thus gone its stage, from the root to the remote branches, and even the flower; and having, in every part of its progress, deposited something both for aliment and defence, what is redundant passes out into the bark, the vessels of which are inosculated with those in which the sap mounts; and through which it descends to the root, and thence to the earth again. And thus a circulation is affected.

SAP, or SAPP, in the art of war, is the digging deep under the earth of the glacis, in order to open a covered passage into the mote. It is only a deep trench, covered at top with boards, hurdles, earth, sand-bags, &c. and is usually begun five or six fathoms from the salient angle of the glacis.

SAPINDUS, in botany, the soapberry-tree; it grows naturally in the West Indian islands, where it rises with a woody stalk twenty or thirty feet high, sending out many branches towards the top, which are furnished with winged leaves composed of three, four, or five pair of lobes of a lanceolated form, drawing to points at both ends, the mid-rib has a membranaceous border running on each side; the flowers are produced in loose spikes at the ends of the branches; they are small, white, and consist each of four oval petals less than the cup, with eight stamina. The fruit is three globose inflated capsules, including in each a round nut. The berries of this tree are used for washing instead of soap, but it is very detrimental to linen if often used, being of an acrid nature.

SAPONARIA, soapwort, in botany, a genus of plants, whose flower consists of five petals, whose unguis are narrow, angulated, and the length of the cup, and the borders are plane, obtuse, and broad; the stamina are ten subulated filaments, terminated with obtuse, oblong, incumbent antheræ. The fruit is a close unilocular capsule the length of the cup, and contains a number of small seeds.

The common soapwort is accounted opening and attenuating, and somewhat sudorific; it is of service in asthmas and all disorders of the breast which require expectoration; outwardly likewise it is recommended for discharging and suppurating tumours.

The leaves agitated with water raise a saponaceous froth, which has nearly the same effect in taking out dirt or spots in cloths as soap, whence the name.

SAPOTA, in botany, a genus of trees, whose flower consists of five roundish cordated petals, which are connected at their base, and five short filaments terminated with arrow-pointed antheræ. The fruit

is oval and succulent, and contains one or two nuts.

**SAPPHIRE**, a pellucid gem, which, in its finest state, is extremely beautiful and valuable, and second only to the diamond in lustre, hardness, and price. Its proper colour is a pure blue; in the finest specimens it is of the deepest azure, and in others varies into paleness, in shades of all degrees between that and a pure crystal brightness and water, without the least tinge of colour, but with a lustre much superior to the crystal. They are distinguished into four sorts, viz. the blue sapphire, the white sapphire, the water sapphire, and the milk sapphire.

The gem known to us by this name is extremely different from the sapphire of the ancients, which was only a semi-opaque stone, of a deep blue, veined with white, and spotted with small gold-coloured spangles, in the form of flars, and was only a more beautiful kind of the lapis lazuli; but our sapphire they have described under the name of beryllus æroides, or the sky-blue beryl.

The finest sapphires in the world are brought from the kingdom of Pegu, in the East-Indies, where some are found perfectly colourless, and others of all the shades of blue: these are all found in the pebble form. We have very fine sapphires also, partly pebble, partly crystal-shaped, from Bishnagar, Conanor, Calicut, and the island of Ceylon: these also are of all the shades of blue. And in Ceylon there are sometimes found a sort of bastard gems, of a mixed nature between the sapphire and ruby. The occidental are from Silesia, Bohemia, and many other parts of Europe; but though these are often very beautiful stones, they are greatly inferior, both in lustre and hardness, to the oriental.

The sapphire is said to have very great virtues as a cordial, sudorific, and alexipharmic; but we have no good testimony of any body's having ever found this by experiment.

For the manner of making counterfeit sapphires, see **GEMS ARTIFICIAL**.

**SAPPHARINE WATER**, in the materia medica, also called blue eye-water, is thus prepared: pour a pint of lime-water, made strong and fresh, into a copper-vessel, add to it a dram of sal armoniac, and throw in some filings or small pieces of copper, and let it stand till it has acquired a beautiful colour.

This is used as an eye-water; as also to deterge old ulcers: and sometimes it is mixed with other things in injections in gonorrhœas.

**SARABAITES**, a sort of monks among the ancient Christians, who did not resort to the wilderness as others did, but lived publicly in cities. Two or three of them usually dwelt together, but they had no rule or government; they however observed very strict fasts; wore loose sleeves, wide stockings, coarse cloaths, frequently sighed, and always bitterly inveighed against the clergy.

**SARABRAND**, a musical composition in triple time, the motions of which are slow and serious.

The sarabrand is said to be originally derived from the Saracens, and is usually danced to the sound of the guitar or castanettes.

**SARCASM**, in rhetoric, a keen bitter expression which has the true point of satire, by which the orator scoffs and insults his enemy: such was that of the Jews to our Saviour, He saved others, himself he cannot save.

**SARCOCELE**, in surgery, a spurious rupture, or hernia, wherein the testicle is considerably tumified or indurated, like a scirrhus, or much enlarged by a fleshy excrescence, which is frequently attended with acute pains, and sometimes ulceration, so as to degenerate at last into a cancerous disposition. See **HERNIA**.

**SARCOCOLLA**, in pharmacy, a gum-resin, which approaches greatly to the nature of the simple gums.

It is brought to us from Persia and Arabia, in small granules, moderately heavy, and of a whitish, brownish, or reddish colour, very friable, of a faintish disagreeable smell, and of an acrid and nauseous taste.

Hoffman absolutely condemns the internal use of it. However, it is recommended in ophthalmics, and defluctions of a sharp matter upon the eyes; and is generally ordered to be dissolved in milk for this purpose.

**SARCOLOGY**, is that part of anatomy which treats of the soft parts, viz. the muscles, intestines, arteries, veins, nerves, and fat. See **MUSCLES**, **INTESTINES**, &c.

**SARCOMA**, in surgery, denotes any fleshy excrescence. See **EXCRESCENCE**.

Sarcomata of the nose, eyes, &c. may be sometimes removed by caustics; but the extirpating them with the knife or scissors is the safest and most eligible method. The wound should be suffered to bleed a while, after which it may be washed with a collyrium made of aloes, tutty, and sugar of lead, mixed in rose-water.

**SARCOPHAGOUS MEDICINES**, in surgery, &c. are those which eat away proud flesh, and otherwise called caustics. See the article **CAUSTIC**.

**SARCOTICS**, in surgery, medicines which generate flesh in wounds. See the articles **WOUND** and **VULNERARIES**.

**SARDONYX**, in natural history, a genus of semi-pellucid gems, of the onyx-structure, zoned or tabulated, and composed of the matter of the onyx variegated with that of the red or yellow carnelian.

Of this stone there are several beautiful species; as, 1. The thin zoned red sardonyx; or whitish onyx with thin snow-white and red zones. 2. The broad zoned red sardonyx; or horny onyx, with punctuated zones. 3. The horny onyx, with whitish

whitish and yellow zones; and is properly the yellow sardonix and the chrysolite onyx of the ancients. 4. The orange-coloured sardonix; or bluish-white onyx, with orange-coloured and whitish zones.

**SAROTHTA**, in botany, a genus of plants, whose flower consists of five petals, of an obtuse, lanceolate, linear form, with five slender filaments topped with roundish antheræ: the fruit is an oblong, acute, unilocular capsule, which is coloured, having three valves, and contains a great number of small kidney-shaped seeds.

**SARRACENIA**, in botany, a genus of aquatic plants, whose flower-cup is double; the corolla consists of five ovate inflexed petals, with a great number of small stamina. The fruit is a roundish quinquelocular capsule, containing a number of small acuminate roundish seeds.

The plants of this genus are natives of North-America, and are much esteemed for the singular structure of their leaves and flowers, which are so very different from all others, as to have very little resemblance to those yet discovered.

**SARRASIN**, or **SARRAZIN**, in fortification, the same with *herse*. See the article *HERSE*.

**SARSAPARILLA**, in pharmacy, the root of the rough smilax of Peru, consisting of a great number of long strings hanging from one head: these long roots, the only parts made use of, are about the thickness of a goose-quill, or thicker, flexible, and composed of fibres running their whole length: they have a bitterish but not ungrateful taste, and no smell: and as to their medicinal virtues, they are sudorific and attenuant, and should be given in decoction, or by way of diet-drink.

**SARTORIUS**, in anatomy, is both an abductor and an elevator, serving to move the legs upward and forward, determining them to cross each other, as tailors sit with them, whence the name; it rises from the internal part of the anterior and superior spine of the ileum; and descending obliquely, is inserted into the upper and inner part of the tibia.

**SASSAFRAS-TREE**, in botany, a species of *laurus*; it grows in many parts of North-America, where it rises to the height of eight or ten feet; the branches are furnished with leaves about four inches long and three broad; others are deeply divided into three lobes, which are six inches long, and placed alternately upon pretty long foot-stalks; they are of a lucid green, and fall off in autumn: the flowers appear just below them, upon slender foot-stalks, each sustaining three or four small yellow flowers, which are each succeeded by a small oval berry, which when ripe is of a blue colour.

Sassafras is imported in large square blocks; it is said to be warm, aperient, and corroborant, and frequently employed with good success for purifying and sweetening the blood and juices; for which purpose an infusion, in the way of tea, is a very plea-

sant drink; and is a principal ingredient in the liquor called *salop*; the oil is very fragrant, and possesses most of the virtues of the wood.

**SATELLITE**, in astronomy, the same with a secondary planet, or moon; so called from its continually waiting upon or revolving round one of the primary planets. See the article *PLANET*.

**SATISFACTION**, in law, is the giving a recompence for some injury done; or the payment of money due on bond, judgment, &c.

**SATRAPA**, or **SATRAPES**, in Persian antiquity, denotes an admiral; but more commonly the governor of a province.

**SATTIN**, a glossy kind of silk stuff, the warp of which is very fine, and stands out so as to cover the coarser woof.

Some satins are quite plane, others wrought; some flowered with gold or silver, and others striped, &c.

The Chinese satins are most valued, because of their cleaning and bleaching easily, without losing any thing of their lustre: in other respects they are inferior to those of Europe.

**SATTINET**, a slight thin kind of sattin, commonly striped, and chiefly used by the ladies for summer night-gowns.

**SATURATION**, in chemistry, is the impregnating an acid with an alkali, or vice versa, till either will receive no more, and the mixture become neutral.

**SATURDAY**, the seventh or last day of the week, so called from the idol Seater, worshipped on this day by the ancient Saxons, and thought to be the same as the Saturn of the Latins. Saturday answers to the Jewish sabbath. See the article *SABBATH*.

**SATUREGIA**, savory, in botany. See the article *SAVORY*.

**SATURN**,  $\text{♄}$ , in astronomy, the remotest of the superior planets, which, by reason of its great distance from the sun, shines but with a feeble light. See the article *PLANET*.

**SATURN**, in chemistry, &c. an appellation given to lead. See the article *LEAD*.

**SATURN**, in heraldry, denotes the black colour, in blazoning the arms of sovereign princes. See *BLAZONING*.

**SATURNALIA**, in Roman antiquity, a festival observed about the middle of December, in honour of the god Saturn, whom Lucan introduces, giving an account of the ceremonies observed on this occasion thus: "During my whole reign, which lasts but for one week, no public business is done; there is nothing but drinking, singing, playing, creating imaginary kings, placing servants with their masters at table, &c. There shall be no disputes, reproaches, &c. but the rich and poor, masters and slaves, shall be equal," &c.

**SATURNINE**, an appellation given to persons of

of a melancholy disposition, as being supposed under the influence of the planet Saturn.

**SATYR**, in the heathen mythology, a fabulous kind of a demi-god, or rural deity, of the ancient Romans, represented with goat's feet, and sharp pricked up ears.

**SATYR**, or **SATIRE**, in matters of literature, a discourse or poem, exposing the vices and follies of mankind.

**SATYRIUM**, in botany, a genus of plants, whose flower consists of five oval oblong petals, the three outer and two inner forming the shape of a helmet, with a monophyllous nectarium placed between the division of the petals; the stamina are two short slender filaments, placed on the pistillum and terminated with oval antheræ, which have double cells inclosed in the upper-lip of the nectarium. The fruit is an unilocular, tricarinate, oblong capsule, containing a number of scabiform and very small seeds.

**SAUCISSE**, or **SAUSAGE**, in the military art, a long train of powder, sewed up in a roll of pitched cloth, about two inches in diameter, serving to set fire to the mines.

**SAUCISSON**, in fortification, a mass of large branches of trees bound together; and differing only from a fascine, as this is composed of small branches of twigs. See the article **FASCINE**.

Sauceçons are employed to cover the men, and to make epaulements.

**SAVIN**, *Sabina*, in botany, a plant which rises to about three or four feet in height, the branches inclining to a horizontal direction, and furnished with short pointed leaves, which have a disagreeable smell and an acrid burning taste: the flower and fruit are the same as the juniper, of which it is held a species by botanists. See the article **JUNIPER**.

Savin is a very powerful hystric, and so forcing, that, by some, it is put to the bad practice of procuring abortion; it is a great cleanser, and therefore very good in all obstructions of the viscera, where a constitution can bear its efficacy; and for the same reason it has obtained, among surgeons, the use of cleansing foul ulcers; it likewise is esteemed of great service against worms.

**SAVIOUR**, an appellation peculiarly given to Jesus Christ, as being the true Messiah, and Saviour of the world. See the article **MESSIAH**.

*Order of St. SAVIOUR*, a religious order in the Romish church, founded by St. Bridget, about the year 1345; and so called, from its being pretended that our Saviour himself dictated to the foundress its constitutions and rules.

**SAUNDERS**, *Santalum*, in botany. See the article **SANTALUM**.

**SAVORY**, *Saturegia*, in botany, a genus of plants, whose flower is monopetalous and ringent; the tube is cylindraceous, and the chaps single: there is no pericarpium, but the seeds, which are

four and roundish, are contained in the bottom of the cup.

The summer-favory is cultivated in gardens, by sowing the seeds in the spring, on a bed of light rich earth, and afterwards transplanted where they are intended to remain. The winter-favory may also be raised as the former, and also by slips.

They are both reckoned warm and discutive, and good against crudities of the stomach, asthma, and menstrual obstructions.

**SAVOY**, among gardeners, a well-known species of the brassica, or cabbage. See the article **CABBAGE**.

**SAURURUS**, in botany, a genus of plants, whose flower is destitute of a corolla; the cups are disposed in an oblong amentum, and are coloured and persistent: the stamina are seven long hairy filaments, topped with oblong erect antheræ: the fruit is an ovate unilocular berry, containing an oval seed.

**SAURURUS**, is also a name used by Plumier for several species of piper. See the article **PIPER**.

**SAUSAGE**, or **SAUCIDGE**, a popular food, prepared of some crude meat, usually either pork or beef, chopped small, seasoned, and put into a skin or gut, in the manner of a black-pudding.

**SAUVAGESIA**, in botany, a genus of plants, whose flower consists of five obtuse equal petals, with a nectarium cut into five parts: the fruit is an ovate acuminate capsule, having one cell, and opening at the top with five valves, containing a number of small seeds, placed in a longitudinal series.

**SAW**, an instrument which serves to cut into pieces several solid matters; as wood, ivory, stone, &c.

The best saws are of tempered steel ground bright and smooth; those of iron are only hammer-hardened: hence, the first, besides their being stiffer, are likewise found smoother than the last. They are known to be well hammered by the stiff bending of the blade; and to be well and evenly ground, by their bending equally in a bow.

The edge in which are the teeth is always thicker than the back, because the back is to follow the edge. The teeth are cut and sharpened by a triangular file, the blade of the saw being first fixed in a whetting-block. After they have been filed the teeth are set, that is, turned out of the right-line, that they may make the kerf or fissure the wider, that the back may follow the better.

The saws by which marble and other stones are cut have no teeth; these are generally very large, and are stretched out and held even by a frame.

**SAW-WORT**, *Serratula*, in botany. See **SERRATULA**.

**SAWING**, dividing timber, &c. by the application of a saw, either by the hand or mill.

**SAXIFRAGE**, *Saxifraga*, in botany, a genus of

of plants, with a rosaceous flower, consisting of five plane ovated petals: the fruit is an unilocular capsule, of an oval form, containing a great many seeds.

The tuberosities at the root of the white-flowered saxifrage are kept in the shops, under the name of saxifrage seeds: they are diuretic and attenuant; and therefore good in nephritic cases, and obstructions of the viscera and menses; some also recommend them in the jaundice and dropsy.

**SCABIOUS**, *Scabiosa*, in botany, a genus of plants, whose flower is composed of several floscules; the general corolla is equal, each proper one is monopetalous and tubular, slightly cut into four or five segments: there is no pericarpium: the seeds are single, being crowned with their proper cups, and placed on a convex receptacle.

The Indian or musk scabious is cultivated in gardens for ornament; it is propagated by sowing its seeds in the summer, and the year following the flowers will come out, and continue in beauty a long time.

The common wild scabious, which grows naturally in fields in many parts of England, is sometimes used in medicine; it stands recommended as aperient, sudorific, and expectorant, and has a place among the alexipharmics.

**SCAFFOLD**, among builders, an assemblage of planks and boards, sustained by tressels and pieces of wood fixed in the wall; whereon masons, bricklayers, &c. stand to work, in building high walls, &c. and plasterers, in plastering ceilings, &c.

Scaffold also denotes a timber-work, raised in the manner of an amphitheatre, for the more commodious viewing any shew or ceremony: it is also used for a little stage, raised in some public place, whereon to behead criminals.

**SCALA**, in anatomy, a name given to two canals in the cochlea of the ear. See the article **EAR**.

**SCALA**, in architecture, the same with stair case. See the article **STAIR**.

**SCALADO**, or **SCALADE**, in the art of war, a furious assault made on the wall or rampart of a city, or other fortified place, by means of ladders, without carrying on works in form to secure the men.

**SCALE**, a mathematical instrument, consisting of several lines drawn on wood, brass, silver, &c. and variously divided, according to the purposes it is intended to serve; whence it acquires various denominations, as the plain-scale, diagonal-scale, plotting-scale, Gunter's-scale, &c.

*Construction and Use of the Plain-SCALE.*—The plain-scale is an instrument much used in navigation, &c. for solving the several cases of sailing.

Having described the circle **DBCA** (plate **LXXVIII. fig. 6.**) and divided it into four quadrants, by the diameters **AB** and **CD** crossing each other at right-angles: 1. To project the line of tan-

gents, from the end **C** of the diameter **CD**, erect the perpendicular **CG**; then dividing the arch **CB** into nine equal parts, from the center **E**, through the several divisions of the quadrant **CB**, draw lines till they cut the perpendicular **CG**, which will thereby become a line of tangents.

2. For the semi-tangents, or half-tangents, let lines be drawn from the point **D**, through the same divisions upon the arch **CB**; and they will divide the radius **BE** into a line of semi-tangents, as is evident from Euclid, lib. 3. prop. 20.

3. For the secants, transfer the lines drawn from the center, through the several divisions of the quadrant **CB**, to form the line of tangents, to the line **EB** continued to **F**, and the line **EF** will be a line of secants.

4. For the sines, from the several divisions of the quadrant **CB**, let fall perpendiculars upon the radius **CE**, which will thereby be divided into a line of sines, to be numbered from **E** to **C** for the right sines, and from **C** to **E** for the versed sines; and these versed sines may be continued to  $180^\circ$ , if the same divisions be transferred on the other side of the center **E**.

5. For the chords, the arch **CB** being divided into nine equal parts, in the points **10, 20, 30, &c.** if lines be imagined to be drawn from **C** to these divisions, they will be the chords of their respective arches: wherefore, setting one foot of your compasses in the point **C**, and transferring the several lengths, **C 10, C 20, C 30, &c.** to the line **CB**, it will thereby be divided into a line of chords. These several lines, which in the figure are drawn but to every tenth degree, might in the very same manner be constructed to every degree, if the circle were made large enough to admit of ninety distinct divisions in the arch of one of its quadrants.

6. A line of rhumbs is thus constructed: divide the arch **DB** into eight equal parts, in the points **1, 2, 3, 4, &c.** then setting one foot of the compasses in **D**, transfer the several distances **D 1, D 2, D 3,** from the arch to the line **DB**; which by this means will be divided into a line of rhumbs, each of which will answer to an angle of  $11^\circ 15'$ .

7. To construct a line of longitude, divide the radius **EA** into sixty equal parts, marking every ten with their proper numbers; from these divisions, let fall perpendiculars upon the arch **AD**, and having drawn the line **AD**, with one of the compasses in **A**, transfer the several distances, where the perpendiculars cut the arch to the line **AD**, which will thereby be divided into a line of longitude.

8. To project the line of latitude, the radius **CE** being already divided into a line of sines, lay a ruler from the point **B** through each of the said divisions, and mark the points cut on the opposite arch **AC** with the numbers **10, 20, 30, &c.** then having drawn the line **AC**, with one foot of your compasses in **A**, transfer the several intersections of the arch

arch to the said line, which will thereby become a line of latitude.

9. To project the hour-line, draw the tangent I K equal and parallel to the diameter C D, and divide half the arch of each quadrant A C, and A D, from the point A, into three equal parts, which will be  $15^\circ$  each part, for the degrees of every hour from twelve to six; each of which parts are to be again subdivided into halves and quarters, &c. then drawing lines from the center E, through each of their divisions and subdivisions, till they cut the tangent I K, the said tangent will thereby be divided into a line of hours.

10. To the above lines may be added a line of inclination of meridians, which is projected in the same manner as the hour-line; being only divided into degrees, instead of time, every fifteen degrees being equal to an hour.

Now, if these lines, with their respective divisions, be transferred to a scale, and there also be added a line of equal parts, the instrument called the plain-scale, will be completed, as in *fig. 7*; and as to the uses of these lines, those of tangents, semi-tangents, and secants, serve to find the centers and poles of projected circles, in the stereographic projection of the sphere, &c. the line of sines serves for orthographic projection of the sphere; the line of chords serves either to lay down any angle, or measure the quantity of one already laid down; the line of rhumbs serves with more readiness than the line of chords, to lay down or measure the angle of a ship's course in navigation; the line of longitude being laid down on the scale, contiguous to a line of chords of the same radius, and numbered the contrary way, shews by inspection, how many miles there are in a degree of longitude in each parallel of latitude, reckoning the latitude upon the line of chords, and the miles of longitude upon the line of longitude; the two lines of latitudes and hours, are used conjointly, and serve very readily to mark the hour-lines in the construction of dials, on any kind of upright planes. See the articles NAVIGATION, TRIGONOMETRY, &c.

*Diagonal-Scale*, is projected thus: first draw eleven parallel lines at equal distances (see plate LXXVIII. *fig. 8*.) the whole length of which being divided into a certain number of equal parts, according to the length of the scale, by perpendicular parallels, let the first division be again subdivided into ten equal parts, both above and below; then drawing the oblique lines from the first perpendicular below to the first subdivision above, and from the first subdivision below to the second subdivision above, &c. the first space shall thereby be exactly divided into one hundred equal parts; for as each of these subdivisions is one-tenth part of the whole first space or division, so each parallel above it is one-tenth of such subdivision, and consequently one-hundredth part of the whole first space; and if there be ten of

the larger divisions, one-thousandth part of the whole scale.

If, therefore, the larger divisions be accounted units, the first subdivisions will be tenth parts of an unit; and the second subdivisions, marked by the diagonals on the parallels, hundredth parts of an unit.

Again, if the larger divisions be reckoned tens, the first subdivisions will be units, and the second subdivisions tenth parts: and if the larger divisions be accounted hundredths, the first subdivisions will be tens, and the second units; and so on. See the article PLOTTING.

*Gunter's-SCALE*, an instrument so called, from Mr. Gunter, its inventor, and is generally made of box.

There are two sorts, the long-Gunter and the sliding-Gunter, having both the same lines, but differently used; the former with the compasses, the latter by sliding.

The lines now generally delineated on those instruments are the following, viz. a line of numbers, of sines, tangents, versed sines, sine of the rhumb, tangent of the rhumb, meridional parts, and equal parts; which are constructed after the following manner:

The line of numbers is no other than the logarithmic scale of proportionals, wherein the distance between each division is equal to the number of mean proportionals contained between the two terms, in such parts as the distance between 1 and 10 is 1000, &c. = the logarithm of that number. Hence it follows, that, if the number of equal parts expressed by the logarithm of any number, be taken from the same scale of equal parts, and set off from 1 on the line of numbers, the division will represent the number answering to that logarithm.

Thus, if you take .954, &c. (the logarithms of 9) of the same parts, and set it off from 1 towards 10, you will have the division standing against the number 9. In like manner, if you set off .903, &c. .845, &c. .778, &c. (the logarithms of 8, 7, 6,) of the same equal parts from 1 towards 10, you will have the divisions answering to the numbers, 8, 7, 6. After the same manner may the whole line be constructed.

The line of numbers being thus constructed, if the numbers answering to the natural sines and tangents of any arch, in such parts as the radius is 10000, &c. be found upon the line of numbers, right against them will stand the respective divisions answering to the respective arches; or, which is the same thing, if the distance between the center and that division of the line of numbers, which expresses the number answering to the natural sine or tangent of any arch, be set off on its respective line from its center towards the left hand, it will give the point answering to the sine or tangent of that arch: thus the natural sine of 30 degrees being 5000, &c. if

the distance between the center of the line of numbers (which in this case is = 10000, &c. = the radius) and the division, on the same line representing 5000, &c. be set off from the center, or 90 degrees, on the line of lines, towards the left hand; it will give the point answering to the sine of 30 degrees. And after the same manner may the whole line of sines, tangents, and versed sines, be divided. See the article GUNTER.

The line of sines, tangents, and versed sines, being thus constructed, the line sine of the rhumb, and tangent of the rhumb, are easily divided; for, if the degrees and minutes answering to the angle which every rhumb makes with the meridian, be transferred from its respective line to that which is to be divided, we shall have the several points required: thus if the distance between the radius or center, and sine of 45 degrees = the fourth rhumb, be set off upon the line sine of the rhumb, we shall have the point answering to the sine of the fourth rhumb; and after the same manner may both these lines be constructed.

The line of meridional parts is constructed from the table of meridional parts, in the same manner as the line of numbers is from the logarithms.

The lines being thus constructed, all problems relating to arithmetic, trigonometry, and their depending sciences, may be solved by the extent of the compasses only; and, as all questions are reducible to proportions, the general rule is, to extend the compasses from the first term to the second, and the same extent of the compasses will reach from the third to the fourth; which fourth term must be so continued as to be the thing required, which a little practice will render easy.

SCALE, *Scala*, in music, is a denomination given to the arrangement of the six syllables invented by Guido Aretine, *ut, re, mi, fa, sol, la*, called also gamut. See the article GAMUT.

SCALE, in geography and architecture, a line divided into equal parts, placed at the bottom of a map, or plan, to serve as a common measure for all the parts of a building, or all the distances or places of a map.

SCALED, or SCALENOUS TRIANGLE, *Scalenum*, in geometry, a triangle whose sides and angles are unequal. See the article TRIANGLE.

SCALenus, in anatomy, a name given to one of the flexors of the neck.

This muscle has its origin from the first, second, and sometimes third rib; and is inserted into the apophyses of the vertebrae of the neck, and is by some justly referred to the number of the elevators of the thorax.

The scalenus is frequently divided into three parts, hence some anatomical writers have made three muscles of it, under the names of the first, second, and third scalenus.

SCALLOP, or IRISH-SCALLOP, in ichthyology, a name for the blue-ribbed red pecten, variegated with white; being about two inches long, and nearly as much in breadth, having on the surface about fifteen broad depressed ribs, placed at nearly equal distances from one another; the valves are very little elevated, and the ears are moderately large, and one a little bigger than the other. See the article PECTEN.

SCALPEL, in surgery, a kind of knife used in anatomical dissections and operations in surgery. See the article KNIFE.

SCALPER, or SCALPING-IRON, a surgeon's instrument used for scraping foul carious bones.

SCAMMONY, in the materia medica, is a concreted vegetable juice of a plant of the same name, partly of the resin and partly of the gum kind, of which there are two sorts, distinguished by the names of the places from whence they are brought.

The Aleppo scammony is of a spongy texture, light and friable: it is of a faint disagreeable smell, and its taste is bitterish, very nauseous, and acrimonious.

The Smyrna scammony is considerably hard and heavy, of a black colour, and of a much stronger smell and taste than the former, otherwise it much resembles it.

In general, scammony is to be chosen friable and easily powdered, glossy when fresh broken; such as grows white on being moistened with the spittle; free from dirt, sand, or other foulnesses, and not too violently acrimonious in its taste.

Scammony is in great esteem and frequent use, and would be more so, if it were more to be depended upon: but there is so much difference in the purgative virtue of some masses of it, and that of others, that it is seldom to be depended upon alone in extemporaneous practice. It is, however, an ingredient in many compositions of the drops; and these are prescribed with other cathartics, for purging off serous humours. It is, in general, however, a better purge for robust people, than for those of more delicate constitutions; though with the correctives with which it is joined, it is given with safety to children.

The chemical writers have given us many preparations of scammony, among which are a tincture and a resin; but the scammony in substance is preferable to either; for they both irritate more, and yet purge less; the resin itself given in an equal dose with the crude scammony, will give fewer stools, and those attended with worse gripings.

The ancients used scammony externally for cutaneous eruptions, and to soften hard tumours; but at present it is used only as a purge. For the preparation of scammony by baking it in a quince, see DIAGRYDIUM.

SCANDALUM MAGNATUM, in law, is a defamatory

famatory speech or writing to the injury of a person of dignity: for which a writ that bears the same name is granted for the recovery of damages. By statute, no person is either by writing or speaking to publish any false or scandalous news of any lord, prelate, officer of the government, judge, &c. on pain of imprisonment, till he produce his author; and if the same be published in a libel, the publisher is indictable, and may be fined and imprisoned.

**SCANDIX**, shepherd's needle; in botany, a genus of umbelliferous plants, the general corolla of which is difform and radiated, and the proper flower consists of five heart-shaped petals; those which form the disc are abortive; there is no pericarpium, but the flowers are succeeded by two very long grains, not unlike needles, that are convex and furrowed on one side, and flat on the other. This genus includes the chervil which grows in gardens; it is diuretic, and recommended by some against the gravel.

**SCANNING**, *Scanfio*, in poetry, the measure of a verse by feet, in order to see whether or no the quantities be duely observed.

The term is chiefly used in regard to the Greek and Latin verses. Thus an hexameter verse is scanned, by resolving it into six feet; a pentameter, by resolving it into five feet, &c.

**SCAPE-GOAT**, in Jewish antiquity, the goat which was set at liberty on the great day of expiation. See **EXPIATION**.

Spencer is of opinion, that the scape-goat was called azazel, because it was sent to azazel, i. e. the devil; the reasons of which ceremony, he takes to be these: 1. That the goat, loaded with the sins of the people, and sent to azazel, might denote the miserable condition of sinners. 2. The goat was sent thus loaded to the dæmons, to shew that they were impure, and to deter the people from worshipping them. 3. That the goat sent to azazel sufficiently expiating the sins of the Israelites, they might the more willingly abstain from the expiatory sacrifices of the heathens.

**SCAPHISM**, *σκαφισμός*, in Persian antiquity, a kind of torture, or capital punishment; which consisted in locking the criminal in a sort of box made of the trunk of a tree, with only five holes, for his head, arms, and legs to come through; then anointing the parts with honey and milk, in order to invite the flies, &c. he was exposed to the sun; and, in this unhappy situation he continued till death put an end to his misery.

**SCAPHOIDES**, in anatomy, the same with navicular os. See the article **NAVICULARE OS**.

**SCAPULA**, in anatomy, the shoulder-blade, a triangular bone, situated on the outside of the ribs, and commonly extended from the second to the seventh rib; its superior posterior angle, when it is in the least straining position, being about three inches from the spinal processes of the vertebrae,

while the long side between that angle and the inferior one is stretched obliquely forward as it descends, having nothing between it and the ribs, except the thin extremities of some muscles; but as the scapula advances forwards to its articulation with the arm bone, its distance from the ribs increaseth.

**SCAPULAR**, *Scapulares*, in anatomy, a name given to two pair of arteries, and as many veins; the arteries are the external scapular artery, which is sent from the subclavians to the external part of the scapula; and the internal scapular artery, which arises from the axillary arteries, and goes to the parts that lie under the scapula. The scapular veins, which are also external and internal, arise in like manner from the subclavians.

**SCAPULAR**, or **SCAPULARY**, a part of the habit of several religious orders in the church of Rome, worn over the gown, as a badge of peculiar veneration for the blessed Virgin. It consists of two narrow breadths or slips of cloth, covering the back and the breast, and hanging down to the feet.

**SCAPUS**, in architecture, the fust or shaft of a column.

In botany, the same word is used for the strait stalk or stem of a plant, standing upright like a pillar or column.

**SCARABÆUS**, the beetle, in zoology, a numerous genus of insects, of the coleoptera-order: the antennæ of the beetles are of a clavated figure, and fissile longitudinally; and their eggs all hatch into hexapode worms, from which the young beetles are afterwards produced.

**SCARIFICATION**, in surgery, the operation of making several incisions in the skin by means of lancets, or other instruments, particularly the cupping instrument.

**SCARLET**, a beautiful bright red.

In painting in water-colours, minium mixed with a little vermilion produces a good scarlet; but if a flower in a print is to be painted of a scarlet-colour, the lights as well as the shades should be covered with minium, and the shaded parts finished with carmine, which will produce an admirable scarlet.

**SCARLET-FEVER**, the same with miliary fever. See **MILIARY-FEVER**.

**SCARP**, in fortification, is the interior talus, or slope of the ditch next the place, at the foot of the rampart.

**SCARP**, in heraldry, the scarf which military commanders wear for ornament.

**SCAVANT**, a term purely French, signifying learned; it is little used in our language, except in the phrase *Journal des Scavans*, a journal of the works of the learned, published monthly at Paris.

**SCAVENGERS**, two officers annually chosen in every parish in London and its suburbs by the church-wardens, constables, and other inhabitants, to hire persons called rakers, with carts, to clean the

the streets, and carry away the dirt and filth, with the ashes and dust from every house. For which purpose a scavenger's tax may be made and levied on the inhabitants, being allowed by the justices of the peace; but it must not exceed 4 d. in the pound, of the rent paid for the houses.

**SCENE**, *Scena*, in its primary sense, denoted a theatre, or the place where dramatic pieces, and other public shews were exhibited: for it does not appear that the ancient poets were at all acquainted with the modern way of changing the scenes in the different parts of the play, in order to raise the idea of the persons represented by the actors being in different places.

The original scene for acting of plays was as simple as the representations themselves; it consisted of only a plane plot of ground proper for the occasion, which was in some degree shaded by the neighbouring trees, whose branches were made to meet together, and their vacancies supplied with boards, sticks, and the like; and to complete the shelter, these were sometimes covered with skins, and sometimes with only the branches of other trees newly cut down, and full of leaves. Afterwards more artificial scenes or scenical representations were introduced, and paintings used instead of the objects themselves. Scenes were then of three sorts, tragic, comic, and satyric. The tragic scene represented stately magnificent edifices, with decorations of pillars, statues, and other things suitable to the palaces of kings: the comic exhibited private houses with balconies and windows, in imitation of common buildings: and the satyric was the representation of groves, mountains, dens, and other appearances; and these decorations either turned on pivots, or slid along grooves, as those in our theatres.

To keep close to nature and probability, the scene should never be shifted from place to place in the course of the play: the ancients were pretty severe in this respect, particularly Terence, in some of whose plays the scene never shifted at all, but the whole is transacted at the door of some old man's house, whither, with inimitable art, he occasionally brings the actors. The French are pretty strict with respect to this rule; but the English pay very little regard to it.

Scene is also a part or division of a dramatic poem. Thus plays are divided into acts, and acts are again subdivided into scenes; in which sense the scene is properly the persons present at, or concerned in the action on the stage at such a time: whenever, therefore, a new actor appears, or an old one disappears, the action is changed into other hands; and therefore a new scene then commences.

**SCENIC GAMES**, among the ancients, were entertainments exhibited on the *scena* or theatre,

including plays, dancing, and other theatrical performances.

The Romans were four hundred years without any scenic games, and at their institution, some actors were sent for from Histruria; who, without reciting any thing, danced to the sound of instruments; at length they began to rehearse verse, from thence they proceeded to plays, and thus by degrees, growing more and more perfect, their scenical shews were at last represented, with a justness and magnificence beyond every thing the world had ever seen.

**SCENOGRAPHY**, in perspective, the representation of a body on a perspective plane; or, a description thereof in all its dimensions, such as it appears to the eye. See the article **PERSPECTIVE**.

The *ichnography* of a building, &c. represents its plan, or ground-work; the *orthography*, is a view of the front, or one of its sides; and the *scenography*, is a view of the whole building, front, sides, height, and all, raised on the geometrical plan.

**SCENOPEGIA**, in Jewish antiquity, the same with the feast of tabernacles. See the article **TABERNACLE**.

**SCEPTER**, a kind of royal staff, or battoon, borne by kings, on solemn occasions, as an ensign of command and authority.

**SCEPTER**, in astronomy, one of the six new constellations of the southern hemisphere, consisting of seventeen stars.

**SCEPTICISM**, the doctrines and opinions of the sceptics, whose distinguishing tenet was, that all things are uncertain and incomprehensible, and that the mind is never to assent to any thing, but to remain in perpetual doubt and suspense.

**SCHEAT**, or feat, a fixed star of the second magnitude, in the junction of the leg with the left shoulder of Pegasus. See the article **PEGASUS**.

**SCHEUCZERIA**, in botany, a genus of plants, whose flower is apetalous; the calyx is divided into six oblong acute segments, and contains six very short capillary filaments, topped with erect obtuse antheræ: the fruit consists of three roundish compressed capsules, containing in each an oblong foliary seed.

**SCHINUS**, in botany, a genus of plants, whose flower consists of five patent petals, and ten stamens; the fruit is a globose berry, containing a round seed.

**SCHISM**, a separation, or breaking off from communion with any church; on account of some disagreement in matters of faith or discipline.

**SCHOENUS**, in botany, a genus of plants, whose flower consists of six lanceolated, acute, and connivent petals, unequal in size and situation, disposed in a kind of imbricated manner, and the exterior ones shorter than the rest: there is no pericarpium; the seed is single, of an oval but somewhat

what triquetrous form, largest in the upper part, and contained till ripe in the corolla.

This genus comprehends the cyperella and melanofchoenus of Micheli.

**SCHOLASTIC**, σχολαστικος, something belonging to the schools. See the article **SCHOOL**.

Scholastic divinity, is that part or species of divinity which clears and discusses questions by reason and arguments; in which sense it stands, in some measure, opposed to positive divinity, which is founded on the authority of fathers, councils, &c.

The school-divinity is now fallen into the last contempt, and is scarce regarded any where, but in some universities, where they are still by their charters obliged to teach it.

**SCHOLIAST**, or **COMMENTATOR**, a grammarian, who writes scholia, that is, notes, glosses, &c. upon ancient authors, who have written in the learned languages. See the next article.

**SCHOLIUM**, a note, annotation, or remark, occasionally made on some passage, proposition, or the like.

This term is much used in geometry, and other parts of mathematics, where after demonstrating a proposition, it is customary to point out how it might be done some other way, or to give some advice, or precaution, in order to prevent mistakes, or add some particular use, or application thereof.

**SCHOOL**, *Schola*, a public place, wherein the languages, humanities, or other arts and sciences are taught: thus we say, grammar-school, writing-school, &c. See the article **SCHOLASTIC**.

**SCHREBERA**, in botany, a genus of plants, whose flower is monopetalous and funnel-shaped, with the edge cut into five oblong obtuse segments: the stamina are five slender filaments, topped with roundish antheræ, and inserted in the chaps of the corolla: the fruit is a depressed bilocular drupe, containing two seeds.

**SCHWALBEA**, in botany, a genus of plants, whose flower is monopetalous and ringent; the tube is the length of the cup, with the limb erect; the superior lip is upright, concave and intire, and the lower one is trifid and obtuse; the fruit is a bilocular capsule, containing two small roundish seeds.

**SCIARRI**, in natural history, the matter which runs down in burning torrents from the craters of volcanos, and which probably contains mineral and metallic particles, it being ponderous and hard.

It seems to be the result of many sorts of minerals melted together.

**SCIATICA**, the hip-gout, a violent and obstinate pain in the hip, chiefly in the joint, where the head of the thigh-bone is received into the acetabulum of the coxendix.

This pain will sometimes extend itself to the lower part of the loins, to the thigh, leg, and even the extremity of the foot, yet outwardly there is no swelling, no inflammation, nor change of colour

in the skin; sometimes there is such a spasm of the muscles on the side affected, that the patient cannot stand upright without the utmost pain.

This disorder may arise from the same cause with that which produces the gout; but it is most generally the effect of catching cold, or being exposed to the open air; it may also be occasioned by contusions and venereal disorders. See the article **GOUT**, &c.

After a gentle cathartic, or clyster, bleeding will be proper, especially in the ankle; also leeches applied to the hæmorrhoidal veins, have been found beneficial; strong purges are hurtful, but mercurius dulcis with scammony, or some other purgative, will be of service; some give mercurial emetics, and afterwards mercurial purgatives, repeated twice a week, or as occasion requires, for six times.

If the patient is old, lenient purgatives will be most proper, and on intermediate days a dose of calomel, which is afterwards to be purged off, and so repeated alternately for some time.

Outwardly, the linamentum saponaceum is recommended by Reverius, Junker, and others; the part is to be anointed with it near the fire. Riverius says, he has known an obstinate sciatica cured in one day, by applying six cupping-glasses on and about the part affected, and then anointing it with oil of bricks hot, and afterwards covering it with a linen cloth, made very hot. Zacutus Lusitanus affirms, that the sciatica has been cured in a few hours, by applying eight or ten leeches to the part affected. Baglivi observes, that if nothing else will do, recourse must be had to caustics, particularly the leaves of ranunculus, or a mixture of quick-lime and soft soap.

**SCIENCE**, *Scientia*, in philosophy, denotes any doctrine, deduced from self-evident and certain principles, by a regular demonstration.

**SCILLA**, the squill, in botany, a genus of plants, whose flower consists of six ovate deciduous petals, which spread open, and contain six subulated filaments, terminated with oblong incumbent antheræ: the fruit is a smooth oval three-furrowed capsule, with three cells, which contain a number of roundish seeds.

This genus includes the starry-hyacinth.

The roots of the common squill are brought from the Levant and Spain every year, and used in medicine: those should be chosen that are fresh, of a middle size, sound, heavy, firm, and full of a clammy, bitter, acrid juice: they are excellent in disorders of the lungs caused by a viscous phlegm, and act with great efficacy in fits of the moist asthma, and in a disposition to the dropsy: the most usual form in which it is prescribed, is that of the oximel, made of a strong infusion of the root in vinegar, or made into a syrup of honey.

**SCIOPTIC**, a sphere or globe of wood, with a circular hole, or perforation, wherein a lens is placed.

placed. It is so fitted that, like the eye of an animal, it may be turned round every way, to be used in making experiments of the darkened room. See **CAMERA OBSCURO**.

**SCIRE-FACIAS**, in law, a judicial writ most commonly issued to call a person to shew cause to the court whence it issues, why execution of a judgment passed should not be made out; as where a plaintiff has recovered debt or damages in a court of record, and does not take out execution in a year and a day after judgment recovered: in that case, he shall have this writ to summon the defendant to shew cause why execution should not be had against him upon the said judgment; which, if the defendant does not, judgment is given and the plaintiff shall have execution.

**SCIRPUS**, in botany, a genus of plants, whose flower hath no corolla; the calyx is a spike, imbricated all round, and the scales are oval; there are three filaments, topped with oblong antheræ; the germen is small, and there is no pericarpium: the seed is single, three-cornered, and pointed, and the hairs are longer than the cup.

This genus comprehends the club-rush and bul-rush.

**SCIRRHUS**, *σκιρρος*, in surgery and medicine, a hard tumour of any part of the body, void of pain, arising from the inspissation and induration of the fluids contained in a gland, though it may appear in any other part, especially in the fat, being one of ways wherein an inflammation terminates.

**SCISSARS**, a well-known instrument for cutting any thing asunder. See the article **FORCEPS**.

**SCLAREA**, clary, in botany, a genus of plants, according to Tournefort; but comprehended by Linnæus among the sages. See the articles **SALVIA** and **SAGE**.

The common garden clary is a biennial plant, the lower leaves of which are large, rough, wrinkled, and of an oblong heart-shaped form, ending in blunt points, and sawed on their edges: the stalks are large, four-cornered, and clammy, and rise about two feet high; they are furnished with leaves of the same shape, but less: the flowers are disposed in loose spikes on the top of the stalks; they are of a pale blue colour, placed in whorles, and are of the lip kind, like those of sage; they come out in June or July, and the seeds ripen in Autumn.

The whole plant has a very strong smell, and is said to be good in female weaknesses: the shops have a spirit under its name, which is drawn from an infusion of the herb in spirit of wine, which is very pleasant and a good cordial.

**SCLERANTHUS**, knawel, in botany, a genus of plants, whose flower hath no corolla, but consists of a monophyllous tubulated cup, cut half way into five acute segments, and contains ten subulated filaments, topped with roundish antheræ: the fruit

is a very narrow ovate capsule, inclosing two seeds, convex on one side and flat on the other.

The hoary perennial knawel is the plant, at the roots of which is found the *coccus polonicus*, a very valuable scarlet dye. See the article **COCCUS**.

**SCLEROTICA**, in anatomy, one of the tunics or coats of the eye: it is hard, opaque, and extended from the cornea to the optic nerve; its fore part is transparent and called the cornea.

**SCLEROTICS**, medicines proper to harden and consolidate the flesh of the parts to which they are applied; as purslain, house-leek, flea-wort, garden night-shade, &c.

**SCOLOPAX**, the wood-cock, in ornithology, a species of *numenius*, with a black line on each side the head; it is a very beautiful and delicate bird, somewhat smaller than the partridge. See the article **NUMENIUS**.

**SCOLOPENDRA**, in zoology, an insect with a very slender and long body, and furnished with a vast number of legs.

According to Dale, it is sometimes used as a depilatory, boiled in wine.

**SCOLYMUS**, the golden-thistle, in botany, a genus of plants, whose flower is compound, imbricated, and uniform, consisting of a number of ligulated linear corollulæ: there is no pericarpium, but the cup contains the seeds, which are solitary, oblong, triangular, and placed on a paleaceous receptacle.

**SCONCE**, in fortification, a small field fort, built for the defence of some pass, or other post. See the article **FORT**.

**SCOPARIA**, in botany, a genus of plants, whose flower is monopetalous, rotated, patent, and divided at the brim into four segments: the fruit is an oblong, conic, acuminate capsule, with one cell, opening with two valves, and contains a number of oblong seeds.

**SCORBUTUS**, the scurvy, in medicine. See the article **SCURVY**.

**SCORDIUM**, water-germander, in botany, a plant which hath a fibrous, creeping, perennial root, from which arise several branches, that are square, hairy, hollow, branched, and creep on the ground; they are furnished with oblong, wrinkled, hairy leaves, dentated on their edges, having a strong garlic odour with a bitter taste: the flowers grow from the places where the leaves join the stalk; they are small, and consist of a small labiated petal of a reddish colour, and appear in July; they are succeeded by four small roundish seeds, placed in the bottom of the cup: this plant grows on moist marshy places, on the side of ditches, &c.

It is looked upon as aperient, diaphoretic, and pectoral, and is justly esteemed a good alexipharmic, and accordingly is prescribed in malignant disorders; it is a principal ingredient in the *confectio Fracastorii*,

torii, which takes its name of diascordium from it. See the article DIASCORDIUM.

This plant is comprehended by Linnæus among the teucuriums. See TEUCURIUM.

SCORIA, dross, among metallurgists, is the recrement of metals in fusion; or, more determinately speaking, is that mass which is produced by melting metals and ores, and when cold is brittle, and not dissoluble in water, being properly a kind of glass.

SCORIFICATION, in metallurgy, is the art of reducing a body, either entirely, or in part, into scoria. See the preceding article.

SCORPIO, the scorpion. See SCORPION.

SCORPIOIDES, in botany, the same with scorpiurus. See the article SCORPIURUS.

SCORPION, *Scorpio*, in zoology, a genus of wingless insects, the body of which is of an oval

figure; the tail is long and slender, and the whole body covered with a firm and somewhat hard skin; the eyes are eight in number, two of which are placed contiguous, and six side-ways; the legs are eight; and there is also a pair of claws at the head, and a pointed weapon at the extremity of the tail.

The great yellowish Barbary scorpion, with eight denticulations, when full grown, measures six or seven inches in length: there are several other species.

SCORPION, *Scorpio*, in astronomy, the eighth sign of the zodiac, denoted by this character, ♏. See the articles SIGN and ZODIAC.

The stars in Scorpio, in Ptolemy's catalogue, are twenty; in that of Tycho, ten; but in that of Mr. Flamsteed, forty-nine: the longitudes, latitudes, magnitudes, &c. are as follow:

### Names and Situations of the Stars.

| Names and Situations of the Stars.         |       |       |       | Signs. | Longitude. | Latitude. |      | Magn. |   |

SCORPION, in the ancient art of war, an engine chiefly used in the defence of the walls of fortified places, by throwing arrows, fire-balls, or great stones.

SCORPION, *Seda*, in botany. See the article CORONILLA.

SCORPIURUS, rough caterpillars, in botany, a genus of plants, producing papilionaceous flowers; the vexillum is roundish, emarginated, reflexed and patent; the alæ are almost oval, loose, with obtuse appendices; the carina is half-moon shaped, the belly gibbous, pointed, erect, and divided into two parts: the fruit is an oblong, taper, coriaceous, rough-channelled pod, much resembling a caterpillar, containing several cells, each inclosing a roundish seed.

The plants of this genus are annual, and propagated by sowing their seeds in the spring where they are intended to perfect themselves; in June the flowers will appear, which are succeeded by pods, so much like caterpillars, that a person at a small distance would imagine they were real caterpillars feeding on the plants.

This genus comprehends the scorpoides and cam-poides of authors.

SCORZONERA, Viper's-grafs, in botany, a genus of plants, whose flower is compound, imbricated and uniform, consisting of a number of monopetalous, ligulated, linear, hermaphrodite corollulæ, which are indented at their extremity in five parts, and contain five short capillary filaments, which are terminated with cylindraceous tubulose antheræ; there is no pericarpium, but the seeds, which are solitary, oblong, striated, and crowned

with a plumose down, are contained in the imbricated cup, on a naked receptacle. The broad-leaved scorzonera is cultivated in gardens for culinary and medicinal purposes, and is propagated by sowing the seeds in the spring on light earth, and afterwards thinning the plants out to about six or eight inches asunder. The root of this plant abounds with a milky juice of a bitterish subacid taste, and is said to strengthen the stomach, and promote urine and sweat, and boiled is reckoned a very good food.

SCREW, or SCREW, *Cochlea*, one of the five mechanical powers. A screw is a cylinder cut into several concave surfaces, or rather a channel or groove made in a cylinder, by carrying on two spiral planes the whole length of the screw, in such a manner, that they may be always equally inclined to the axis of the cylinder in their whole progress, and also always inclined to the base of it in the same angle.

The screw may also be considered as a wedge carried round a cylinder, which in that case is called the arbor of the screw; the wedge, so carried on, making what is called the thread of the screw; as may be seen in plate LXXX. fig. 1, 2, 3, 4, 5. The arbor of the screw being A B in fig. 1, and a c b d in fig. 2, as if the cylinder A C B D was inscribed within the screw. Here, we may see the manner how a screw is made; for if it be cut out of the cylinder P H I Q, then H K L M N O P is a spiral line going about the cylinder, making the prominent part to be left of the said cylinder; and b k l m n o, the line marking the depth to which the screw is to be cut, supposing the same line to go round the inner cylinder or arbor A B C D, though

not

SCORPIO

J. Lodge sculp.

not expressed here, to avoid confusion; and then  $bL/Nn$ , &c. will represent the prominent part or thread of the screw. Now, if instead of cutting the hollows,  $HbL$ ,  $L/N$ ,  $NnP$ , into the cylinder  $PHIQ$ , a continued wedge be fixed to a smaller cylinder, as  $ACBD$ , or rather  $acbd$ , the same kind of screw will be made, and  $acbd$  will be the arbor of that screw. Sometimes the most prominent part of the thread, as  $LN$ , &c. is not sharp but flat, and then the thread is called a square thread, as in *fig. 5.* which represents the section of such a screw. This sort of thread is not used in wood, but in iron, and in other metals; it is of good service, being commonly more durable, and raising the weight with more ease than the sharp thread.

*Force of the SCREW.* To make an estimate of the force of the screw, which may be compared either to an inclined plane, or to a wedge, according as its arbor does or does not advance in a progressive motion whilst it turns round its axis to raise or stop a weight, or to press bodies together, which are the several uses of a screw, let us take a flexible wedge, as, for example, one of paper, and coil it round a cylinder, *fig. 1.* as is represented in the figure, where  $AB$  is the arbor,  $CID$  one thread or helix,  $DHE$  another, and  $ETG$  part of the wedge left to shew the proportion between the power that turns the screw and the weight  $W$ .

If the weight is pushed up the wedge, (or, which is the same thing, raised perpendicularly by the wedge slipping under it) from  $F$  to  $H$  in the direction  $Ww$ , then will  $HG$  be the velocity of the weight, and  $GT$  the velocity of the power, which is the case of the inclined plane becoming a wedge; and this will be the analogy for the screw thus acting.

As a circle whose diameter is  $Hb$ : to  $HI$  the distance of two threads:: (or as the base  $FG$ : to the perpendicular  $HG$ ::) so is the weight: to the power applied to the arbor at  $A$ , to raise a weight up the thread  $HDI$ .

*N. B.* We suppose the diameter of the arbor at  $A$  and of the screw at  $H$  nearly equal.

This is the case of *fig. 4.* where the moveable plank  $DK$  is carried down, by turning round the heads  $GG$  of the screws  $AB$  and  $CD$ , in order to press strongly the bodies placed between the planks  $DK$  and  $ML$ , whilst the piece  $HI$ , fixed on the upper plank, is either guided through a hole, or, being only looked at, serves to shew whether the plank  $KD$  be brought down horizontally, as the screws are turned. When long levers are thrust into the square holes at the heads of the screws, the force of the screw is much increased, and then the weight will be to the power:: as the circumference of the circle described by that part of the lever to which the hand is applied: to the distance between two threads. Wherefore, as the

circumference of the circle is to the distance of two thirds of an endless screw:: so is the resistance of the teeth of the wheel: to the power applied to the handle.

*Archimedes's SCREW*, in hydraulics, a kind of spiral pump, for raising water, so called from its inventor Archimedes.

It consists of a long cylinder, with a hollow pipe, tube, or groove coiled round it, as represented in *fig. 6.* where  $AB$  represents the cylinder, and  $CD$  the tube open at each end. It is placed in an oblique position to the horizon, with the lower end in the water to be pumped away, the other end being supported on the lower part of the winch  $IK$ , by which the screw and cylinder are turned round.

As soon as the screw is immersed in the water, it immediately rises therein by the orifice  $C$  to the level of the surface of the water  $EF$ ; and if the point of the helix or spiral, which in the beginning of the motion is coincident with the surface of the water, happens not to be on the lower side of the cylinder, the water will upon the motion of the screw, move on in the spiral, till it comes to the point which is on the other side, and coincident with the surface of the water; when it is arrived at that point, which suppose at  $O$ , it cannot afterwards possess any other part of the spiral than that which is upon the lowest part of the cylinder; for it cannot move from  $O$  towards  $H$  or  $G$ , because they are situated higher above the horizon; and since this will constantly be the case, after the water in the spiral has obtained the point  $O$ , it is plain that it must always be on the under side of the cylinder.

But because the cylinder is in motion, every part of the spiral screw, from  $O$  to  $D$ , will, by degrees, succeed to the said under part of the cylinder; the water, therefore, in the spiral, must succeed to every part thereof, from  $O$  to  $D$ , as it comes on the lower side; that is, it must ascend on the lower part of the cylinder through all the length of the pipe, till it comes to the orifice  $D$ , where it will run out, as having nothing farther to support it. Hence it appears how much those gentlemen are mistaken who, affecting the wonderful, say, 'That the water ascends by descending;' whereas, if they would have made the most of the wonder, they might have truly said, 'That the water ascends because it cannot ascend,' i. e. that it ascends one way because it cannot ascend another; but then the wonder is lost.

*Endless or Perpetual SCREW*, one so fitted in a compound machine, as to turn a dented wheel; so called, because it may be turned for ever without coming to an end: *fig. 7.*

If in the endless, or perpetual screw,  $AB$ , whose threads take the teeth of the wheel  $CD$ , you take the distance of two threads, according to the length

of the axis A B ; or the distance of two teeth in the wheel C D, in the direction of the circumference ; and if a weight, W, act at the circumference of the wheel : then, if the power D be to the weight W, as that distance of the teeth or threads, to the length described by the power P in one revolution, the power and weight will be in æquilibrium ; because in one revolution of P, the wheel D C, with the weight W, has moved only the distance of one tooth.

**SCREW-TREE**, *Helicteres*, in botany. See the article **HELICTERES**.

**SCRIBE**, an officer among the Jews whose business was to write ; of which there were three kinds : the first and principal of which were the scribes of the law, whose office was to write and interpret scripture ; these were in great credit and esteem among the Jews, and had even the precedence of the priests and sacrificers, and their decisions were received with almost the same respect as the law of God itself : the second kind, properly called the scribes of the people, were a sort of magistrates : and the third were public notaries, or secretaries of the council ; which were the least considerable.

**SCRIBING**, in joinery, &c. is a term used when one side of a piece of stuff is to be fitted to another that is irregular. In order to make these join close all the way, they scribe it ; that is, they lay the piece to be scribed close to the other they intend to scribe it to, and opening their compasses to the widest distance these two pieces stand from each other, they bear the point of one of the legs against the side they intend to scribe to, and with the other point draw a line on the stuff to be scribed. Thus they form a line on the irregular piece parallel to the edge of the regular one ; and if the stuff be cut exactly to the line, when these pieces are put together they will seem a joint.

**SCRIPTURE**, an appellation given, by way of eminence, to the sacred and inspired writings of the Bible. See **BIBLE**, **CANONICAL**, &c.

**SCROPHULA**, the king's evil, in medicine, a hard glandulous tumour, usually of the same colour with the skin, seated principally in the sides of the neck, behind the ears, and under the chin : but though the principal seat of this disease is in the sides of the neck, scarcely any part of the body is exempted from it. The humour sometimes falls on the lungs, and brings on a pulmonary consumption ; and it is a dreadful circumstance, that this disorder is transmitted from parents to their children, by way of inheritance. As to the cure of this stubborn disease, says Dr. Mead, it is to be attempted by bleeding, purging, and such medicines as are most proper for correcting the viscidities, saltiness, and acrimony of the humours. Of cathartics, the best is dulcified mercury six times sublimed, which should be joined with rhubarb for children ; but to adults

it may be given alone, with a gentle purging draught some hours after it. The next to this in virtue is jalap : and our purging waters are also useful, as they scour the glands and open the body at the same time. In fine, a pill composed of mercury six times sublimed, and precipitated sulphur of antimony, each one grain ; of aloes three or four grains ; made up with the syrup of balsam, and taken every night, will be found serviceable, not only in this disease, but in others arising from viscid humours.

For correcting this pravity of blood and humours, the following powder may be taken twice a day, with three or four glasses of the less compound lime-water ; take of burnt sponge, one scruple ; of purified nitre, coralline, and white sugar, each ten grains ; mix them together : and if the patient happen to be emaciated, equal quantities of milk may be mixed with the water. The expressed juice of millepedes will also be of some service, on account of their diuretic quality. Issues likewise will be beneficial, to drain off the viscous humour ; and a change of aliment is often attended with good effects.

As to the patient's diet, which ought not to be neglected, let him feed on flesh of easy digestion, and abstain from all salt and smoke-dried meat and high-seasoned things ; and particularly from pork, hare, cheese, and in general from all things that are of hard digestion. Let him drink river-water, and that boiled ; but stagnating or snow-water never.

**SCROPHULARIA**, figwort, in botany, a genus of plants, whose flower is monopetalous and unequal ; the tube is large, globose, and inflated ; the limb is divided into five small parts, the two upper ones are large and erect, the side ones spread open, and the lower one is reflexed : the fruit is a roundish, acuminated, bilocular capsule, opening at the top, and containing many small seeds.

A species of this genus, which grows wild in divers parts of England, is said to be excellent in scrophulous disorders ; and is esteemed externally as a remedy for the piles ; it is generally made into an ointment for these purposes, and is also given internally in diet drinks.

**SCROTUM**, in anatomy, the capsule or bag in which the testicles are contained, and which hangs down below the penis. See the article **TESTICLE**.

**SCROTUM CORDIS**, the same with pericardium. See **PERICARDIUM**.

**SCROWLS**, or **SCROLLS**, in architecture, the same with volutes. See **VOLUTE**.

**SCRUPLE**, a weight equal to the third part of a dram, or to twenty grains. See the article **WEIGHTS**.

Among goldsmiths it is equal to twenty-four grains.

The scruples of the moon, &c. eclipsed, are the parts

parts of the moon's diameter immersed in the shadow, expressed in the same measure wherein the apparent diameter of the moon is expressed.

The *scruples* of half duration are an arch of the moon's orbit, which the center of the moon describes, from the beginning of an eclipse to its middle. *Scruples of immersion*, are an arch which the moon's center describes, from the beginning of the eclipse to its middle. And *scruples of emersion*, are an arch of the moon's orbit, described by her center from the time of the emersion of her limb to the end of the eclipse. See the article *ECLIPSE*.

**SCRUTINY**, a strict examination of the several votes taken at an election, in order to discover unqualified voters.

**SCULPTURE**, an art by which, in taking away, or adding to matter, all sorts of figures are formed by the hand, either in stone, wood, wax, or metal. In its full latitude it signifies both the art of working in *creux*, properly called engraving, and of working in *relievo*, which is more strictly called sculpture. See the articles *ENGRAVING* and *RELIEVO*.

The first works in sculpture were with clay, not only in making statues, but in forming models; and to this day, a sculptor never undertakes any thing considerable, without forming a model either in clay or wax. In making figures of these materials, they begin and finish their work with their hands, using only three or four pieces of wood, which are roundish at one end, and at the other flat, with a sort of claws and teeth, which are to smooth and scratch the work. For waxen models, to every pound of wax add half a pound of colophony; some add turpentine, and melt it together with oil of olives; more or less of the latter being used as they would have the matter harder or softer: some also add a little vermilion, to give it a colour: this is wrought and moulded with the fingers like clay. See the article *MOULDING*.

For sculpture in wood, which we properly call carving, the first thing required is to chuse wood proper for the work the sculptor is to perform. If it be any thing large, and requires a great deal of strength and solidity, the hardest and most durable wood is to be chosen; and for smaller works and ornaments, the softer wood is used; but it must be such, however, as is firm and close: for a large work, though it be only a single figure, it is better to make use of several pieces of wood, or bits of board, glued together, than of one whole piece, which is more liable to crack; for a thick piece of wood may not be dried to the heart, however it may appear on the outside.

Carving is performed with a great variety of chisels and other tools, for paring, scooping, rounding, &c. the several parts of the work.

In sculpture in marble and other stone, the first

thing to be done is to saw out a block of marble, of the bigness of the work to be performed; and this being done, the superfluities are to be taken off by a stubbed point and a heavy mallet; thus, bringing near the measures required, the sculptor reduces it still nearer with a finer tool, called a dog's tooth, it having two points, but one not so sharp as the other. After this he makes use of his gradine, which is a flat cutting tool, with three teeth; he then takes off with a smooth chisel, the scratches the gradine left on the marble, and uses it with dexterity and delicacy, to give softness and tenderness to his figure; till at length, taking rasps of different degrees of fineness, the work is gradually rendered fit for polishing.

To polish the work, the sculptor uses pumice-stone and smalt, then he goes over it with tripoli; and when he would give it more lustre, rubs it with leather and straw-ashes. There are several other tools used by sculptors, adapted to the different parts of the work, and the nature of the stone they make use of.

As the models of clay shrink when they grow dry, whenever sculptors undertake a considerable piece of work, they only use the model for making a mould of plaster or stucco, in which is formed a figure of the same matter, which thenceforth serves them for a model, and by which they adjust all their measures and proportions.

To proceed the more regularly, on the head of the model they place an immoveable circle, divided into degrees, with a moveable rule or index, fixed in the center of the circle, and divided also into equal parts: from the end of the rule hangs a line with a plummet, which serves to take all the points, to be transferred thence to the block of marble, from whose top hangs another plummet, like that of the model.

But there are some excellent sculptors, who disapprove of this method; urging, that the smallest motion of the model changes their measures, for which reason, they choose to take all their measures with the compasses.

**SCUM**, properly denotes the impurities which a liquor, by boiling, casts up to the surface. See the article *CLARIFICATION*.

The term *scum* is also used for what is more properly called the *scoria* of metals. See the article *SCORIA*.

In this last sense, the *scum* of lead is a sort of smalt, of various colours; and the *scum* of silver is what we commonly call *litharge*. See the article *LITHARGE*.

**SCURVY**, *Scorbutus*, in medicine, Dr. Mead observes, is the name given by medical writers, to a disease so various and different in appearance, that it does not seem to be one and the same distemper.

Boerhaave observes, that the scurvy chiefly affects the inhabitants of cold northern countries, especially those

those who live in marshy, low, fat, and moist soils, near stagnating waters, whether fresh or salt.

Those who live idle sedentary lives are most subject, chiefly in the winter time, to the attacks of this distemper; as also those feeding upon salted and smoke-dried flesh, or fish, sea-biscuit, stinking water, unfermented farinaceous vegetables, peas, beans, sharp, salt, old cheese; likewise those who are subject to melancholic, maniacal, hysteric, or hypochondriacal disorders; or those who have taken large quantities of the Peruvian bark without proper evacuations.

Dr. Pringle considers the scurvy as arising from a putrid cause only; and thinks that the species of that malady, said to be owing to an acid, is so far from being so, that it were to be wished this supposed species of scurvy had not been denominated of this distemper, and the more so, as he apprehends that in the countries most liable to the true scurvy, an acid is rarely to be blamed. He thinks, that if the acrimony of the fluids is great and sudden, a fever or flux will ensue; but if the accumulation is so slow, that the body grows habituated to the putrefaction, a scurvy prevails; this is the case in long voyages, occasioned by corrupted air and provisions, on board unventilated ships, in marshy countries from similar causes, and in a lesser degree in all northerly climates in most situations, from a want of due perspiration of what is putrid, and especially with the use of salted meats.

The scurvy, according to Sydenham, is known by a spontaneous weariness, a heaviness of the body, difficulty of breathing, especially after motion, rottenness of the gums, a stinking breath, frequent bleeding of the nose, difficulty of walking, sometimes a swelling and sometimes a falling away of the legs, in which there are always livid, plumbeous, yellow, or violet-coloured spots, and the colour of the face is generally of a pale tawney.

Boerhaave observes, that the first state of this disease begins with unusual laziness, spontaneous weariness; the patient loves to be in a sitting or lying posture; there is a pain in all the muscles, as if he was over tired, especially in the legs and loins; when he awakes in the morning, all his joints and muscles seem to be tired and bruised. In the second state, the gums swell, grow painful, hot, and itching, and bleed upon the least pressure: the roots of the teeth grow bare and loose; he feels pain in all the external and internal parts of the body, imitating distempers proper to the various parts.

In the third state, the gums at length grow putrid, with a cadaverous smell; when they are inflamed, blood distils from them, and a gangrene ensues; the loose teeth by degrees grow yellow, black, and rotten; the sublingual veins become varicose, and like rings; there are often fatal hæmorrhages, which break out from the external skin, without any appearance of a wound, from the lips, mouth, gums,

nose, lungs, stomach, liver, spleen, pancreas, intestines, womb, kidneys, &c. Obstinate ulcers arise, which no application will cure, and are apt to turn to a gangrene; they break out in all parts of the body, but especially the legs, and are attended with a stench; there is a kind of itch and dry scabs, with a dry and mild leprosy; the blood drawn from a vein is black and grumous, thick, and yet wants its due consistence in the fibrous part; the serum is salt, sharp, and abounding with a yellowish-green mucus on the surface: there are gnawing rending pains, quickly shifting from place to place, which grow more violent in the night, affecting all the joints, bones, and viscera. In the fourth state, there are fevers of various kinds which bring on an atrophy; sometimes diarrhoeas, dysenteries, or violent stranguries; as also faintings and mortal anxieties, a dropsy, consumption, convulsions, tremblings, a palsy, contractions, black spots, voiding of blood upwards and downwards, a putrefaction and consumption of the liver, spleen, pancreas, mesentery: and now the contagion spreads very quick.

From this account of the disease, it appears, continues the last-mentioned author, that one part of the blood is faulty in being too thick, and the other in being too thin, with a salt, alkaline, or acid acrimony; wherefore, to discover which of the three predominates, requires the utmost attention, and the most accurate enquiry: for, in the cure of this disease, that which is thick is to be attenuated; that which is stagnant, rendered moveable; and that which is coagulated is to be made fluid.

It ought to be laid down, says Hoffman, as a general rule, that the scurvy, the most virulent of all chronical distempers, is not to be treated with drastic but with the most mild and simple medicines: likewise the patient should change the air in which the disease was formed, and remove from unhealthy places, where the air is impure, vapid, and deprived of its due elasticity, cloudy, or impregnated with noxious exhalations, to places more salutary, where the air is more pure.

If his circumstances will not admit of travelling to Italy or France for a purer air, he should burn juniper-wood in his chimney, or throw amber on live coals. The patient should also use exercise, not indulge himself in much sleep, be temperate in his diet, and feed upon aliment of easy digestion.

Our author ventures to affirm, that mineral waters are an universal remedy for the scurvy; but the cure is still more certain, if an accurate regimen be observed, and the waters assisted by the repeated exhibition of proper antiscorbutic and balsamic medicines. When these cannot be had, pure light fountain-water, wherein hot iron has been extinguished, may be substituted in their room.

Besides mineral waters, nothing is more effectual in correcting a scorbutic acrimony, than a milk-diet, or whey, or whey impregnated with the juices

of antiscorbutic herbs, as scurvy-grafs and water-creffes.

Scurvy-grafs and all the species of garden and water-creffes, horse-radish, the roots of wild-radish, and mustard, are justly looked upon as antiscorbutics, for they induce a surprizing change both in the disordered fluids and solids. To these may be added the roots of gentian and succory, the leaves of scordium, carduus benedictus, wormwood, the lesser centaury, water-trefoil, or bucks-beans: balsamics and corroboratives, as juniper-berries, the tops of fir and pine-trees, winters-bark, cortex elutheriæ, and the Peruvian bark: the gums ammoniac, sagapenum, and galbanum; and the woods saffrafas, guaiacum, and aloes.

Medicines which allay the pains and spasms, are the fat of animals, cream, oil of sweet almonds, sperma ceti, castor, assa foetida, extracts of yarrow and chamomile, diascordium, saffron, earth-worms, elk-hoof, &c.

As to evacuations, bleeding should be used with the greatest caution; and none but the gentlest purges should be used, such as senna, rhubarb, or manna; also pills made after the manner of Becher, with depurated aloes, extract of rhubarb, bitter herbs, and temperate balsamic ingredients.

The diuretics should not be stronger than the decoction of the roots of parsley, celery, fennel, and asparagus.

The safest diaphoretics are dulcified spirit of nitre, flowers of sulphur, æthiops mineral, infusions in the manner of tea of Paul's betony, carduus benedictus, scordium, and elder-flowers, diaphoretic antimony, calcined and uncalcined hartshorn, amber, native cinnabar, cinnabar of antimony, and compound powder of crabs-claws: these things are adapted to a cold scurvy. But in the hot or alkaline, scurvy-grafs is too hot to be administered alone; wherefore it should be corrected with acids, such as wood-sorrel, the juices of citrons, oranges, barberries, and pomegranates; this should be accompanied with milk-meats, almond emulsions, barley-broths, water-gruel, chicken-broths, with endive, lettuce, sorrel, and creffes, at intervals.

When the scurvy proceeds from muriatic salts, which happens to those who live on smoked or high-salted fish or flesh, then whey, copiously drank, produces good effects; as also citrons, China-oranges, and ripe fruits; whereas spirituous and volatile antiscorbutics are generally detrimental.

Heister says, that when there is a continual salt taste in the mouth, lime-water drank morning and evening, is a high specific. The late bishop of Cloyne says, that if he may trust what trials he has been able to make, tar-water is good in the several sorts of scurvy, whether alkaline, acid, or muriatic; and that he believes it to be the only medicine that cures them all, without doing hurt in any. See the article TAR-WATER.

In a high degree of the scurvy mercurial salivation is looked upon by many as the only cure; which, by the vehement shock it gives the whole frame, and the sensible secretion it produces, may be thought to be more adequate to such an effect; but the disorder occasioned by that violent process, it is to be feared may never be got over.

SCURVY-GRASS, *Cochlearia*, in botany. See the article COCHLEARIA.

SCUTAGE was antiently a tax imposed on such as held lands, &c. by knight's service, towards furnishing the king's army: hence scutagio habendo was a writ that lay for the king, or other lord, against tenants holding by knight's service, to serve in person, or send a sufficient man in their room, or pay a certain sum, &c.

SCUTELLARIA, skull-cap, in botany, a genus of didynamious plants, the flower of which is monopetalous and ringent, the tube is very short and reflexed backwards, the chaps are long and compressed, the superior lip is concave and trifid; the middle segment being concave and emarginated with the side ones plane, and the lower lip broad and indented; there is no pericarpium but, the cup, which is monophyllous and helmet shaped, contains four roundish seeds which are covered up in it. This genus is the same as the cassida of Tournefort.

SCUTIFORME os, in anatomy, the chief bone of the knee, called also patella, mola, &c. See the article PATELLA.

SCUTIFORMIS CARTILAGO, in anatomy, one of the cartilages of the larynx, the broadest and biggest of them all, called also thyroides.

This cartilage is of a quadrangular figure, and stands in the interior part, where the pomum Adami makes its prominence, whence it is sometimes called the anterior cartilage. It is gibbous withoutside, and hollow within; sometimes double, chiefly in women, in whom it does not advance so far forward as in men.

SCUTTLES, in a ship, square holes cut in the deck, big enough to let in the body of a man, serving to let people down into any room below, upon occasion, or from one deck to another. They are generally before the main-mast, before the knight in the fore castle; in the gun room, to go down to the stern sheets; in the round-house, to go down into the captains cabin, when forced by the enemy in a fight aloft. There are also some smaller scuttles, which have gratings over them: and all of them have covers, that people may not fall down through them in the night.

Scuttle is also a name given those little windows and long holes which are cut out in cabins, to let in light.

SCYTALA, in mechanics, a term used by some writers, for a kind of radius, or spoke, standing out from the axis of a machine, as an handle or lever to turn it round and work it by.

SCYTALA LACONICA, a stratagem or device of the Lacedemonians, for the secret writing of letters to their correspondents, so that if they should chance to be intercepted, no body might be able to read them. To this end they had two wooden rollers or cylinders, perfectly alike and equal, one whereof was kept in the city, and another by the person to whom the letter was directed. For the letter, a skin of a very thin parchment was wrapped round the roller, and thereon was the matter written; which done it was taken off, and sent away to the party, who, upon putting it in the same manner upon his roller, found the lines and words in the very same disposition as when they were first written.

SEA, *Mare*, is frequently used for that vast tract of water encompassing the whole earth; but is more properly a part or division of these waters, and is better defined a less assemblage of water, which lieth before and washeth the coasts of some particular countries, from whence it is generally denominated, as the Irish sea, the Mediterranean sea, the Arabian sea, &c.

SEA-MEN, such as are reserved to serve the king, or other persons, at sea, who may not depart without license, &c. Seamen fighting, quarrelling, or making any disturbance, may be punished by the commissioners of the navy, with fine and imprisonment. Registered sea-men are exempted from serving in any parish office, &c. and are allowed bounty money besides their pay. By the law of merchants the seamen of a vessel are accountable to the master or commander, and the master to the owners, and the owners to the merchants, for damage sustained either by negligence or otherwise. Where a seaman is hired for a voyage, and he deserts it before it is ended, he shall lose his wages; and in case a ship be lost by a tempest, or in a storm, the sea-men lose their wages, as well as the owners their freight. See NAVALAFFAIRS.

SEA-HOLLY, *Eringium*, in botany. See ERYNGIUM.

SEA-ONION, See the article SCILLA.

SEA-WEED, *Fucus*. See the article FUCUS.

SEAL, *Sigillum*, a puncheon, or piece of metal, or other matter, usually either round or oval, whereon are engraven the arms, device, &c. of some prince, state, community; magistrate, or private person, often with a legend or subscription, the impression whereof in wax, serves to make acts, instruments, &c. authentic.

Before the time of William the conqueror, the makers of all deeds only subscribed their names, adding the sign of the cross, and a great number of witnesses; but that monarch and the nobility used seals with their arms on them, which example was afterwards followed by others. The colour of the wax wherewith this king's grants were sealed was usually green, to signify that the act continued fresh for ever, and of force.

A seal is absolutely necessary in respect of deeds, because the sealing of them makes persons parties thereto, and without being sealed they are void in law. It is held, that if a seal be broken off, it will render the deed void, and that where several are bound in a bond, the pulling off the seal of one vacates it as to all the rest.

The king's great seal is that whereby all patents, commissions, warrants, &c. coming from the king are sealed. The keeping hereof is in the hands of the lord high chancellor, who is hence denominated lord keeper. Indeed there is some difference between the lord chancellor and lord keeper, not in office, but in the manner of creation, the latter being made by the delivery of the great seal to him by the king, but the former having a patent. The king's privy seal is usually first set to grants that are to pass the great seal. See KEEPER.

SEAL is also used for the wax or lead and the impression thereon, affixed to the thing sealed.

SEALER, an officer in chancery appointed by the lord chancellor or keeper of the great seal, to seal the writs and instruments there made in his presence.

SEALING, in architecture, the fixing a piece of wood or iron in a wall with plaster, mortar, cement, lead, and other solid binding. For staples, hinges and joints, plaster is very proper.

SEALING-WAX. See the article WAX.

SEAM or SEME of *Corn*, is a measure of eight bushels.

SEAM of *Glass*, the quantity of 120 pounds or 24 stones, each five pounds weight. The seam of wood is an horse load.

SEAMS of a *ship*, are places where her planks meet and join together. There is also a kind of peculiar seam in the fowing of sails, which they call monk-seam; the other seam of a sail is the round seam, so called from its being round like the common seams.

SEARCHER. See the article ALNAGER.

Searcher is also an officer of the customs, whose business is to search and examine all ships outward bound, to see whether they have any prohibited or unaccustomed goods on board.

SEAR-CLOTH, or CERE-CLOTH, in surgery, a form of external remedy somewhat harder than an unguent, yet softer than an emplaster, though it is frequently used both for the one and the other. The sear-cloth is always supposed to have wax in its composition, which distinguishes and even denominates it. In effect, when a liniment or unguent has wax enough in it, it does not differ from a sear-cloth. Sear-cloths are a kind of substitutes to friction, and are sometimes used for other purposes; the best are compounded of resolvent drugs, as saffron, myrrh, and aloes, incorporated with wax and gums, as galbanum, gum ammoniac, and sagapenum, the whole tempered with wine.

SEASIN,

**SEASIN**, or **SEASING**, in a ship, the name of a rope by which the boat rides by the ship's side when in harbour, &c.

**SEASONS**, in cosmography, certain portions or quarters of the year, distinguished by the signs which the earth then enters, or by the meridian altitudes of the sun, consequent on which are different temperatures of the air, different works in tillage, &c. The year is divided into four seasons, spring, summer, autumn, and winter. The beginnings and endings of each whereof, see under its proper article, **SPRING**, &c.

**SEASONING of Timber**. See **TIMBER**.

**SEAT**, in astronomy. See **SHEAT**.

**SEAT**, in the manege, the posture or situation of a horseman upon the saddle.

**SEBESTEN**, *Cordia*, in botany, a genus of plants, whose flower is monopetalous and funnel-shaped; the tube is patulous, the length of the cup, and the top, is divided into four, five, or six, obtuse erect segments; it includes five subulated filaments topped with oblong antheræ: the fruit is a dry globose acuminate drupe, covered with the cup, containing a furrowed nut with four cells.

The fruit of a species belonging to this family of plants, are brought from Syria, and Egypt, and are used in medicine: they are moderately cooling and emollient, and help to obtund the acrimony of the humours; they are therefore recommended in defluxions, catarrhs, sharpness of urine, bilious fevers and costiveness; but in the present medical practice are not much in use.

**SECALE**, Rye in botany. See the article **RYE**.

**SECANT**, in geometry, is a line that cuts another, or divides it into two parts. See the article **LINE**.

In trigonometry, the secant denotes a right line drawn from the center of a circle which cutting the circumference, proceeds till it meets with a tangent to the same circle.

**SECOND**, in geometry, chronology, &c. the sixtieth part of a prime or minute, whether of a degree or of an hour: it is denoted by two small accents, thus ("). See **DEGREE**, **HOURLY**, **MINUTE**, &c.

**SECOND**, in music, one of the musical intervals; being only the difference between any found and the next nearest found, whether above or below it. See the article **INTERVAL**.

**SECONDARY**, in general, something that acts as second, or in subordination to another.

Secondary circles of the sphere, are circles passing through the poles of some great circle: thus the meridians and hour-circles are secondaries to the equinoctial.

There are also secondaries passing through the poles of the ecliptic, by means of which all stars are referred to the ecliptic. See the articles **ECLIP- TIC**, **LONGITUDE**, **SPHERE**, &c.

**SECRETARY**, an officer, who, by his master's orders, writes letters, dispatches, and other instruments, which he renders authentic by his signet.

Of these there are several kinds; as, 1. Secretaries of state, who are officers that have under their management and direction the most important affairs of the kingdom, and are obliged constantly to attend on the king: they receive and dispatch whatever comes to their hands, either from the crown, the church, the army, private grants, pardons, dispensations, &c. as likewise petitions to the sovereign, which, when read, are returned to them; all which they dispatch according to the king's direction.

2. Secretary of an embassy, a person attending an ambassador for writing dispatches relating to the negotiation.

There is a great difference between the secretary of an embassy, and the ambassador's secretary; the last being a domestic or menial of the ambassador, and the first, a servant or minister of the prince.

3. Secretary of war, an officer of the war-office, who has two chief clerks under him, the last of which is the secretary's messenger.

There are also secretaries in most of the other offices.

**CRETION**, *Secretion*, in the animal economy, the separation of some fluid mixed with the blood by means of the glands. See the article **GLAND**.

In the bodies of animals we observe a great number of juices of different natures, viz. the blood, lymph, saliva, stomach-liquor, intestinal juices, pancreatic juice, bile, urine, &c. and the blood is the general source of all. See the articles **BLOOD**, **LYMPH**, &c.

The manner in which this secretion is performed has been greatly enquired into for a century past; but as the exceeding minuteness of the organs whereby secretion is effected prevents any regular search, various authors have imagined various methods for explaining it.

The ancient physicians contented themselves only with asserting certain particular virtues or faculties inherent in the viscera, whereby they were determined to separate one liquor rather than another. Some of the moderns, full of the effects they have observed from fermentations, maintain, that there are ferments in the several parts, by the aid whereof certain kinds of particles mixed in the blood are separated therefrom, after the same manner as we see in must or new wine, from which, while fermenting, certain parts are detached in form of froth.

Others consider the glands as kinds of sieves, whose holes having different figures, will only let pass certain particles or molecules, whose figures resemble those of the holes; but the many inconveniences which both these suppositions have to grapple withal, made some naturalists have recourse to what

what is called imbibition: these maintain, that besides the different diameters of the pores, it is required that the several parts be already imbued or moistened with a liquor like to that they are to filtre.

This opinion Winslow adopted; and not satisfied with conjectural principles, applied himself to experiments, in order to investigate the manner wherein secretion is performed, and lays it down thus: It is well known that a piece of brown-paper (which is only an assemblage of small fibres compacted close to each other) having once imbibed oil or water, will never let any other liquor pass through it but of the same kind with what it is impregnated with; all others it stops. Now, in the secretory ducts of the glands we find a parallel structure, an assemblage of fine threads or filaments bound close together, much as in brown-paper, &c. only differently disposed; this plexus then having once imbibed a certain juice, will not let pass any of the liquors which arrive at the orifices of these ducts, but that which it had first imbibed: the cause of this phenomenon is referred to the attraction of cohesion, which is found stronger between the homogeneous than the heterogeneous parts of the same fluid.

As the blood, then, is not a homogeneous liquor, but a compound of an infinity of different parts or molecules, some oily, others mucilaginous, aqueous, saline, subtil, gross, &c. in its motion along the arteries of the gland, it becomes divided into all the little ramifications thereof, by which means its velocity is exceedingly abated, and the molecules are obliged to go off, one by one, through the narrow passage of the artery into the vein, and of consequence to pass over the orifice of the secretory ducts of the glands, whose down is already tinged with a juice of a certain nature: such of the molecules, therefore, as are found of the same nature with the juice they met with at the entrance of the secretory duct, join themselves to them, and entering the ducts, are driven on by others that follow them, and are at length driven into the excretory duct. But how these parts should have first imbibed the particular juices necessary for their respective secretions, is the question. Mr. Winslow thinks it probable that they had been imbued with the juices they were to filtrate at the first formation of the animal, or at the time when the solid parts were framed.

Kiel accounts for secretion from the joint consideration of the different diameters of the vessels, the different velocity of the blood, the different angles the ducts make with the arteries, and the different attraction of the various parts under all these different circumstances.

It is observed, that in this theory there is something arbitrary and conjectural; besides, that the reasoning is carried on to such a length, that in a thing, the principles whereof are so obscure, the

parts or organs so imperfectly known, and the whole process carried on out of sight, the mind cannot safely acquiesce in it.

Hales makes it evident from experiments, that the animal secretions are not made with the full force of the arterial blood, but more gradually and sparingly, so as to be carried forward in those very fine vessels by an alternate pulsive force of the arterial fluid, and attractive power of the fine secreting vessels, assisted also by constant vibrations; for the animal fluids and solids are in an incessant mutually-vibrating state.

In this manner, doubtless, the plentiful secretions are made into the stomach and guts, as also in the pancreas, mesenteric, salival, and other glands of the body; and thus also the perspiring matter is carried off, not by the more protrusive force of the arterial blood alone, but also by the warmth and mutual action of the fluids and solids. See PERSPIRATION, &c.

For the use, &c. of the animal secretions, see EXCRETION and EXCREMENT.

SECT, *Seeta*, a collective term, comprehending all such as follow the doctrines and opinions of some famous divine, philosopher, &c. See the articles HERESY and SCHISM.

The principal sects among the ancient philosophers were the Epicureans, Peripatetics, Academics, Stoics, Pyrrhonists, &c. See the article EPICUREANS.

Among the moderns, the Newtonians, Cartesians, &c. are the principal ones in Europe. See NEWTONIAN.

And the Calvinists, Lutherans, Papists, Anabaptists, Arians, Socinians, Arminians, &c. are the principal sects to be found among modern divines. See CALVINISTS, &c.

SECTION, in general, denotes a part of a divided thing, or the thing itself. Such, particularly, are the subdivisions of a chapter; called also paragraphs and articles: the mark of a section is §.

SECTION, in geometry, denotes a side or surface appearing of a body or figure cut by another; or the place where lines, planes, &c. cut each other.

The common section of two planes is always a right line; being the line supposed to be drawn on one plane by the section of the other, or by its entrance into it.

SECTION of a Building, in architecture, is the same with its profile; or a delineation of its heights and depths raised on a plane, as if the fabric was cut asunder to discover its inside.

Conic SECTIONS, in geometry. See the articles CONE and CONIC.

SECTOR, in geometry, is a part of a circle, comprehended between two radii and the arch; or it is a mixed triangle, formed by two radii and the arch of a circle. See the articles CIRCLE, ARCH, RADIUS, TRIANGLE, &c.

For the method of finding the area of a sector, as well as the segment of a circle, see the article SEGMENT.

SECTOR is also a mathematical instrument, of great use in finding the proportion between quantities of the same kind, as between lines and lines, surfaces and surfaces, &c. for which reason the French call it the compass of proportion.

The great advantage of the sector above common scales, &c. is, that it is adapted to all radii, and all scales. For, by the line of chords, sines, tangents, &c. on the sector, we have lines of chords, sines, tangents, &c. adapted to any radius between the length and breadth of the sector, when opened.

*Description of the SECTOR.* This instrument consists of two equal legs, or rules of brass, &c. riveted together, but so as to move easily on the rivet; on the faces of the instrument are placed several lines; the principal of which are the line of equal parts, line of chords, line of sines, line of tangents, line of secants, and line of polygons.

The line of equal parts, called also the line of lines, marked L, is a line divided into a 100 equal parts, and, where the length of the leg will admit it, each of these is subdivided into halves and quarters. It is found on each leg, on the same side, and the divisions numbered 1, 2, 3, 4, 5, &c. to 10, which is near the extremity of each leg. Note, in practice, 1 represents either 1, 10, 100, 1000, 10000, &c. as occasion requires, in which case, 2, represents 2, 20, 200, 2000, 20000, &c. and so of the rest. The line of chords, marked C on each leg, is divided after the usual manner, and numbered 10, 20, 30, &c. to 60. The line of sines, denoted on each leg by the letter S, is a line of natural sines, numbered 10, 20, 30, &c. to 90. The line of tangents, denoted on each leg by the letter T, is a line of natural tangents, numbered 10, 20, 30, &c. to 45. Besides which there is another little line of tangents on each leg, commencing at 45°, and extending to 79°, denoted by the letter t. Line of secants, denoted on each leg by the letter s, is a line of natural secants, numbered 10, 20, 30, &c. to 75, not commencing at the center of the instrument, but at some distance therefrom. The line of polygons, denoted by the letter P on each leg, is numbered 4, 5, 6, &c. to 12, which falls considerable short of the center of the instrument. See CHORD, SINE, &c.

*Use of the Line of equal Parts on the SECTOR.*

1. To divide a given line into any number of equal parts, suppose seven. Take the given line in your compasses, and setting one foot in a division of equal parts, that may be divided by seven, for example, 70, whose seventh part is 10, open the sector till the other point falls exactly on 70, in the same line on the other leg. In this disposition, applying one part of the compasses to 10, in the same line, shut them till the other fall in 10, in the same

line, on the other leg, and this opening will be the seventh part of the given line. Note, if the line to be divided be too long to be applied to the legs of the sector, divide only one half, or one fourth, by 7, and the double or quadruple thereof will be the seventh part of the whole.

2. To measure the lines of the perimeter of a polygon, one of which contains a given number of equal parts. Take the given line in your compasses, and set it parallel, upon the line of equal parts, to the number on each leg expressing its length. The sector remaining thus, set off the length of each of the other lines parallel to the former, and the numbers each of them falls on, will express their lengths.

3. A right line being given, and the number of parts it contains, suppose 120, to take from it a shorter line, containing any number of the same parts, suppose 25. Take the given line in your compasses, open the sector till the two feet fall on 120 on each leg; then will the distance between 25 on one leg, and the same number on the other, give the line required.

4. To multiply by the line of equal parts on the sector. Take the lateral distance from the center of the line to the given multiplicator; open the sector till you fit that lateral distance to the parallel of 1 and 1, or 10 and 10, and keep the sector in that disposition; then take in the compasses the parallel distance of the multiplicand, which distance, measured laterally on the same line, will give the product required. Thus, suppose it were required to find the product of 8, multiply by 4: take the lateral distance from the center of the line to 4 in your compasses, i. e. place one foot of the compasses in the beginning of the divisions, and extend the other along the line to 4. Open the sector till you fit this lateral distance to the parallel of 1 and 1, or 10 and 10. Then take the parallel distance of 8, the multiplicand; i. e. extend the compasses from 8, in this line, on one leg, to 8 in the same line on the other, and that extent, measured laterally, will give the product required.

5. To divide by the line of equal parts on the sector. Extend the compasses laterally from the beginning of the line to 1, and open the sector till you fit that extent to the parallel of the divisor; then take the parallel distance of the dividend, which extent, measured in a lateral direction, will give the quotient required. Thus suppose it was required to divide 36 by 4; extend the compasses laterally, the beginning of the line to 1, and fit to that extent the parallel of 4, the divisor; then extend the compasses parallel, from 36 on one leg to 36 on the other, and that extent, measured laterally, will give 9, the quotient required.

6. To work any proportion by the sector. Take the second term lateral, and, opening the sector, apply that extent parallel in the first term,

E c

and

and stay the sector in that position; then take the parallel distance of the third term, which extent, measured laterally, gives the fourth term required. This is so easy, from what has already been said, that it needs no example.

*The Use of the Line of Chords on the SECTOR.*

1. To open the sector so as the two lines of chords may make an angle or number of degrees, suppose 40. Take the distance from the joint to 40, the number of the degrees proposed, on the line of chords; open the sector till the distance from 60 to 60, on each leg, be equal to the given distance of 40; then with the two lines on the sector form an angle of 40 degrees, as was required.

2. The sector being opened, to find the degrees of its aperture. Take the extent from 60 to 60, and lay it off on the line of chords from the center; the number whereon it terminates will shew the degrees, &c. required.

3. To lay off any number of degrees upon the circumference of a circle. Open the sector till the distance between 60 and 60 be equal to the radius of the given circle; then take the parallel extent of the chord of the number of degrees on each leg of the sector, and lay it off on the circumferences of the given circle. Hence any regular polygon may be easily inscribed in a given circle.

*Use of the Line of Polygons on the SECTOR.*

1. To inscribe a regular polygon in a given circle. Take the semi-diameter of the given circle in the compasses, and adjust it to the number 6, on the line of polygons, on each leg of the sector: then, the sector remaining thus opened, take the distance of the two equal numbers, expressing the number of sides the polygon is to have; e. gr. the distance from 5 to 5 for a pentagon; from 7 to 7 for a heptagon, &c. These distances carried about the circumference of the circle, will divide it into so many equal parts.

2. To describe a regular polygon, e. gr. a pentagon, on a given right line. Take the length of the line in the compasses, and apply it to the extent of the number 5, 5, on the lines of polygons. The sector thus opened, upon the same lines, take the extent, from 6 to 6; this will be the semi-diameter of the circle the polygon is to be inscribed in. If, then, with this distance, from the ends of the given line, you describe two arches of a circle, their intersection will be the center of the circle.

3. On a right line, to describe an isosceles triangle, having the angle at the base double that at the vertex. Open the sector, till the ends of the given line fall on 10 and 10 on each leg; then take the distance from 6 to 6. This will be the length of the two equal sides of the triangle.

*Use of the Lines of Sines, Tangents, and Secants, on the SECTOR.*

By the several lines disposed in the sector, we have scales to several radiuses; so that having a

length or radius given, not exceeding the length of the sector when opened, we find the chord, sine, &c. thereto, e. gr. Suppose the chord, sine, or tangent, of 10 degrees, to a radius of 3 inches, required; make 3 inches the aperture, between 60 and 60, on the lines of chords of the two legs; then will the same extent reach from 45 to 45 on the line of tangents, and from 90 to 90 on the line of the sines on the other side; so that to whatever radius the line of chords is set, to the same are all the others set. In this disposition, therefore, if the aperture between 10 and 10, on the lines of chords, be taken with the compasses, it will give the chord of 10 degrees. If the aperture of 10 and 10 be in like manner taken on the lines of sines, it will be the sine of 10 degrees. Lastly, if the aperture of 10 and 10 be in like manner taken on the lines of tangents, it gives the tangent of 10 degrees.

If the chord, or tangent, of 70 degrees was required; for the chord, the aperture of half the arch, viz. 35, must be taken, as before; which distance, repeated twice, gives the chord of 70 degrees. To find the tangent of 70 degrees to the same radius, the small line of tangents must be used, the other only reaching to 45: making, therefore, 3 inches the aperture between 45 and 45 on the small line; the extent between 70 and 70 degrees on the same, will be the tangent of 70 degrees to 3 inches radius.

To find the secant of an arch, make the given radius the aperture between 0 and 0 on the line of secants: then will the aperture of 10 and 10, or 70 and 70, on the said lines, give the tangent of 10°, or 70°.

If the converse of any of these things were required; that is, if the radius be required, to which a given line is the sine, tangent, or secant, it is but making the given line, if a chord, the aperture on the line of chords, between 10 and 10, and then the sector will stand at the radius required; that is, the aperture between 60 and 60, on the said line, is the radius. If the given line were a sine, tangent, or secant, it is but making it the aperture of the given number of degrees; then will the distance of 90 and 90 on the lines, of 45 and 45 on the tangents, of 0 and 0 on the secants, be the radius.

SECULAR, something that is temporal, in which sense the word stands opposed to ecclesiastical: thus we say, secular power, secular jurisdiction, &c.

Secular is more peculiarly used for a person who lives at liberty in the world, not shut up in a monastery, nor bound by vows, or subjected to the particular rules of any religious community; in which sense it stands opposed to regular. The Romish clergy is divided into secular and regular.

SECULAR GAMES, *Ludi Seculares*, in antiquity, solemn games held among the Romans once in an age. These games lasted three days and as many nights,

nights, during which time sacrifices were performed, theatrical shews exhibited, with combats, sports, &c. in the circus. The occasion of these games, according to Valerius Maximus, was to stop the progress of a plague. The first who had them celebrated at Rome was Valerius Publicola, the first consul created after the expulsion of the kings. The ceremonies to be observed therein were found prescribed in one of the books of the Sibyls. At the time of the celebration of the secular games, heralds were sent throughout all the empire, to intimate that every one might come and see those solemnities which he never yet had seen, nor was ever to see again. Authors are not agreed as to the number of years wherein these games were returned, partly because the quantity of an age or seculum, among the antients, is not known, and partly on other accounts; some will have it that they were held every hundred years, and that the seculum or age was our century.

**SECULAR POEM**, *Carmen seculare*, a poem sung or rehearsed at the secular games, of which kind we have a very fine piece among the works of Horace, being a sapphic ode at the end of his epodes.

**SECULARIZATION**, the act of converting a regular person, place, or benefice into a secular one.

**SECUNDINES**, *Secundinæ*, after birth, in anatomy, the several coats or membranes wherein the foetus is wrapped up in the mother's womb, as the chorion and amnios, with the placenta, &c. See the articles **CHORION**, **AMNIOS**, **PLACENTA**, **ALANTOIS**, &c.

**SEDANTIA**, sedative medicines, in pharmacy, such medicines as are possessed of a power not only of composing, checking, and allaying the exorbitant and irregular motions of the solids and fluids, but also of alleviating and resolving the painful spasmodic structures of the parts.

As the effect of these medicines are very extensive, we may justly include in their number paretorics, which not only relax and gently soothe the rigid fibres, but also obtund the acrimony of the juices; anodynes, which alleviate the violence of racking pains; antispasmodics, which mitigate and remove the spasmodic structures of the parts; antiepileptics, which check convulsive motions; hypnotics, which procure sleep; and narcotics, which induce a considerable stupor of the senses and torpor of all the motions of the body. See **PAREGORIC**, **ANODYNE**, **ANTISPASMODIC**, &c.

**SE DEFENDENDO**, in law, a plea used for him that is charged with the death of another, by alleging that he was under a necessity of doing what he did in his own defence; as that the other assaulted him in such a manner, that if he had not done what he did, he must have been in hazard of his own life. But here the danger must appear so

great, as to be inevitable. Any person in his just defence may kill others for the safety of his life; though if malice be coloured under a pretence of necessity, or one kill another before he is under a necessity of so doing, the same may be either murder or manslaughter by our law. See the articles **MURDER** and **MANSLAUGHTER**.

Where two persons suddenly fall out, and one of them, being attacked, flies to the wall, or any unpassable place, as far as he can, in order to save his life, but being still pursued, kills the person that attacked him, this killing, as well as others in the like cases, is *se defendendo*. In *se defendendo*, though the affair justifies the killing to have been in his own defence, he is nevertheless obliged to sue out his pardon from the lord chancellor, which of course is granted him, but yet his goods and chattels become forfeited to the king. It is said, however, that upon the special matter found, he may be dismissed without any forfeiture, &c.

**SEDIMENT**, the settlement or dregs of any thing, or that gross heavy part of a fluid body which, upon resting, sinks to the bottom of the vessel.

**SEDR**, or **SEPRE**, the high priest of the sect of Ali among the Persians.

**SEDUM**, house-leek, in botany, a genus of plants, whose flower consists of five plane lanceolated pointed petals, with five nectaria, each being a small emarginated scale and inserted on the back of the germen; the fruit consists of five erecto-patent, acuminate, compressed capsules, emarginated at the base, and opening from top to bottom; the seeds are numerous and small. This genus includes the orpine and stone-crop.

The common house-leek grows on the tops of old walls and houses, it is evergreen, flowers in July, and the stalk withers in autumn. This plant is said to be cooling, cleansing, and astringent; and some give four ounces of the juice to cure intermittent fevers, when there is no cold fit; and the leaves are sometimes used externally to cure the piles, but it must be done with caution.

**SEED**, *Semen*, in physiology, a substance prepared by nature, for the reproduction and conservation of the species, both in animals and plants. See **GENERATION**.

The seed of animals, and particularly of mankind, is a whitish fluid, secreted from the blood in the testes. See **TESTES**.

It is the thickest and most elaborated of all the humours in the human body; and by a chemical analysis, is found to consist almost entirely of oil and volatile salts blended with a little phlegm.

The seminal liquor, however, such as emitted for use, is a mixture of the true semen with the liquors of the prostate, and other glands of the penis; all which, in the act of coition, are poured at the same time into the common canal of the urethra, either from the glands where they are secreted, or the

the reservoirs where they are kept; and being there blended together, are injected into the uterus. See CONCEPTION, FORTUS, &c.

*SEED of Vegetables*, is their last product whereby the species are propagated; being frequently the fruit of a plant, but sometimes only a part included in the fruit.

Every seed consists of an embryo-plant, called *plantula-feminalis*, with its covers.

The embryo, which is the whole future plant in miniature, is called the germ or bud; and is rooted in the cotyledon or placenta, which makes its involucre or cover. The cotyledon is always double; and in the middle, and common center of the two, is a point or speck, viz. the embryo plantule, which being acted on by the warmth of the sun and of the earth, begins to protude its radicle or root downwards, and its bud upwards; and as the requisite heat continues, it draws nourishment by the root, and so continues to unfold itself and grow.

The two placentalæ or cotyledons of a seed, are, as it were, a case to the little embryo-plant, covering it up, and sheltering it from injuries, and feeding it from their own proper substance; which the plantule receives and draws to itself by an infinite number of little filaments, which it sends in the body of the placenta.

The cotyledons, for the most part, abound with a balsam disposed in proper cells; and this seems to be oil brought to its greatest perfection, while it remains tumid, and lodged in these repositories: one part of the composition of this balsam is oily and tenacious, and serves to defend the embryo from any extraneous moisture; and, by its viscosity, to entangle and retain the fine, pure, volatile spirit, which is the ultimate production of the plant. This oil is never observed to enter into the vessels of the embryo, which are too fine to admit so thick a fluid. The spirit, however, being quickened by an active power, may possibly breathe a vital principle into the juices that nourish the embryo, and stamp upon it the character that distinguishes the family; after which every thing is changed into the proper nature of that particular plant.

Now, when the seed is committed to the earth, the placenta still adheres to the embryo for some time, and guards it from the access of noxious colds, &c. and even prepares and purifies the cruder juice the young plant is to receive from the earth, by straining it through its own body. This it continues to do till the embryo-plant, being a little enured to its new element, and its root tolerably fixed in the ground, and fit to absorb the juice thereof, it then perishes, and the plant may be said to be delivered; so that nature observes the same method in plants contained in fruits, as in animals in the mother's womb.

Many sorts of seeds will continue good for several years, and retain their vegetative faculty; whereas

others will not grow after they are one year old; this difference is in a great measure owing to their abounding more or less with oil, as also to the nature of the oil, and the texture of the outward covering.

All seeds require some share of fresh air, to keep the germen in a healthy state; and where the air is absolutely excluded, the vegetative quality of the seeds will soon be lost. But seeds will be longest of all preserved in the earth, provided they are buried so deep as to be beyond the influence of the sun and showers; since they have been found to lie thus buried twenty or thirty years, and yet vegetate as well as new seeds. How the vegetative life is so long preserved, by burying them so deep in the ground, is very difficult to explain; but as the fact is very well known, it accounts for the production of plants out of earth, taken from the bottom of vaults, houses, &c.

In the common method of sowing seeds, there are many kinds which require to be sown soon after they are ripe; and there are many others which lie in the ground a year, sometimes two or three years, before the plants come up: hence when seeds brought from distant countries are sown, the ground should not be disturbed, at least for two years, for fear of destroying the young plants.

As to the method of preserving seeds, the dry kinds are best kept in their pods or outer coverings; but the seeds of all soft fruits, as cucumbers, melons, &c. must be cleansed from the pulp and mucilage which surround them, otherwise the rotting of these parts will corrupt the seeds.

When seeds are gathered, it should always be done in dry weather; and then they should be hung up in bags in a dry room, so as not to deprive them of air.

Dispensatory writers divide the seeds used in medicine into four classes: 1. The four greater hot seeds, viz. of aniseed, fennel, caraway, and cummin. 2. The four lesser hot seeds, viz. of bishops-weed, stone-parsley, smallage, and wild-carrot. 3. The four greater cold seeds, viz. cucumber, cucurbit, citruls, and melons. 4. The four lesser cold seeds, viz. endive, scarbola, lettuce, and purslain. See ANISE, FENNEL, &c.

But besides these, there are many other seeds prescribed for their medicinal virtues; as those of coriander, dill, thlaspi, mustard, linseed, scœnugreek, carthamus, navew, ricinus, sorrel, psyllium, stavesacre, &c. See the articles CORIANDER, DILL, &c.

*Change of SEED.* Seed-wheat should be brought from the crop on a strong clay-land, whatever kind of land it is to be sowed upon. A white clay is a good change for a red clay, and a red clay for a white; but whatever the land be, from which the seed is taken, it may be infected, if that be not changed there the preceding year; and then there may

may be danger, though it be had from ever so proper a land. It is a rule among the farmers, never to buy seed-wheat from a sandy soil; they express their dislike of this by the coarse rhyme, Sand is a change for no land. See the article CHANGE.

SEEDLINGS, among gardeners, are young plants which have not been transplanted from the beds where they were sown: it is also a term used to distinguish plants raised of the seeds from those of the same kinds which have been propagated by layers, cuttings, &c.

SEEDY, in the brandy-trade, a term used by the dealers, to denote a fault that is found in several parcels of French brandy, which renders them unsaleable. The French suppose that these brandies obtain the flavour which they express by this name, from weeds that grow among the vines from whence the wine of which this brandy is made was pressed. However it be, the thing is evident, and the taste not of any one kind, some tasting strongly of aniseed, some of caraway-seed, and some others of the strong flavoured seeds of plants. The business of rectification of spirits, Dr. Shaw observes, is very little understood abroad, though much practised with us; and there is no doubt but that the same means which we use to rectify malt spirits, would also serve to purify these brandies. See the article RECTIFICATION.

SEEING, the act of perceiving objects by the organ of sight; or it is the sense we have of external objects by means of the eye. See the article SIGHT.

SEELING, in the manege, a horse is said to feel when he begins to have white eye-brows, that is, when there grows on that part about the breadth of a farthing of white hairs, mixed with those of his natural colour, which is a mark of old age. It is said, that a horse never feels till he is fourteen years old, and always does before he is sixteen years. The light, sorrel, and black, sooner feel than any other. Horse-jockeys usually pull out those hairs with pincers; but if there be so many, that it cannot be done without making the horse look bald and ugly, then they colour their eye-brows, that they may not appear old.

SEELING, at sea, is used in the same sense nearly with heeling: when a ship lies down constantly, or steadily on one side, the seamen say, she heels; and they call it feeling when the tumbles violently and suddenly, by reason of the sea forsaking her, as they call it, that is, the waves leaving her for a time in a bowling sea. When a ship thus tumbles to leeward, they call it lee-feel; and in this there is not much danger, even in a storm, because the sea will easily right her up again; but if she rows or feels to windward, there is fear of her coming over too short or suddenly, and so having the sea break right into her, be either foundered, or have some of her upper works carried away.

SEGMENT of a Circle, in geometry, that part of the circle contained between a chord and an arch of the same circle. See CIRCLE, ARCH, and CHORD.

SEGMENT of a Sphere, is a part of a sphere terminated by a portion of its surface, and a plane which cuts it off, passing somewhere out of the center; being more properly called the section of a sphere.

The base of such a segment, it is evident, is always a circle for finding the solid contents of the segment of a sphere. See the article FRUSTUM.

SEGMENT is sometimes also extended to the parts of the ellipses, and other curvilinear figures.

SEGMOIDAL Valves, in anatomy, little valves of the pulmonary artery, thus called from their resembling segments of circles, but more usually called semi-lunar valves.

SEGUIERIA, in botany, a genus of plants, whose flower hath no corolla, but consists in a pentaphyllous patent cup, which is coloured and persistent, and contains a great number of capillary patent filaments, terminated with oblong antheræ; the fruit is an oblong capsule, having one cell, and containing a smooth seed of the same form.

SEIGNIORY, *Dominium*, in our law, is used for a manor or lordship of a seigneur, or lord of the fee or manor.

SEIGNORAGE, signifies the right, or due belonging to a seigneur, or lord; but it is particularly used for a duty belonging to the prince, for the coining of money; called also coinage, which, under our ancient kings, was five shillings for every pound of gold brought in the mass to be coined, and a shilling for every pound weight of silver. At present the king claims no seignorage at all, but the subject has his money coined at the public expence; nor has the king any advantage therefrom, but what he has from the alloy.

SEISIN, in law, signifies possession. See the article POSSESSION.

In this sense we say, premier seisin, for the first possession, &c. See PREMIER.

Seisin is divided into that in deed or in fact, and that in law; a seisin in deed is where a possession is actually taken; but a seisin in law is, where lands descend, and the party has not entered thereon; or in other words, it is, where a person has a right to lands, &c. and is by wrong disseised of them.

SEIZE, SEAZE, or SEASE, in the sea-language, is to make fast, or bind, particularly to fasten two ropes together, with rope-yarn. The seizing of a boat is a rope tied to a ring, or little chain in the foreship of the boat, by which means it is fastened to the side of the ship.

SEIZURE, in commerce, an arrest of some merchandize, moveable, or other matter, either in consequence of some law, or of some express order of the sovereign. Contraband goods, those fraudu-

lently entered, or landed without entering at all, or at wrong places, are subject to seizure. In seizures, among us, one half goes to the informer, and the other half to the king.

**SELAGO**, in botany, a plant which grows naturally at the Cape of Good Hope; it has slender ligneous stalks, which grow seven or eight feet in length, sending out many slender branches, which are furnished with short linear hairy leaves, which grow in clusters; the flowers are produced in umbels at the top of the stalks, the general umbel being composed of a multiplicity of small umbels; they are monopetalous and of a white colour, they have no pericarpium; but the seed, which is single and roundish, is involved in the corolla.

**SELAGO**, is also a name by which Dillenius calls the lycopodium of Linnæus.

**SELENDERS**, in the manege, are chaps, or mangy fores, in the bending of a horse's hough, as the malanders are in the knees. See **MALANDERS**.

**SELENOGRAPHY**, a branch of cosmography, which describes the moon and all the parts and appearances thereof, as geography does those of the earth. See the article **MOON**.

**SELEUCIDÆ**, in chronology. *Æra* of the Seleucidæ, or the Syro-Macedonian æra, is a computation of time, commencing from the establishment of the Seleucidæ; a race of Greek kings, who reigned as successors of Alexander the Great, in Syria, as the Ptolemies did in Egypt. This æra we find expressed in the book of the Maccabees, and on a great number of Greek medals, struck by the cities of Syria, &c. The rabbins call it the æra of contracts; and the Arabs, therik dilkarnain, that is, the æra of the two horns. According to the best accounts, the first year of this æra falls in the year 311 before Christ, being twelve years after Alexander's death.

**SELINUM**, in botany, a genus of umbelliferous plants, the general corolla whereof is uniform; the flowers consist each of five unequal, inflexed, heart-shaped petals, with five capillary filaments, topped with roundish antheræ; there is no pericarpium, but the fruit is of an elliptic, oblong, compressed, and plane figure, channeled on each side, in the middle, and parting in two seeds, which are edged with membranes on their side.

**SELL**, in building, is of two kinds, viz. ground-sell, which denotes the lowest piece of timber in a timber-building, and that on which the whole superstructure is raised: and the window-sell, called also window-soil, is the bottom piece in a window frame.

**SEMETs**, **SUMMETs**, or **SUMMITs**, in botany, the same with the antheræ. See the article **ANTHERÆ**.

**SEMI**, a word borrowed from the Latin, signify-

ing *half*, but only used in composition with other words, as in the following articles.

**SEMI-ARIANS**, in church-history, a branch of the antient Arians, consisting of such as in appearance condemned the errors of that heresiarch, but yet acquiesced in some of the principles thereof, only palliating and concealing them under softer and more moderate terms. They would not allow, with the catholics, that the Son was homoousios, *i. e.* of the same substance, but homoiousios, *i. e.* of a like substance, with the Father; and thus, though, in expression, they differed from the orthodoxy in a single letter only, yet, in effect, they denied the divinity of Jesus Christ, and placed him in the rank of creatures.

**SEMI-CIRCLE**, in geometry, half a circle, or that figure comprehended between the diameter of a circle and half the circumference.

**SEMI-CIRCLE** is also an instrument used in surveying, otherwise called graphometer.

**SEMI-COLON**, in grammar, one of the points or stops used to distinguish the several members of sentences from each other. See **PUNCTUATION**.

The mark or character of the semicolon is (;) and has its name as being somewhat of less effect than a colon, or as demanding a shorter pause.

**SEMI-CUBICAL Parabola**, in the higher geometry, a curve of the second order, wherein the cubes of the ordinates are as the squares of the abscissæ. Its equation is  $axx = y^3$ .

**SEMI-CUPIUM**, in medicine, an half bath wherein the patient is only placed up to the navel.

**SEMI-DIAMETER**, half the diameter, or a right line drawn from the center of a circle, or sphere, to its circumference; being the same with what is otherwise called the radius. See **RADIUS**.

The distances, diameters, &c. of the heavenly bodies, are usually estimated, by astronomers, in semi-diameters of the earth; and the distances of the secondary planets, from their respective primary ones, by semi-diameters of the body of the primary planet. See **DISTANCE**, **DIAMETER**, and **PLANET**.

**SEMI-DOUBLE**, in the Romish breviary, a term applied to such offices and festivals as are celebrated with less solemnity than the double ones, but yet with more than the single ones.

**SEMI-FISTULAR FLOWERS**, among botanists, are such whose upper part resembles a pipe cut off obliquely, as in the aristolochia.

**SEMI-FLOSCULOUS**, in botany, a term used to express the flowers of a certain class of plants, of which the dandelion, hawk-weed, and the like, are kinds.

These semifloscules are petals, hollow in their lower part, but in their upper flat, and continued in the shape of a tongue. See **FLOSCULOUS**.

**SEMI-**

**SEMI-LUNAR VALVES**, in anatomy, are three small valves, or membranes, of a semi-lunar figure, placed in the orifice of the pulmonary artery, to prevent the relapse of the blood into the heart at the time of its dilatation. See the article **HEART**.

**SEMI-MEMBRANOSUS**, in anatomy, a long thin muscle, partly tendinous; situated on the backside of the thigh, a little towards the inside; being one of the five flexors of the tibia. It arises from the tubercle of the ischium.

**SEMI-ORDINATE**, in conics, &c. the half of an ordinate. See the article **ORDINATE**.

**SEMI-PARABOLA**, in geometry, a curve defined by the equation  $ax^{m-1} = y^m$ ; as  $ax^2 = y^3$ , and  $ax^3 = y^4$ . See the article **PARABOLA**.

In semi-parabolas,  $y^m : v^m :: ax^{m-1} : az^{m-1} = x^{m-1} : z^{m-1}$ ; or, the powers of the semi-ordinates are, as the powers of the semi-abscisses, one degree lower; for instance, in cubical semi-parabolas, the cubes of the ordinates are as the squares of the abscisses; that is,  $y^3 : v^3 :: x^2 : z^2$ .

**SEMI-PELAGIANS**, in church history, a branch of the Pelagians; so called, because they pretended to keep a medium between the Pelagians and the orthodox. See **PELAGIANS**.

**SEMI-TONE**, in music, one of the degrees or concinnous intervals of concords.

The ratio of the semi-tone is 15 : 16. See the article **TONE**.

**SEMINAL**, *Seminalis*, in anatomy and medicine, something belonging to the semen, or seed. See **SEED**.

**SEMINARY**, a kind of college, or school, where youth are instructed in the ceremonies, &c. of the sacred ministry, of which there are many abroad; it being ordained, by the council of Trent, that there be a seminary belonging to each cathedral, under the direction of the bishop.

**SEMINARY**, in gardening, denotes the seed plot, or place allotted for raising plants from seed, and keeping them till they are fit to be removed into the garden or nursery.

When the seminary is intended for trees, it must be large, and of a soil adapted to the generality of the trees intended to be raised in it: but that which is most in use is for the supply of the flower garden, and is the place where flowers are to be raised from their seeds, to procure varieties; or, as the florists express it, new flowers; as also for the sowing all the biennial plants, to succeed those which decay in the flower-garden.

The seminary should always be situated at some distance from the house, and be walled or paled round, and kept under lock and key, to keep out dogs, &c. and to prevent a great deal of damage that is frequently done by those who are not acquainted with gardening, before they are aware of it. The several directions for the management of the

seminary, are to be seen under the names of the several plants intended to be raised in it.

**SEMINATION**, in natural history, denotes the manner, or act, of shedding and dispersing the seeds of plants, which is effected several ways. Some are heavy enough to fall directly to the ground; others are furnished with a pappus, or down, that they may, by means thereof, be dispersed by the wind; and others, again, are contained in elastic capsules, which bursting open with considerable force, dart or throw out the seeds to different distances.

**SEMINERVOSUS**, in anatomy, one of the flexor muscles of the leg, which arises from the ischium, and is inserted into the upper part of the tibia.

**SEMISS**, in Roman antiquity, the half of an as. See the article **AS**.

**SEMISPINALIS**, or **SEMISPINOSUS**, in anatomy, one of the extensor muscles of the back and loins, has its origin from the os sacrum and vertebræ of the loins, and its termination at the upper vertebræ of the thorax, especially at the spinose apophyses; it coheres very firmly to the longissimus dorsi and sacro-lumbaris, the other two extensors of the back and loins.

**SEMITA LUMINOSA**, a name given to a lucid tract in the heavens, which may be seen about six o'clock at night, a little before the vernal equinox, extending from the western edge of the horizon up towards the pleiades.

Cassini thinks this phenomenon arises from a vast number of small planets encompassing the sun, which give this light from reflection.

**SEMPERVIVUM**, in botany, a genus of plants, whose corolla consists of six or twelve oblong, lanceolated, acute, concave petals, a little larger than the cup: the fruit consists of twelve oblong, compressed, short capsules, placed in an orbicular order, pointed outwards, opening within, and containing a number of roundish small seeds.

This genus comprehends the African tree-house-leek, a variety of which, with striped leaves, is a very beautiful plant; it is propagated by cuttings in the summer months, and requires a hot-house in winter for its preservation; but being very succulent, it should have but little water given, lest it should rot, which it is apt to do when it has too much moisture.

**SENA**, or **SENNA**, in botany. See the article **SENNA**.

**SENATE**, *Senatus*, in general, is an assembly or council of senators; that is, of the principal inhabitants of a state, who have a share in the government.

**SENATOR**, in general, denotes a member of some senate.

**SENECA**, or **SENEGA**. See **SENEGA**.

SE-

**SENECIO**, groundsel, in botany, a genus of plants, whose flower is compound and radiated; the corollulæ which form the disc are numerous, tubulated, and hermaphrodite; the female florets which form the rays are ligulated, oblong, and tridentated: there is no pericarpium; but the seeds, which are crowned with down, are contained in the cup, and placed on a plane naked receptacle.

This genus includes the *Jacobæa* of Tournelort. The common groundsel is emollient and resolvent, and taken in a strong infusion, proves emetic: it is prescribed in small doses in the jaundice, dropsy, and hæmorrhages; and externally, it is used in ointments for disorders of the skin.

**SENEGA**, *Seneca*, or *Seneka*, rattle-snake-root, in the materia medica. See the article **POLYGALA**.

**SENGREEN**, in botany. See the article **SEMPERVIVUM**.

**SENNA**, or **SENA**, in botany, an annual plant, which grows naturally in Egypt; it rises with an upright branching stalk, about a foot high; furnished with winged leaves, composed of four pair of small lanceolated folioli, ending in acute points; the flowers are produced in loose bunches at the top of the stalk; they are of a yellow colour, and composed of five roundish concave petals, with ten stamina, surrounding the style; when the flower is decayed, a roundish, incurved, compressed pod succeeds, having two cells, divided by an intermediate partition, each containing one or two seeds.

This plant is comprehended by Linnæus among the cassias. See the article **CASSIA**.

The leaves of senna are annually imported from Alexandria, and are used in medicine; their smell is not very strong, but the taste is subacid, bitterish, and nauseous; they are one of the most common purgers of the shops, but are apt to gripe, unless given with proper correctives.

Authors greatly differ with regard to the humours senna brings away, which is a strong proof of its operating universally: it has been greatly praised by some, for bringing away all noxious humours; and it is said to be good in all chronic obstructions, particularly in slow fevers, melancholy, the epilepsy, itch, and other disorders of the skin.

Senna is not good in those disorders in which the fluids are hot, and the solids tend to an inflammation, especially in hæmorrhages and disorders of the breast.

Some authors are in doubt, whether the leaves of senna or the pods are best; there is, however, no great difference, only the pods are said to gripe least, and to be somewhat weaker as a purge. There are scarce any forms of cathartics in which senna is not an ingredient, and it is generally the principal in purgative diet-drinks, and medicated ales.

**SENSATION**, in philosophy, the art of perceiving external objects by means of the senses. See **PERCEPTION**, and the next article.

**SENSE**, a faculty of the soul, whereby it perceives external objects, by means of the impressions they make on certain organs of the body.

The organs of sensation are generally reckoned five, viz. the eye, whereby we see objects; the ear, which enables us to hear sounds; the nose, by which we receive the ideas of different smells; the palate, by which we judge of tastes; and the cutis, or skin, which enables us to feel the different forms, hardness, or softness, of bodies. See **EYE**, **EAR**, &c. as also **VISION**, **HEARING**, &c.

**SENSATIVE SOUL**, a denomination given to the souls of brutes, either as intimating its utmost faculty to be that of sensation; or because it is supposed to be corporeal, so as to be an object of our senses. See **SOUL**.

**SENSITIVE, or SENSIBLE PLANT**, *Mimosa*, in botany. See **MIMOSA**.

**SENSORY**, *Sensorium Commune*, the seat of the common sense, or what receives the impressions of all sensible objects, conveyed to it by the nerves of each particular organ, and consequently is the immediate cause of perception.

This office is, by Dr. Willis, attributed to the striated part of the brain; and by Des Cartes, to the glandula pinealis.

**SENTENCE**, in law, a judgment passed in court by the judge, on some process, either civil or criminal.

**SENTENCE**, in grammar, a period or set of words, comprehending some perfect sense or sentiment of the mind.

**SENTENCE**, in poetry, is an instructive and lively remark made on something very observable and agreeably surprising, which contains much sense in a few words.

It is either direct or plain, as, "In all the affairs of the world, so much reputation is really so much power;" or indirect or disguised, as,

"Fool, not to think how vain  
Against th' Omnipotent to rise in arms."

**SENTIMENTS**, in poetry, and especially dramatic, are the thoughts which the several persons express, whether they relate to matters of opinion, passion, business, or the like.

**SENTINEL, CENTINEL, or CENTRY**, in military affairs, is a private soldier, placed in some post, to watch any approach of the enemy, to prevent surprises, and to stop such as would pass without order, or discovering who they are.

**SEPARATISTS**, an appellation given to dissenters, from their setting up a separate church from the established one.

**SEPTAS**, in botany, a genus of plants, whose flower consists of seven oblong equal petals, double the length of the cup, with seven stamina: the fruit consists of seven oblong, acute, parallel, univalvular capsules, containing many seeds.

**SEPTEMBER**, the ninth month of the year, consisting of only thirty days: it took its name as being the seventh month, reckoning from March, with which the Romans began their year.

**SEPTENTRIO**, in astronomy, a constellation more usually called *ursa minor*. See **URSA**.

In cosmography, the term *septentrio* denotes the same with north: and hence, *septentrional* is applied to any thing belonging to the north, as *septentrional signs*, *parallels*, &c.

**SEPTUAGESIMA**, in the calendar, denotes the third Sunday before Lent, or before quadragesima Sunday: supposed by some to take its name from its being about seventy days before Easter.

**SEPTUAGINT**, the name given to a Greek version of the books of the Old Testament, from its being supposed to be performed by seventy-two Jews, who are usually called the *seventy interpreters*, because seventy is a round number.

The history of this version is expressly written by Aristæas, an officer of the guards to Ptolemy Philadelphus; the substance of whose account is as follows: Ptolemy having erected a fine library at Alexandria, which he took care to fill with the most curious and valuable books from all parts of the world, was informed that the Jews had one, containing the laws of Moses, and the history of that people, and being desirous of enriching his library with a Greek translation of it, applied to the high-priest of the Jews; and to engage him to comply with his request, set at liberty all the Jews, whom his father Ptolemy Soter had reduced to slavery. After such a step, he easily obtained what he desired; Eleazar, the Jewish high-priest, sent back his ambassadors with an exact copy of the Mosaic law, written in letters of gold, and six elders of each tribe, in all seventy-two, who were received with marks of respect by the king, and then conducted into the isle of Pharos, where they were lodged in a house prepared for their reception, and supplied with every thing necessary in abundance. They set about the translation without loss of time, and finished it in seventy-two days; and the whole being read in the presence of the king, he admired the profound wisdom of the law of Moses; and sent back the deputies, laden with presents for themselves, the high-priest, and the temple.

This version was in use to the time of our blessed Saviour, and is that out of which all the citations in the New Testament, from the Old, are taken. It was also the ordinary and canonical translation made use of by the Christian church in the earliest ages; and it still subsists in the churches both of the east and west. It is, however, observable, that the chronology of the Septuagint is different from the Hebrew text. See the article **EPOCHÆ**.

**SEPTUM**, in anatomy, an inclosure, or partition; a term applied to several parts of the body, which serve to separate one part from another.

**SEPULCHRAL**, something belonging to sepulchres, or tombs.

**SEPULCHRE**, a tomb, or place destined for the interment of the dead. This term is chiefly used in speaking of the burying places of the ancients, those of the moderns being usually called tombs.

**SEQUEL**, in logic, the same with conclusion. See the article **CONCLUSION**.

**SEQUESTRATION**, in common law, is setting aside the thing in controversy from the possession of both the parties that contend for it. In which sense it is either voluntary, as when done by the consent of the parties; or necessary, as where it is done by the judge, of his own authority, whether the parties will or not.

**SEQUIN**, a gold-coin, struck at Venice, and in several parts of the grand seignor's dominions. See the article **COIN**.

**SERAGLIO**, a Persian word, which signifies the palace of a prince or lord; in which sense the houses of the ambassadors of England, France, &c. are, at Constantinople, called their *seraglios*. But the term *seraglio* is used, by way of eminence, for the palace of the grand seignor at Constantinople, where he keeps his court, in which his concubines are lodged, and where the youth are trained up for the principal posts of the empire.

**SERAPH**, or **SERAPHIM**, a spirit of the highest rank in the hierarchy of angels; who are thus called, from their being supposed to be most inflamed with divine love, by their nearer and more immediate attendance at the throne of God, and to communicate their fervor to the remoter and inferior orders. See **ANGEL**.

**SERAPHIC**, burning or inflamed with love or zeal, like a seraphim: thus St. Bonaventure is called the *seraphic doctor*, from his abundant zeal and fervor.

**SERAPIAS**, bastard-hellebore, in botany, a genus of plants, whose corolla consists of five ovato-oblong petals, which are spreading, but close at the top; the nectarium is the length of the petals, halloed at the base, cut into three points, the middle being cordated and obtuse; and the others acute; the filaments are two, and short, placed on the pistillum, and topped with erect antheræ: the fruit is an oval, obtuse, three-cornered capsule, having one cell, and containing a great number of scabiform seeds. This genus comprehends the helleborine of Tournefort.

**SERENA**, the same with *coquimbo*. See the article **COQUIMBO**.

*Gutta SERENA*, in medicine. See the article **GUTTA SERENA**.

**SERENADE**, a kind of concert given in the night, by a lover to his mistress, under her window.

**SERENE**, a title of honour given to several princes,

G g

princes, and to the principal magistrates of a republic.

SERGE, in commerce, a woollen stuff manufactured in a loom, of which there are various kinds, denominated either from their different qualities, or from the places where they are wrought; the most considerable of which is the London-erge, which is highly valued abroad, and of which a manufacture has been for some years carried on in France.

SERGEANT, or SERJEANT *at Law*, or of the *Coif*, is the highest degree taken at the common law, as that of doctor is of the civil law; and as these are supposed to be most learned and experienced in the practice of the courts, there is one court appointed for them to plead in by themselves, which is the Common-Pleas, where the common law of England is most strictly observed: but they are not restrained from pleading in any other court, where the judges, who cannot have that honour till they have taken the degree of serjeant at law, call them brothers.

These serjeants are created by the king's writ, commanding them to take upon them that degree therein assigned, under a great penalty: and one or more of these is styled the king's serjeant, who is chosen out of the rest to plead for him in all causes, more especially those of treason, &c.

SERJEANT *at Arms*, or *Mace*, an officer appointed to attend the person of the king, to arrest traitors, and such persons of quality as offend; and to attend the lord high steward when sitting in judgment on a traitor.

The number of these officers is by statute limited to that of thirty: there are now eight at court, who are created with great ceremony; for the person kneeling before the king, his majesty lays the mace on his right shoulder, and says, "Rise up, serjeant of arms, and esquire, for ever." They attend in the presence-chamber, where the band of gentlemen-pensioners wait; and receiving the king at the door, they carry the maces before him, when he goes to chapel, or the house of lords.

There are four other serjeants at arms created in the same manner; one of whom attends the lord chancellor; a second, the lord treasurer; a third, the speaker of the house of commons; and a fourth, the lord-mayor of London, on solemn occasions. There is also an inferior kind of serjeants at mace, who attend the mayor, or the head officer of corporations.

SERGEANT, or SERJEANT, in war, is an inferior officer in a company of foot, or troop of dragoons, armed with an halbard, and appointed to see discipline observed, to teach the soldiers the exercise of their arms, and to order, straiten, and form ranks, files, &c.

SERGEANTY, or SERJEANTY, in law, is

taken for a service that cannot be due from a tenant to any other lord besides the king.

SERIES, in general, denotes a continued succession of things in the same order, and having the same relation or connection with each other: in this sense we say, a series of emperors, kings, bishops, &c.

In natural history, a series is used for an order or subdivision of some class of natural bodies; comprehending all such as are distinguished from the other bodies of that class, by certain characters, which they possess in common, and which the rest of the bodies of that class have not.

SERIES, in mathematics, is a number of terms, whether of numbers or quantities, increasing or decreasing in a given proportion; the doctrine of which has already been given under the article PROGRESSION.

*Infinite* SERIES, is a series consisting of an infinite number of terms, that is, to the end of which it is impossible ever to come; so that the series being carried on to any assignable length, or number of terms, it can be carried yet farther, without end or limitation.

A number actually infinite (that is, all whose units can be actually assigned, and yet is without limits) is a plain contradiction to our ideas about numbers; for whatever number we can conceive, or have any proper idea of, is always determinate and finite; so that a greater after it may be assigned, and a greater after this; and so on, without a possibility of ever coming to an end of the addition or increase of numbers assignable; which inexhaustibility, or endless progression in the nature of numbers, is all we can distinctly understand by the infinity of number; and therefore to say that the number of any thing is infinite, is not saying, that we comprehend their number, but indeed the contrary; the only thing positive in this proposition being this, that the number of these things is greater than any other number which we can actually conceive and assign. But then, whether in things that do really exist, it can be truly said, that their number is greater than any assignable number; or, which is the same thing, that in the numeration of their units one after another, it is impossible ever to come to an end; this is a question about which there are different opinions, with which we have no business in this place; for all that we are concerned here to know, is this certain truth, that after one determinate number, we can conceive a greater, and after this a greater, and so on without end. And therefore, whether the number of any things that do or can really exist all at once, can be such that it exceeds any determinate number, or not, this is true, that of things which exist, or are produced successively one after another, the number may be greater than any assignable one; because though the number of things thus produced, that does actually

actually exist at any time, is finite, yet it may be increased without end. And this is the distinct and true notion of the infinity of a series; that is, of the infinity of the number of its terms, as it is expressed in the definition.

Hence it is plain, that we cannot apply to an infinite series the common notion of a sum, viz. a collection of several particular numbers that are joined and added together one after another, for this supposes that these particulars are all known and determined; whereas the terms of an infinite series cannot be all separately assigned, there being no end in the numeration of its parts, and therefore it can have no sum in sense. But again, if we consider that the idea of an infinite series consists of two parts, viz. the idea of something positive and determined, in so far as we conceive the series to be actually carried on; and the idea of an inexhaustible remainder still behind, or an endless addition of terms that can be made to it one after another; which is as different from the idea of a finite series as two things can be: hence we may conceive it as a whole of its own kind, which therefore may be said to have a total value whether that be determinable or not. Now in some infinite series this value is finite or limited; that is, a number is assignable beyond which the sum of no assignable number of terms of the series can ever reach, nor indeed ever be equal to it, yet it may approach to it in such a manner, as to want less than any assignable difference; and this we may call the value or sum of the series; not as being a number found by the common method of addition, but as being such a limitation of the value of the series, taken in all its infinite capacity, that if it were possible to add them all one after another, the sum would be equal to this number.

Again, in other series the value has no limitation; and we may express this, by saying, the sum of the series is infinitely great; which indeed signifies no more than that it has no determinate and assignable value; and, that the series may be carried such a length as its sum, so far, shall be greater than any given number. In short, in the first case we affirm there is a sum, yet not a sum taken in the common sense; in the other case we plainly deny a determinate sum in any sense.

**Theorem I.** In an infinite series of numbers, increasing by an equal difference or ratio (that is, an arithmetical or geometrical encreasing progression) from a given number, a term may be found greater than any assignable number.

Hence, if the series encrease by differences that continually encrease, or by ratios that continually encrease, comparing each term to the preceding, it is manifest that the same thing must be true, as if the differences or ratios continued equal.

**Theorem II.** In a series decreasing in infinitum in a given ratio, we can find a term less than any assignable fraction.

Hence, if the terms decrease, so as the ratios of each term to the preceding do also continually decrease, then the same thing is also true, as when they continue equal.

**Theor. III.** The sum of an infinite series of numbers all equal, or encreasing continually, by whatever differences or ratios, is infinitely great; that is, such a series has no determinate sum, but grows so as to exceed any assignable number.

**Demonf. 1.** If the terms are all equal, as  $A : A : A$ , &c. then the sum of any finite number of them is the product of  $A$  by that number, as  $A n$ ; but the greater  $n$  is, the greater is  $A n$ ; and we can take  $n$  greater than any assignable number; therefore  $A n$  will be still greater than any assignable number.

Secondly, suppose the series encreases continually (whether it do so infinitely or limitedly) then its sum must be infinitely great, because it would be so if the terms continued all equal, and therefore will be more so, since they encrease. But if we suppose the series encreases infinitely, either by equal ratios or differences, or by encreasing differences or ratios of each term to the preceding; then the reason of the sums being infinite will appear from the first theorem; for in such a series, a term can be found greater than any assignable number, and much more therefore the sum of that and all the preceding.

**Theor. IV.** The sum of an infinite series of numbers decreasing in the same ratio, is a finite number, equal to the quote arising from the division of the product of the ratio and first term, by the ratio less by unity; that is, the sum of no assignable number of terms of the series can ever be equal to that quote; and yet no number less than it, is equal to the value of the series, or to what we can actually determine in it; so that we can carry the series so far, that the sum shall want of this quote less than any assignable difference.

**Demonf. 2.** To whatever assigned number of terms the series is carried, it is so far finite; and if the greatest term is  $l$ , the least  $A$ , and the ratio  $r$ , then the sum is  $S = \frac{rl - A}{r - 1}$ . See *Geometrical PROGRESSION*.

Now, in a decreasing series from  $l$ , the more terms we actually raise, the last of them,  $A$  becomes the lesser, and the lesser  $A$  be,  $rl - A$  is the greater, and so also is  $\frac{rl - A}{r - 1}$ ; but  $rl - A$  being still less than  $rl$ , therefore  $\frac{rl - A}{r - 1}$  is still less than  $\frac{rl}{r - 1}$ , that is, the sum of any assignable number of the terms of the series is still less than the quote mentioned, which is  $\frac{rl}{r - 1}$ , and this is the first part of the theorem.

Again, the series may be actually continued so far,

far, that  $\frac{rl-A}{r-1}$  shall want of  $\frac{rl}{r-1}$  less than any assignable difference; for, as the series goes on, A becomes less and less in a certain ratio, and so the series may be actually continued till A becomes less than any assignable number (by Theorem II) now  $\frac{rl}{r-1} - \frac{rl-A}{r-1} = \frac{A}{r-1}$ , and  $\frac{A}{r-1}$  is less than A; therefore, let any number assigned be called N, we can carry the series so far till the last term A be less than N; and because  $\frac{rl-A}{r-1}$  wants of  $\frac{rl}{r-1}$ , the difference  $\frac{A}{r-1}$ , which is less than A, which is also less than N, therefore the second part of the theorem is also true, and  $\frac{rl}{r-1}$  is the true value of the series.

Scholium. The sense in which  $\frac{rl}{r-1}$  is called the sum of the series, has been sufficiently explained; to which, however, we shall add this: that whatever consequences follow from the supposition of  $\frac{rl}{r-1}$

being the true and adequate value of the series taken in all its infinite capacity, as if the whole were actually determined and added together, can never be the occasion of any assignable error in any operation or demonstration where it is used in that sense; because, if it is said that it exceeds that adequate value, yet it is demonstrated that this excess must be less than any assignable difference, which is in effect no difference, and so the consequent error will be in effect no error: for if any error can happen from  $\frac{rl}{r-1}$

being greater than it ought to be, to represent the complete value of the infinite series, that error depends upon the excess of  $\frac{rl}{r-1}$  over that complete

value; but this excess being unassignable, that consequent error must be so too; because still the less the excess is, the less will the error be that depends upon it. And for this reason, we may justly enough

look upon  $\frac{rl}{r-1}$  as expressing the adequate value of the infinite series. But we are farther satisfied of the reasonableness of this, by finding in fact, that a finite quantity does actually convert into an infinite series, which happens in the case of infinite decimals. For example,  $\frac{2}{3} = .6666$ , &c. which is plainly

a geometrical series from  $\frac{6}{10}$  in the continual ratio of 10 to 1; for it is  $\frac{6}{10} + \frac{6}{100} + \frac{6}{1000} + \frac{6}{10000}$ , &c.

And reverely, if we take this series, and find its sum by the preceding theorem, it comes to the same

$\frac{2}{3}$ ; for  $l = \frac{6}{10}$ ,  $r = 10$ , therefore  $rl = \frac{60}{10} = 6$ ;

and  $r-1 = 9$ ; whence  $\frac{rl}{r-1} = \frac{6}{9} = \frac{2}{3}$ .

Theorem V. In the arithmetic progression 1, 2, 3, 4, &c. the sum is to the product of the last term, by the number of terms, that is, to the square of the last term; in a ratio always greater than 1:2, but approaching infinitely near it. But if the arithmetical series begins with 0, thus, 0, 1, 2, 3, 4, &c. then the sum is to the product of the last term, by the number of terms, exactly in every step as 1 to 2.

Theorem VI. Take the natural progression, beginning with 0, thus, 0, 1, 2, 3, &c. and take the squares of any the like powers of the former series; as the squares, 0, 1, 4, 9, &c. or cubes, 0, 1, 8, 27; and then again take the sum of the series of powers to any number of terms, and also multiply the last of the terms summed by the number of terms (reckoning always 0 for the first term) the ratio of that sum, to that product is more than

$\frac{1}{n \times 1}$  ( $n$  being the index of the powers) that is, in the series of squares it is more than  $\frac{1}{3}$ ; in the cubes more than  $\frac{1}{4}$ ; and so on: but the series going on in infinitum, we may take in more and more terms without end into the sum; and the more we take, the ratio of the sum to the product mentioned, grows less and less; yet so as it never can actually be equal to  $\frac{1}{n \times 1}$  but approaches infinitely near to it, or within less than an assignable difference.

SERIOLOA, in botany, a genus of plants, whose flower is compound, imbricated, and uniform; the florets which compose it are each monopetalous, ligulated, linear, truncated, and quinque-dentated; there is no pericarpium, but the seeds, which are oblong and crowned with down, are contained in the cup, and placed on a paleaceous receptacle.

This genus comprehends the achyrophorus of Vaillant.

SEROSITY, in medicine, denotes an overabundance of serum. See the articles SERUM and BLOOD.

SERPENS, in astronomy, a constellation in the northern hemisphere, called more particularly *Serpens Ophiuchi*.

The stars in the constellation Serpens, in Ptolemy's catalogue, are 17; in Tycho's, 19; in the Britannic catalogue, 59. The longitudes, latitudes, magnitudes, &c. are as follow:

SERIPHIMUM, in botany, a genus of plants, whose flower-cup is double; the corolla is monopetalous and funnel-shaped, with the limb quinque-dentated; the stamina are five capillary filaments, topped with cylindraceous antheræ; there is no pericarpium, but the cup, which is immutable, contains an oblong solitary seed.

This genus comprehends the *helichryfoides* of Vaillant.

SERPENT, *Serpens*, in zoology, a general term for all amphibious animals without legs. See the article AMPHIBIOUS.

Mr. Ray defines serpents to be creatures breathing by means of lungs, having only one ventricle in the heart, having no feet, and having a long body covered with scales. To which he adds, that in cold seasons they can bear hunger a long time. The greater part of the serpent class are poisonous, and dangerous in their bite, leaving a mischievous liquor in the wound made by their tooth, which mixing by this means immediately with the blood, is of fatal consequence; though the whole creature may

be eaten with safety, or even the poisonous liquor, which does this mischief in the wound, tasted without hurt.

SERPENTARIA, snake-root, in botany and pharmacy, the name of a species of aristolochia, or birthwort, with auriculated leaves. See the article ARISTOLOCHIA.

It obtained the name of snake-root as being accounted a specific against venomous bites; but whatever truth there may be in that, it is undoubtedly an excellent diuretic, diaphoretic, and alexipharmic medicine, and is frequently given in malignant fevers and epidemical diseases. It may be given in substance from ten to thirty grains, in powder and in infusion, to two drams.

SERPENTARIUS, in astronomy, a constellation of the northern hemisphere, called also Ophiuchus, and anciently Æsculapius.

The stars in the constellation Serpentarius, in Ptolemy's catalogue, are 29; in Tycho's, 25; and in the Britannic, 69. The longitudes, latitudes, magnitudes, &c. are as follow:

SERPENTINE, in general, denotes any thing that resembles a serpent: hence, the worm or pipe of a still, twisted in a spiral manner, is termed a serpentine worm.

SERPENTINE MARBLE, *Ophites*, a species of marble, so called from its being variegated with streaks and spots like the skin of a serpent. See the article MARBLE.

SERPENTINE VERSES, such as begin and end with the same words.

SERPIGO, in medicine, a species of herpes. See HERPES.

SERPILLUM, mother of thyme, in botany, a species of thyme. See THYME.

SERRATED, in general, something indented or notched, in the manner of a saw; a term much used by botanists in the description of the leaves of plants: they are said to be simply serrated, when the margin is equally cut into sharp imbricated angles, that point towards the extremity of the leaf, as those of the rose-tree; and duplicately serrated, when the edges of the large serratures are again serrated with lesser indentings of the same kind; such are the leaves of the common elm-tree.

SERRATULA, saw-wort, in botany, a genus of plants, whose flower is compound, tubulous, and uniform; the partial ones are monopetalous, hermaphrodite, funnel-shaped, and quinquefid at the limb: there is no pericarpium, but the seeds, which are solitary, oval, and crowned with a long sessile down, are contained in the cup, having a pilose plane receptacle.

The common saw-wort, which grows in many parts of England, is accounted a vulnerary plant, and is said to be good to dissolve coagulated blood; but at present it is not much in use.

SERRATUS, in anatomy, a name given to several muscles from their resemblance to a saw.

SERVANT, a term of relation, signifying a person who owes and pays a limited obedience for a certain time, to another in quality of master.

If any servant, who is hired for a year, depart before the end of his term, without reasonable cause, to be allowed by a justice of the peace; or, after the term is expired, without giving a quarter's warn-

ing, he is liable to be committed to prison by two justices, till he gives security to serve out the time: or he may, by one justice, be sent to the house of correction, there to be punished as a disorderly person, 7 Jac. I. c. 4.

On the other hand, a master cannot put away his servant before the end of the term he was hired for, without some reasonable cause allowed by a justice of the peace; nor after the expiration of the term, without a quarter's warning given, on pain of forfeiting 40s.

Where a servant that is hired for a year happens to fall sick, such servant ought not to be discharged, nor his wages abated on that account.

SERVETISTS, a name given to the modern Antitrinitarians, from their being supposed to be the followers of Michael Servetus, who, in the year 1559, was burnt at Genoa, together with his books.

SERVICE, in law, is a duty which a tenant, on account of his fee, owes to his lord.

SERVICE-TREE, *Sorbus*, in botany. See the article SORBUS.

SERVITES, a religious order in the church of Rome, founded about the year 1233, by seven Florentine merchants, who, with the approbation of the bishop of Florence, renounced the world, and lived together in a religious community on mount Senar, two leagues from that city.

SERVITOR, in the university of Oxford, a student who attends on another for his maintenance and learning.

SERUM, a thin, transparent, saltish liquor, which makes a considerable part in the mass of blood. See the article BLOOD.

SESAMOIDA OSSA, in anatomy, several small bones that somewhat resemble the seed of the sesamum, whence their name.

SESAMUM, oily-grain-plant, in botany, a genus, whose flower is monopetalous, campanulated, and ringent; the faux is inflated, patent, and very large, and the limb is cut into five parts, four of which are almost equal, and the fifth is twice their length, ovate and upright: the stamina are four, two of which are shorter than the others; and the

the fruit is an oblong, compressed, acuminate capsule, slightly four-cornered, having four cells, which contain many almost oval seeds.

The flowers of this genus resemble those of the fox-glove, but the fruit is different. The seeds of a species of this plant, which grows naturally in India, and cultivated in Carolina, yield, upon expression, a larger quantity of oil than almost any other known vegetable. The seeds of this plant are also used by the negroes for food, which they parch over the fire, and mix them with water, and by stewing other ingredients with them, make a hearty food. Sometimes a kind of pudding, called benny, or bonny, is made of these seeds, in the same manner as with rice, and is by some much esteemed, but is never used for these purposes in England.

**SESELI**, Dutch sarisage, in botany, a genus of umbelliferous plants, whose general corolla is uniform; the single flowers consist each of five inflexed heart-shaped petals, which are slightly unequal, and contain five subulated stamina: the fruit is small, ovate, channeled, and separable into two parts, each part containing an oval seed, plane on one side and striated on the other.

**SESQUI**, a Latin particle, signifying a whole and a half, which joined with *altera*, *terza*, *quarta*, &c. is much used in the Italian music, to express a kind of ratios, particularly several species of triples. See the article **TRIPLE**.

**SESQUI-ALTERAL Proportion**, in geometry and arithmetic, is when any number or quantity contains another once and a half; and the number so contained in the greater, is said to be to it in sub-*sesqui*-alteral proportion. See the article **PROPORTION**.

**SESQUI-DUPLICATE Proportion**, is when of two terms the greater contains the less twice, with half another over.

**SESQUI-QUADRATE**, an aspect or position of the planets, when they are at the distance of four signs and a half, or 135 degrees from each other; and *sesqui*-quintile is an aspect of the planets when they are 180 degrees from each other.

**SESQUI-TERTIONAL Proportion**, is when any number or quantity contains another once and one-third.

**SESSILE ROOTS**, among botanists, such tuberous roots as adhere to the base of the stalk. And a sessile leaf expresses a leaf immediately fixed to the stalk or root, without any petiole.

**SESSION**, *Sessio*, in general, denotes each sitting or assembly of a council, &c.

**SESSION of Parliament**, is the season or space from its meeting to its prorogation. See the article **PARLIAMENT**.

**SESSION**, in law, denotes a sitting of justices in court upon their commission; as the sessions of oyer and terminer, the quarter-sessions, otherwise called the general or open sessions of the peace, in opposi-

tion to what is called a *privy-session*, held upon special occasions for speedier dispatch of justice.

**SESTERCE**, *Sestertius*, a silver coin in use among the Romans.

Some authors make two kinds of *sesterces*, the less, called *sestertius*, in the masculine gender, and the great one, called *sestertium*, in the neuter, the latter containing a thousand of the other.

Others will have any such distinction of great and little *sesterces* unknown to the Romans; *sestertius*, say they, was an adjective, and signified *as sestertius*, or two ases and a half, and when used plurally, as in *quinquaginta sestertium*, or *sestertia*, it was only by way of abbreviation, and there was always understood *millia*, or thousands.

*Sesterce*, or *sestertius*, was also used by the ancients, for a thing containing two wholes and a half of another, as *as* was taken for any whole or integer. See the article **INTEGER**.

**SESUVIUM**, in botany, a genus of plants, whose flower hath no corolla; the cup is formed of one campanulated leaf, divided into five ovate acute segments, which are coloured; below the lacinæ of the cup are inserted a number of subulated filaments, topped with roundish antheræ: the fruit is an ovate capsule, with three cells, containing roundish seeds.

**SET**, or **SETs**, a term used by farmers and gardeners, to express the young plants of the white-thorn and other shrubs, with which they use to raise their quick or quick-set hedges.

**SETHIANS**, in church history, Christian heretics, so called, because they paid divine worship to Seth, whom they looked upon to be Jesus Christ the Son of God, but who was made by a third Divinity, and substituted in the room of the two families of Abel and Cain, which had been destroyed by the deluge.

These heretics appeared in Egypt in the second century, and as they were addicted to all sorts of debauchery, they did not want for followers, and continued in Egypt above two hundred years.

**SETON**, in surgery, a few horse-hairs, small threads, or large packthread, drawn through the skin, chiefly the neck, by means of a large needle or probe, with a view to restore or preserve health.

We find by experience, that setons are very useful in the hydrocephalus, catarrhs, inflammations, and other disorders, particularly those of the eyes, as a gutta serena, cataract, and incipient suffusion; to those we may add intense head-achs, with stupidity, drowsiness, epilepsies, and even an apoplexy itself.

**SETTER**, among farmers. To *setter* is to cut the dewlap of an ox or cow, and into the wound to put the root of the helleboraster, whereby an issue is made for ill humours to vent themselves.

**SETTING**, in astronomy, the withdrawing of a star or planet, or its sinking below the horizon.

Astronomers and poets make three different kinds of setting of the stars, viz. the cosmical, acronycal, and helical.

**SETTING**, in the sea language. To set the land or the sun, by the compass, is to observe how the land bears on any point of the compass, or on what point of the compass the sun is. Also, when two ships sail in sight of one another, to mark on what point the chased bears, is termed setting the chase by the compass.

**SETTING**, among sportsmen, a term used to express the manner of taking partridges by means of a dog peculiarly trained to that purpose.

**SEVENTH**, *Septima*, in music, an interval called by the Greeks heptachordon, whereof there are four kinds; first, the defective seventh, consisting of three tones, and three greater semitones; the second, called by Zarlino and the Italians, *demi-ditono con diapente*, or *settimo minore*, is composed diatonically of seven degrees and six intervals, four whereof are tones, and the rest greater semitones, and chromatically of ten semitones, six whereof are greater, and four less; it takes its form from the ratio *quadruparziante quinto*, as 9:5. The third, called by the Italians *il ditono con diapente*, or *settimo maggiore*, is composed diatonically of seven degrees, like the former, and six intervals, five whereof are tones and a major semitone, so that only a major semitone is wanting to make up the octave, and chromatically of twelve semitones, six greater and six less. It takes its form from the ratio of 15:8. The fourth is redundant, and composed of five tones, a greater semitone and a less, so that it wants only a comma of an octave, that is, so much as to make its second semitone greater, called *pentatonon*. Hence many confound it with the octave, maintaining, with good reason, that only the three first sevenths can be of any use.

**SEVERANCE**, in law, the singling or separating of two or more joined in one writ.

**SEVERANCE of Corn**, signifies the cutting and carrying the same off the ground; and sometimes it is taken for the setting out the tithe from the rest of the corn.

**SEWER**, in the household, an officer who comes in before the meat of a king or nobleman, to place and range it on the table.

**SEWER** is also a passage or gutter made to carry water into the sea or a river, whereby to preserve the land, &c. from inundations and other annoyances.

The business of the commissioners of sewers, or their office in particular, is to repair sea-banks and walls, survey rivers, public streams, ditches, &c. and to make orders for that purpose. See the article **COMMISSION**.

**SEX**, *Sexus*, something in the body which distinguishes male from female.

**SEXAGENARY**, something relating to the number sixty: thus sexagenary or sexagesimal arithmetic, is a method of computation proceeding by sixties; such is that used in the division of a degree into sixty minutes, of the minute into sixty seconds, of the second into sixty thirds, &c.

Also sexagenary tables are tables of proportional parts, shewing the product of two sexagenaries that are to be multiplied, or the quotient of the two that are to be divided.

**SEXAGESIMA**, the second Sunday before Lent, or the next to Shrove-Sunday; so called, as being about the sixtieth day before Easter.

**SEXAGESIMALS**, or *Sexagesimal Fractions*, fractions whose denominators proceed in a sexagesuple ratio; that is, a prime, or the first minute =  $\frac{1}{60}$ ; a second =  $\frac{1}{3600}$ ; a third =  $\frac{1}{216000}$ .

Anciently there were no other than sexagesimals used in astronomy, and they are still retained in many cases, though decimal arithmetic begins to grow in use now in astronomical calculations. In these fractions which some call astronomical fractions, the denominator being always sixty, or a multiple thereof, is usually omitted, and the numerator only written down, thus, 4°, 59', 32", 50"', 16''', is to be read four degrees, fifty-nine minutes, thirty-two seconds, fifty thirds, sixteen fourths, &c.

**SEXANGLE**, in geometry, a figure having six sides, and consequently six angles.

**SEXTANT**, in mathematics, denotes the sixth part of a circle, or an arch comprehending sixty degrees.

**SEXTILE**, *Sextilis*, the position or aspect of two planets, when at sixty degrees distance, or at the distance of two signs from one another. It is marked thus (\*). See the article **ASPECT**.

**SEXTON**, a church-officer, whose business is to take care of the vessels, vestments, &c. belonging to the church, and to attend the minister, churchwardens, &c. at church. He is usually chosen by the parson only.

**SEXTUPLE**, *Sestuplo*, in music, denotes a mixed sort of triple which is beaten in double time. See **TRIPLE**.

**SEXUALISTÆ**, among botanical writers, those who have established the classes of plants upon the differences of the sexes and parts of fructification in plants, according to the modern method, as Linnaeus, &c. See **BOTANY**.

**SHACK**, in ancient customs, a liberty of winter pasturage.

In the counties of Norfolk and Suffolk, the lord of the manor has shack; that is, a liberty of feeding his sheep at pleasure in his tenants lands, during the six winter months.

**SHAD**, *Alausa*, in ichthyology, a species of clupea, with the upper jaw bifid at the extremity, and spotted with black: it greatly resembles the common herring,

herring, and is, on that account, sometimes called the mother of herring: all the fins are whitish, except that on the back: the tail is very much forked.

**SHADOW**, *Umbra*, in optics, a privation or diminution of light, by the interposition of an opaque body; or, it is a plane where the light is either altogether obstructed, or greatly weakened, by the interposition of some opaque body between it and the luminary.

A shadow of itself is invisible; and, therefore, when we say we see a shadow, we partly mean that we see bodies placed in the shadow, and illuminated by light reflected from collateral bodies; and, partly, that we see the confines of the light. See the article **LIGHT**.

If the opaque body that projects the shadow be perpendicular to the horizon, and the place it is projected on be horizontal, the shadow is called a right shadow; and such are the shadows of men, trees, buildings, mountains, &c. But if the opaque body be placed parallel to the horizon, the shadow is called a versed shadow; as the arms of a man stretched out, &c.

*The Laws of the Projection of SHADOWS from opaque Bodies.* — 1. Every opaque body projects a shadow in the same direction with its rays; that is, towards the part opposite to the light. Hence, as either the luminary or the body changes place, the shadow likewise changes. 2. Every opaque body projects as many shadows as there are luminaries to enlighten it. 3. As the light of the luminary is more intense, the shadow is the deeper: hence, the intensity of the shadow is measured by the degrees of light that space is deprived of. 4. If a luminous sphere be equal to an opaque one it illuminates, the shadow, which this latter projects, will be a cylinder, and consequently will be propagated still equal to itself, to whatever distance the luminary is capable of acting; so that if it be cut in any place, the plane of the section will be a circle, equal to a great circle of the opaque sphere. 5. If the luminous sphere be greater than the opaque one, the shadow will be conical. If, therefore, the shadow be cut by a plane, parallel to the base, the plane of the section will be a circle; and that so much the less as it is a greater distance from the base. 6. If the luminous sphere be less than an opaque one, the shadow will be a truncated cone; and, consequently, grows still wider and wider; and, therefore, if cut by a plane, parallel to the section, that plane will be a circle, so much the greater as it is farther from the base.

*Of SHADOWS from the Sun.* — The sun being vastly larger than the whole globe of the earth, must give all its shadows pointed, by reason it illuminates more than half of them.

In consequence of this demonstration, we might conclude, that all the sun's shadows must be less than the bodies that project them, and diminished

more and more as they recede further and further. Now this would be true were there any relation between the body illuminated and the body illuminating; but as all objects on the earth are so small in comparison of that star, the diminution of their shadows is imperceptible to the eye, which sees them always equal, i. e. either broader or narrower than the body that forms them; on this account all the shadows caused by the sun are made in parallels.

From the whole it appears, that to find the shadow of any body whatever opposed to the sun, a line must be drawn from the top of the luminary perpendicular to the place where the foot of the luminary is to be taken: and through this place an occult line is to be drawn through one of the angles of the plan of the object, and another from the sun to the same object; and the intersection of the two lines will shew how far the shadow is to go; all the other lines must be drawn parallel hereto.

The shadows of the sun are equal in objects of the same height, though at a distance from each other. See plate **LXXXI.** fig. 8.

Experience teaches, that stiles, or elevations of the same height, removed to a distance from each other, do yet project equal shadows at the same time: for they are lengthening and shortening, in proportion as the sun comes nearer, or recedes further off; one or other of which he is continually doing.

For this reason, when the shadow of an object is to be cast any way, you must determine the place of the sun, and the point underneath, to draw two occult lines from the same, for the extremity of the shadow; as here the palisade A gives the extreme of its shadow in B: and if from this point B, you draw a point of sight C, this line BC will be the shadow of the palisade D, as well as that of A, and of all the rest in the same line to the very point of sight.

In effect, it must be held for a certain maxim, that shadows always retain the same point of sight as the objects. On the footing of this observation, that objects of the same height give equal shadows: if you would give the shadow of the palisades, E, F, which are of the same height as A, D, take in your compasses the distance AD, and set it on the foot of the palisade E, by which you will have EG; then from G draw a line to the point of sight C; and thus you are to proceed, let the number of walks be ever so great.

Though the sun is made to appear in this figure, it must not be supposed that he is so near the objects; the design being only to shew, that the rays proceed from him in this manner, when at such a height, though far without the limits of the piece; as fig. 9, which yet has the line for the foot of the object AB; and those of the rays of the sun C, C, because these are always required for finding the extremities of the shadows.

The

The shadow of the object O is found by continuing the line A B, and making it rise over the steps, and against the wall, till cut by the ray in the point S, by the rays passing over the corner of the object, and from S drawing a line to the point of sight T.

To find the shadow of the object P, it must be remembered, that the foot of the light must always be supposed on the plane where the object is placed. Accordingly, the ray C, cutting the little line A B, shews how far the shadow of the little object P must go, to be thence drawn to the point of sight T. The object V casts its shadow all along, though in its way it descends into a ditch.

The shadow of the wall R is found by the same rule as the rest; as appears by the lines A B and the ray C.

*SHADOWS by Torch-light.* The shadow of an erect pyramid by torch-light falls as it would by the light of the sun; and in both cases there is but one line, whereon the vertical point of the pyramid will be found.

*SHADOWS on several parallel Planes.* The first plane here is the floor, whereon the chair A (plate LXXXI. fig. 10.) stands; the second plane is the upper part of the table, parallel to the first, and may be either above or below it. There might also be more of these planes, wherein to find the foot of the illuminating body, in order to come at the shadow of the object. Suppose the foot of the illuminating body to be C, and the upper flame B; from the points C and B draw lines through the upper and under parts of the object D, which will give the shadow E upon the table.

To find the shadow of the chair A, which is placed on the ground, determine the foot of the luminary on the table in C on the ground: this is easy by the following instructions. From the point of distance, which is here supposed to be without the limits of the paper, draw a line through the foot of the table F; then from the angle G upon the table let fall a perpendicular, cutting the line F in the point H, and from H draw a parallel to the base H I, which is equal to the upper part of the table, and will direct to the thing required. For drawing a line from the point of sight K, through the foot of the luminary C, to the extremity of the table L; from the same point L, let fall a perpendicular to H I, which will give the point M.

Then from M draw a line to the point of sight K, in which line M K the foot of the luminary will be found.

To determine the precise point, let fall a perpendicular from the point C, which, cutting the line M H, will give the point N for the foot of the luminary.

This point N being thus found, there will be no difficulty in finding the shadow of the chair A, the method being the same as for the other objects

taught before, that is, from the foot of the luminary N draw the lines through all the angles of the plane of the chair, and other lines through the upper part of the chair from the luminary B; these latter, by intersecting the former, express the bounds of the shadow. For the rest, the figure gives sufficient directions.

When two luminaries shine on the same object, two shadows must be produced; each of the luminaries occasioning its respective shadow, and that in proportion to the circumstances of the luminary.

If such luminaries, when at equal distances, be equal, the shadows themselves must be equal: but if there be any disproportion, that is, if one of them be a little bigger than the other, or one of them a little nearer the object than the other, the shadows will be unequal.

From what has been observed before, may be drawn this conclusion, that the same object may project shadows of divers forms, though still illumined on the same side; the sun giving one form, the torch another, and the day-light no precise form at all.

The sun always makes its shadow equal to the object, that is, projects it parallel-wise.

It is certainly of consequence to all painters, engravers, &c. to observe these rules precisely, and not to take the rules for candles, lamps, and the like, in lieu thereof, as is too frequently done.

The shadow of a torch, or flambeau, is not projected in parallel lines, but in rays proceeding from a center; whence the shadow is never equal to the body, but always bigger, and grows more so as it recedes farther off. It appears therefore a gross abuse to represent the shadow of a torch like that of the sun, and the shadow of the sun like that of a candle, when the difference is so considerable.

There is a third kind of shadow, neither produced by the sun nor a torch; but only a fine sunny day, which wanting strength to finish and define its form, occasions a dimness near the object. Now for this there is no certain rule, but every body conducts it at discretion.

All these shadows, both of the sun, of the torch, and of the day-light, must appear darker than the parts of objects not illuminated; and that part of the shadow that is most remote from the object must be still darker than that nearer it.

*SHADOW, in geography.* The inhabitants of the terraqueous globe of the earth receive different denominations according to the different ways wherein their shadows are projected; as ascii, amphiscii, heteroscii, and periscii. See the articles, ASCII, &c.

*SHADOW, in painting,* an imitation of a real shadow, effected by gradually heightening and darkening the colours of such figures, as by their dispositions cannot receive any direct rays from the luminary that is supposed to enlighten the piece.

The management of the shadows and lights makes what the painters call *claro-obscuro*. See *CLARO OBSCURO*. *Genesis of curves* by SHADOWS. See the article *CURVE*.

SHADDOCK, in botany, a species of citrus. See the article *CITRUS*.

SHAFT, of a Column, in building, is the body thereof between the base and capital: so called from its straightness. See the article *COLUMN*.

SHAFT, in mining, is the pit or hollow entrance into it. See *MINE*.

SHAGREEN, or CHAGREEN, in commerce, a kind of grained leather, prepared, as is supposed, of the skin of a species of squalus, or hound-fish, called the shagreen, or shagrain; and much used in covering cases, books, &c.

It is imported from Constantinople, Tauris, Tripoli, Algiers, and from some parts of Poland, where it is prepared in the following manner; The skin being stretched out, is first covered over with mustard seed, which is bruised upon it: and being thus exposed to the weather for some days, it is then tanned.

The best is of a brownish colour, as the white sort is the worst: it is extremely hard; yet, when steeped in water, it becomes soft and pliable; and being fashioned into case-covers, it readily takes any colour, as red, green, yellow, black, according to the fancy of the workman.

SHAKLES, in a ship, are the rings with which the ports are shut fast, by lashing the port-bar to them. There are also shakles put upon bilbowbolts, for confining the men who have deserved corporal punishment.

SHALLOT, or ESCHALOTTES, in botany, a small species of onion, much used in modern cookery. For its generical characters, see *ONION*.

SHAMADE, or CHAMADE. See the article *CHAMADE*.

SHAMBLES, among miners, a sort of niches, or landing places, left at such distances in the adits of mines, that the shovel-men may conveniently throw up the ore from shamble to shamble, till it comes to the top of the mine. See *DIGGING*, *MINE*, &c.

SHAMMY, or CHAMOIS-LEATHER, a kind of leather, dressed either in oil, or tanned; and much esteemed for its softness, pliancy, and being capable of bearing soap without hurt.

SHANK, in the manege, that part of a horse's fore-leg which lies between the knee and the fetlock.

SHANK-PAINTER, in a ship, a short chain fastened under the fore-shrouds, by a bolt, to the ship's side; having at the other end a rope spliced to the chain, on which the after part of the anchor rests when it lies by the ship's side.

SHANKER, or CHANCER, in medicine, a

malignant ulcer, usually occasioned by some venereal disorder. See the articles *GONORRHOEA* and *Pox*.

Shankers are generally situated on those parts which have a fine and tender covering, as the inward duplicature of the prepuce in men, the inside of the pudenda in women, the nipples of nurses, and the lips and tongue of prostitutes: in very bad cases they will appear on the dorsum penis, as well as on the pubes and inside of the thighs.

SHARE of a Plough, that part which cuts the ground, the extremity forwards being covered with a sharp-pointed iron, called the point of the share; and the end of the wood behind, the tail of the share. See *PLOUGH*.

SHARP, in music, a kind of artificial note; for the character and use of which, see the articles *CHARACTER*, *FLAT*, *SCALE*, &c.

SHARP, in the sea-language, signifies to hale taut, or tight.

SHEARING, or SHEERING. See the article *SHEERING*.

SHEAT of a Plough, a part passing through the beam, and fastened to the share. See the articles *PLOUGH* and *SHARE*.

SHEATING, in the sea-language, is the casing that part of a ship, which is to be under water, with fir-board of an inch thick; first laying hair and tar, mixed together under the boards, nailing them on, in order to prevent worms from eating the ship's bottom.

SHEATS, in a ship, are ropes bent to the clews of the sails; serving, in the lower sails, to haul aft the clews of the sail; but, in top-sails, they serve to haul home the clew of the sail close to the yard-arm.

SHEEP, *Ovis*, in zoology, a well known genus of quadrupeds, the horns of which are hollow, bent backward, twisted, and rugose: the fore-teeth are eight, and the hinder ones are narrower than the others; there are no canine, or dog-teeth.

As to the choice of sheep to breed, the ram should be young, and his skin of the same colour with his wool, for the lambs will be of the same colour with the skin. He should have a large long body, a broad forehead, round, and well rising, large eyes, and strait and short nostrils. The polled sheep, that is those which have no horns, are found to be the best breeders. The ewe should have a broad back, a large bending neck, small, but short, clean and nimble legs, and a thick deep wool covering her all over. To know whether they be sound or not, the farmer should examine the wool, that none of it be wanting, and see that the gums be red, the teeth white and even, the brisket skin red, the wool firm, the breath sweet, and the feet not hot. Two years old is the best time for beginning to breed, and their first lambs should not be kept too long to weaken them by suckling, but be sold as

soon as conveniently may be. They will breed advantageously till they are seven years old.

The farmers have a method of knowing the age of a sheep, as that of a horse is known by the mouth. When a sheep is one shear, as they express it, it has two broad teeth before; when it is two shears, it will have four; when three, six; and when four, eight: after this their mouths begin to break. The difference of land makes a very great difference in the sheep.

The fat pastures breed frait, tall sheep, and the barren hills and downs breed square short ones; woods and mountains breed tall and slender sheep; but the best of all are those bred upon new-plowed land, and dry grounds. On the contrary, all wet and moist lands are bad for sheep, especially such as are subject to be overflowed, and to have sand and dirt left on them. The salt marshes are, however, an exception to this general rule, for their saltness makes amends for their moisture; any thing of salt, by reason of its drying quality, being of great advantage to sheep.

Sheep's dung is one of the best manures we know, succeeding better on cold lands than any other dung whatever; but as it is not so easily collected as the dung of large animals, it is commonly conveyed to the land it is intended for, by folding the sheep upon it. See the articles DUNG and FOLDING.

Sheep-stealing, or killing them, in order to obtain their fat, &c. is felony without benefit of clergy.

SHEERING, or SHEARING, in the woollen manufacture, is the cutting off, with large sheers, the too long nap, in order to make the cloth more smooth and even. See the article CLOTH.

SHEERING, in the sea-language; when a ship is not steered steadily, they say she sheers, or goes sheering; or, when at anchor, she goes and in out, by means of the current of the tide, they also say she sheers.

SHEERS, in a ship, are two masts set across at the upper end of each other; a contrivance generally used for setting or taking out the masts of a ship, where there is no hulk to do that office.

SHEKEL, in Jewish antiquity, an ancient coin, worth 2s. 3 $\frac{1}{4}$ d. sterling.

SHELF, among miners, the same with what they otherwise call fast ground, or fast country; being that part of the internal structure of the earth, which they find lying even, and in an orderly manner, and, evidently having retained its primitive form and situation, unmoved by the waters of the general deluge, while the circumjacent, and upper strata, have plainly been removed and tossed about.

SHELL, *Conchias*, in natural history, a hard, and, as it were stony covering, with which certain animals are defended, and thence called shell-fish.

*Fossile-SHELLS*, those found buried at great depths in earth, and often immersed in the hardest stones. These fossile shells, as well as those found lying on the sea-shore, make an excellent manure, especially for cold clayey lands; upon which it does not produce nearly so great an effect for the two first years, as it does in the succeeding ones; the reason of which is, that it is not then sufficiently mixed, but in succeeding time it breaks itself into a number of very small particles, and these all become intimately blended with the molecules of earth, and produce their effect more properly.

SHELTIE, a small but strong kind of horse, so called from Shetland, or Zetland, where they are produced.

SHEPHERD'S-NEEDLE, *Scandix*, in botany. See SCANDIX.

SHEPHERD'S-POUCH, *Bursa Pastoris*, in botany, an annual plant which grows naturally in many parts of England; the stalk rises to about a foot high, the lower leaves are sometimes whole, but more generally jagged; those that grow on the stalks are much less broad at their base, having even edges, and ending in a point; the flowers terminate the tops of the branches, they are small and cruciform, consisting each of four roundish petals, which are succeeded by a small heart-shaped fruit, or, as some fancy, like a purse, and is about a quarter of an inch long.

For its proper generical characters, see the article THLASPI, of which it is held a species. Its juice is very astringent and glutinous; it stops bleeding at the nose, is good against spitting of blood, and in diarrhoeas, dysenteries, and bloody urine. The dose, in infusion, is a handful; of the juice, four ounces; and of the powder of the dried leaves, a dram.

SHEPHERD'S-ROD, *Dipsacus*, in botany. See the article DIPSACUS.

SHERARDIA, in botany, a genus of plants, whose flower is monopetalous and funnel-shaped; the tube is long and cylindraceous, and the limb is divided into four plane acute segments; on the top of the tube are placed four filaments, topped with single antheræ: the fruit is oblong, coronated, and separable longitudinally into two oblong seeds.

This genus includes the clivers, or goosegrafs, which grows naturally in hedges: it is reckoned inciding and aperient; and not only promotes urine, but sweat. Two ounces of the juice have been found to be very serviceable in the dropsy, carrying off the water by urine.

SHERIFF, an officer in each county of England, nominated by the king, invested with a judicial and ministerial power, and who takes place of every nobleman in the county, during the time of his office. His judicial authority consists in hearing and determining causes in his county-court, and in keeping the peace of the county; he being by the common law

A First Rate Ship of War with Rigging &c.

W. H. R. 1792

law the principal conservator of the peace there : for which reason he is to assist the judges, and raise the posse comitatus when occasion requires ; and such persons, as on a hue-and-cry he shall apprehend upon suspicion of felony, he is to commit to prison ; he may also imprison any one who breaks the peace in his presence. The ministerial office of the sheriff consists in proclaiming statutes, and making returns of writs for electing knights of the shire, &c. He collects the king's rents, seizes the profits of lands forfeited, and the goods of felons ; levies the king's debts, fines, amercements, &c. and is accountable to the king for the profits of the county, on which account the sum of 4000 l. is set apart and annually allowed to the sheriffs of the several counties of England, to help them to pass their account, and to defray their expences at the assizes, &c. where no sheriff is obliged to keep a table for the entertainment of any persons but those of his own retinue ; neither is he to have above forty servants in livery, or less than twenty attending him. It is also his office to execute the writs and processes out of the king's court ; and no process is to be served but by the sheriff. He returns juries for trials, as well in civil as in criminal cases, except where there is cause of challenge against him, in which case they are to be returned by the coroner. And, lastly, the sheriff is to see that criminals are executed, and the order of law observed in putting them to death. A sheriff has usually under him an under-sheriff, bailiffs, and a gaoler, for all of whom he is answerable. An under-sheriff ought always to have his deputy in the courts of justice, in order to receive his commands, and give an account of business, &c. All returns made by the under-sheriff are in the name of the high-sheriff ; and for every default in the execution of his office, either by fraud or neglect, the high-sheriff is amercable in the exchequer. On the death of any sheriff, the under-sheriff shall officiate in his name, till another is appointed, and also be answerable, &c.

**SHIELD**, an ancient weapon of defence, in the form of a light buckler, borne on the arm, to turn off lances, darts, &c.

**SHIELD**, in heraldry, the escutcheon or field on which the bearings of coats of arms are placed. See **ESCUTCHEON**.

**SHILLING**, an English silver coin. See the article **COIN**.

It is observed, that there were no shillings or twelve-penny pieces in England till the year 1504, when they were first coined by Henry VIII.

**SHINGLES**, in building, small pieces of wood, or quartered oaken boards, sawn to a certain scantling, or, as is more usual, cleft to about an inch thick at one end, and made like wedges, four or five inches broad, and eight or nine inches long.

Shingles are also used instead of tiles or slates, especially for churches and steeples : however, this

covering is dear ; yet where tiles are very scarce, and a light covering is required, it is preferable to thatch ; and where they are made of good oak, cleft, and not sawed, and well seasoned in water and the sun, they make a sure, light, and durable covering.

The building is first to be covered all over with boards, and the shingles nailed upon them.

**SHINGLES**, in medicine, a kind of herpes. See **HERPES**.

**SHIP**, *Navis*, a general name for all large vessels with sails, fit for navigation on the sea ; except galleys, which go with oars and smack-sails. See **NAVIGATION**, **NAVAL ARCHITECTURE**, and **NAVY**.

A ship is undoubtedly the noblest machine that ever was invented ; and consists of so many parts, that it would require a whole volume to describe it minutely. However, we shall endeavour to satisfy the reader the more fully on this head, as it is in an article of the utmost importance, of which no gentleman should be ignorant : and first, to give an idea of the several parts and members of a ship, both external and internal, with their respective names in the sea language, in plate LXXXII. is represented a ship of war of the first rate, with rigging, &c. at anchor ; where A is the cat-head ; B, the fore-chains ; C, the main-chains ; D, the mizzen-chains ; E, the entering-port ; F, the hawse-holes ; G, the poop-lanterns ; H, the chess-tree ; I, the head ; K, the stern.

L, the bowsprit ; 1, 2, yard and sail ; 3, gammoning ; 4, horse ; 5, bob-stay ; 6, sprit-sail sheets ; 7, pendants ; 8, braces and pendants ; 9, halliards ; 10, lifts ; 11, clew-lines ; 12, sprit sail horses ; 13, bunt-lines ; 14, standing-lifts ; 15, sprit-sail-top ; 16, flying jib-boom ; 17, flying jib-stay and sail ; 18, halliards ; 19, sheets ; 20, horses.

M, the sprit-sail top-mast ; 21, shrouds ; 22, 23, yard and sail ; 24, sheet ; 25, lifts ; 26, braces and pendants ; 27, cap ; 28, jack-staff ; 29, truck ; 30, jack-flag.

N, the fore-mast ; 31, runner and tackle ; 32, 33, shrouds ; 34, laniards ; 35, stay and laniard ; 36, preventer-stay and laniard ; 37, wooding the mast ; 38, yard and sail ; 39, horses ; 40, top ; 41, crowfoot ; 42, jeers ; 43, yard-tackles ; 44, lifts ; 45, braces and pendants ; 46, sheets ; 47, fore-tacks ; 48, bow-lines and bridles ; 49, fore bunt-lines ; 50, fore-leech-lines ; 51, fore top-rope ; 52, puttock-shrouds.

O, the fore top-mast ; 53, 54, shrouds and laniards ; 55, yard and sail ; 56, stay and sail ; 57, runner ; 58, back-stays ; 59, halliards ; 60, lifts ; 61, braces and pendants ; 62, horses ; 63, clew-lines ; 64, bow-lines and bridles ; 65, reef-tackles ; 66, sheets ; 67, bunt-lines ; 68, cross-trees ; 69, cap.

P, the fore-top gallant-mast ; 70, 71, shrouds and laniards ; 72, yard and sail ; 73, back-stays ;

74, stay; 75, lifts; 76, clew-lines; 77, braces and pendants; 78, bow-lines and bridles; 79, flag-staff; 80, truck; 81, flag-staff-stay; 82, flag of lord high-admiral.

**Q**, the main-mast; 83, 84, shrouds; 85, laniards; 86, runner and tackle; 87, pendant of the gornet; 88, guy of ditto; 89, sail of ditto; 90, stay; 91, preventer-stay; 92, stay-tackle; 93, woolding the mast; 94, jeers; 95, yard-tackles; 96, lifts; 97, braces and pendants; 98, hordes; 99, sheets; 100, tacks; 101, bow-lines and bridles; 102, crow-foot; 103, top-rope; 104, top; 105, bunt-lines; 106, leech-lines; 107, yard and fail.

**R**, the main-top-mast; 108, 109, shrouds and laniards; 110, yard and fail; 111, puttock-shrouds; 112, back-stays; 113, stay; 114, stay-sail and stay and halliards; 115, runnets; 116, halliards; 117, lifts; 118, clew-lines; 119, braces and pendants; 120, hordes; 121, sheets; 122, bow lines and bridles; 123, bunt-lines; 124, reef-tackles; 125, cross-trees; 126, cap.

**S**, the main-top gallant-mast; 127, 128, shrouds and laniards; 129, yard and fail; 130, back-stays; 131, stay; 132, stay-sail and halliards; 133, lifts; 134, braces and pendants; 135, bow-lines and bridles; 136, clew-lines; 137, flag-staff; 138, truck; 139, flag-staff-stay; 140, flag-standard.

**T**, the mizzen-mast; 141, 142, shrouds and laniards; 143, pendants and burtons; 144, yard and fail; 145, crowfoot; 146, sheet; 147, pendant-lines; 148, peck-brails; 149, stay-sail; 150, stay; 151, derrick and spann; 152, top; 153, cross jack-yard; 154, cross jack-lifts; 155, cross jack-braces; 156, cross jack-slings.

**V**, the mizzen-top-mast; 157, 158, shrouds and laniards; 159, yard and fail; 160, back-stay; 161, stay; 162, halliards; 163, lifts; 164, braces and pendants; 165, bow-lines and bridles; 166, sheets; 167, clew-lines; 168, stay-sail; 169, cross-trees; 170, cap; 171, flag-staff; 172, flag-staff-stay; 173, truck; 174, flag-union; 175, ensign-staff; 176, truck; 177, ensign; 178, poop-ladder; 179, bower-cable.

Thus we have pointed out the external parts, masts, rigging, &c. an account of all which may be seen under their respective articles **MAST**, **HULL**, **ROPE**, **RUDDER**, &c.

**SHIVERS**, or **SHEEVERS**, in the sea language, names given to the little rollers or round wheels of pulleys. See **PULLEY**.

**SHOAD**, among miners, denotes a train of metalline stones, serving to direct them in the discovery of mines. See **MINE**.

**SHOAL**, in the sea language, denotes a place where the water is shallow.

**SHOAR**, or **SHORE**. See **SHORE**.

**SHOE for an Anchor**, in a ship, the place for the anchor to rest, and fitted to receive the stock, &c.

so as to prevent the sheets, tacks, and other running-rigging, from galling, or being entangled with the stocks.

**SHOOTING**. See the articles **GUNNERY** and **PROJECTILE**.

**SHORE**, or **SHOAR**, a place washed by the sea, or some large river.

**SHORT-SIGHTEDNESS**, *Myopia*, in medicine. See the article **MYOPIA**.

**SHOT**, a denomination given to all sorts of balls for fire-arms; those for cannon being of iron, and those for guns, pistols, &c. of lead.

*Indian-SHOT*, *Canna*, in botany. See the article **CANNA**.

**SHOVELER**, in ornithology, a species of the anas, with the extremity of the beak broad and round, and its unguis bent. See **ANAS**.

**SHOULDER-BONE**, *Humerus*, in anatomy. See the article **HUMERUS**.

**SHOULDER-BLADE**, *Scapula*. See the article **SCAPULA**.

**SHOULDER-PITCHED**, among farriers, is said of a horse whose shoulder is displaced, which may be remedied by swimming the horse a dozen times up and down in deep water.

**SHOULDER-SPLAIT**, is when a horse's shoulder is parted from the breast.

**SHOULDERING PIECE**, among builders, the same with a bracket. See the article **BRACKET**.

**SHOWER**, in meteorology, a cloud resolving into rain. See the article **RAIN**.

**SHRIMP**, in ichthyology, the English name of two different species of the squilla, viz. the common shrimp, and the smooth-nosed shrimp.

The common shrimp is the long-tailed squilla, with the snout ferrated above and tridentated below; the body is oblong and rounded above the beak or snout; which distinguishes it from all the other species: it is long, of a lanceolated figure, sharp-pointed, and has eight denticulations above, and three below. The smooth-nosed shrimp, or long-tailed squilla, with a smooth snout, grows to the same size with the common shrimp; however, the body is thick, and the snout is very short, without the spines or denticulations of the other.

**SHRINE**, in ecclesiastical history, a case or box, to hold the relics of some saint. See the articles **RELICS** and **SAINT**.

**SHRITE**, in ornithology, the same with the missel-bird.

**SHROVE-TUESDAY**, is the Tuesday after quinquagesima Sunday, or the day immediately preceding the first of lent; being so called from the Saxon word *shrove*, which signifies *to confess*, as having been employed by the people, in time of popery, in confessing their sins, in order to receive the sacrament, and thereby qualify themselves for a more religious observation of Lent. See the article **LENT**.

In process of time this custom was changed into that of mutual invitations, in order to take leave of flesh-meat and other dainties; and this made way for sports and other merriments, which at present make up the whole business of the carnival, or season immediately preceding Lent. See the article **CARNIVAL**.

**SHROWDING** of *Trees*, the cutting or lopping off their top branches, which is practised only on trees not fit for timber, and designed to yield a present advantage, and serve for fuel.

Trees should be three or four years old before they are shrouded, which should be done in winter for the harder sorts of wood, and in spring for the softer kinds, taking care to cut the remaining stump aslope and smooth.

**SHROWDS**, or **SHROUDS**, in a ship, are the great ropes which come down both sides of the masts, and are fastened below to the chains on the ship's side, and aloft to the top of the mast; being parcelled and served, in order to prevent the mast's galling them. The top-mast-shrouds are fastened to the puttock-plates, by dead-eyes and laniards, as the others are. See the article **SHIP**.

**SHRUB**, *Frutex*, among botanists, a dwarf plant of a woody contexture, being between a tree and an herb; such are the box, rose, privet, laurustinus, syringa, &c. It is difficult to determine the difference or boundary between trees and shrubs, to say where one ends and the other begins; the best definition which can be made of a shrub, to distinguish it from a tree, is its sending forth many stems from the roots; whereas trees have a single trunk or body.

**SHUTTLE**, in the manufactures, an instrument much used by weavers, in the middle of which is an eye, or cavity, wherein is inclosed the spool with the woof.

**SI**, in music, a seventh note or sound, added by Le Maire to the six ancient tones invented by Guido Aretine, viz. *ut, re, mi, fa, sol, la, si*. See the articles **GAMUT**, **SCALE**, and **SOLFAING**.

**SIBBALDIA**, in botany, a genus of plants, the flower of which consists of five oval petals inserted into the cup; the stamina are five capillary filaments, topped with small obtuse antheræ; there is no pericarpium, but the cup contains five oblong seeds, which closes for that purpose.

**SIBTHORPIA**, in botany, a genus of plants, whose flower is monopetalous, and divided into five equal patent segments; it contains four hairy filaments, topped with oblong, heart-shaped antheræ: the fruit is an orbicular, compressed, bilocular capsule, containing a few roundish oblong seeds, which are convex on one side, and flat on the other.

**SIBYLS**, *Sibyllæ*, in Pagan antiquity, certain women said to have been endowed with a prophetic spirit, and to have delivered oracles, fore-shewing the fates and revolutions of kingdoms, &c.

**SICILIAN**, in music, a kind of air or dance, in triple time, and played slow, notwithstanding it is marked the same as a jig.

**SICYOS**, in botany, a genus of plants, producing male and female flowers, which are campanulated, and divided into five segments; the fruit is an ovate berry, beset with spines, and containing one cell, which incloses a single seed of the same shape. This genus is the same with the *sicyoides* of Tournefort, and the *bryonoides* of Dillenius.

**SIDA**, Indian mallow, in botany, a genus of plants, whose flower is pentapetalous, broad, and emarginated, containing a number of stamina, which coalesce at their bottoms: the fruit is a roundish, acuminate capsule, with five cells, each containing a roundish seed, convex on one side, and angular on the other.

This genus comprehends the *malvina* of Dillenius, and the *abutylon* of Tournefort.

**SIDES-MEN**, or **SYNOD'S-MEN**, persons who, in large parishes, are appointed to assist the church-wardens, in their enquiry and presentments of such offenders to the ordinary, as are punishable in the spiritual court.

**SIDERATION**, a term used for a sphacelus or mortification. See **SPHACELUS**.

Some also use the term *sideration* for the blasting or blighting of trees. See the articles **BLIGHT** and **TREE**.

**SIDEREAL YEAR**. See **YEAR**.

**SIDERITES**, in natural history, the same with the magnet. See **MAGNET**.

**SIDERITIS**, iron-wort, in botany, a genus of didynamious plants, whose flower is monopetalous and ringent; the upper-lip is erect, narrow, and bifid, and the lower one trifid; there is no pericarpium, but the cup contains in its bottom four seeds.

Iron-wort is accounted vulnerary and astringent, and has been recommended to cure ruptures. The Germans make use of it in baths, to open the pores of the skin, which it is said to do very powerfully.

**SIDEROXYLUM**, iron-wood, in botany, a genus of plants, whose flower is monopetalous and rotated; the filaments are five, and terminated with oblong incumbent antheræ: the fruit is a roundish, unilocular drupe, containing four seeds. This genus are natives of the Cape of Good-Hope, and obtained the name of iron-wood among the inhabitants on account of its close contexture, and being so heavy as to sink in water.

**SIEGE**, in the art of war, the encampment of an army before a fortified place, with a design to take it.

**SIGESBECKIA**, in botany, a genus of plants, whose flower is compound and radiated, the disk is composed of a number of hermaphrodite florets, and the rays are formed of a few ligulated female ones: the seeds are solitary, oblong, and obtusely trigonal,

nal, without any down, and placed on a paleaceous receptacle.

**SIGHT**, or **VISION**, in optics. See the articles **EYE** and **VISION**.

**SIGHTS of a Quadrant, &c.** thin pieces of brass, raised perpendicularly on its side, or on the index of a theodolite, circumferentor, &c. They have each an aperture, or slit, up the middle, through which the visual rays pass to the eye, and distant objects are seen.

**SIGN**, *Signum*, in general, the mark or character of something absent or invisible.

**SIGN**, in astronomy, a constellation containing a twelfth part of the zodiac, or 30°. See the article **ZODIAC**.

The names of the signs, in the order wherein they follow each other, are, aries, taurus, gemini, cancer, leo, virgo, libra, scorpio, sagittarius, capricornus, aquarius, pisces. See the articles, **ARIES**, **TAURUS**, **GEMINI**, &c.

**SIGN-MANUAL**, in law, is used to signify any bill, or writing, signed by the king's own hand.

**SIGNALS**, certain signs agreed upon, for suddenly conveying intelligence to places, to which the voice cannot reach. Thus, in some countries fires are lighted upon the hills, at the approach of danger: and at the beginning of a battle or an attack, signals are usually made with drums and trumpets. At sea they are given by firing cannon, or musquets; by lights, flags, sails, &c.

Signals at sea are made by the admiral or commander in chief of a squadron, either in the day, or by night, whether for sailing, fighting, or the better security of the merchant-ships under their convoy: these are very numerous and important, being all appointed and determined by the lords of the admiralty, and communicated in the instructions sent to the commander of every ship of the fleet or squadron, before their putting to sea.

**SIGNATURE**, a signing of a person's name at the bottom of an act or deed, wrote by his own hand.

**SIGNATURE**, in printing, is a letter put at the bottom of the first page at least, as a direction to the binder, in folding, gathering, and collating them.

**SIGNET**, one of the king's seals, made use of in sealing his private letters, and all grants that pass by bill signed under his majesty's hand: it is always in the custody of the secretaries of state.

**SILENE**, in botany, a genus of plants, whose flower is pentapetalous; the ungues are narrow, the length of the cup; and the limb is obtuse and plane; the nectarium is compounded of two small indentures in the neck of each petal, constituting a crown to the chaps; the stamina are ten subulated filaments, topped with oblong antheræ: the fruit is a close cylindrical trilocular capsule, opening at the top five ways, and containing a number of

kidney-shaped seeds. A species of this genus is cultivated in gardens, and is called by the gardeners, Lobel's catchfly.

**SILER**, in botany, a species of laserpitium. See the article **LASERPITIUM**.

**SILIQUEA**, a pod, among botanists. See the article **POD**.

**SILIQUEA** is also a name by which Tournefort calls the ceratonia of Linnæus. See the article **CERATONIA**.

**SILICUASTRUM**, in botany, Tournefort's name for the cercis of Linnæus. See the article **CERCIS**.

**SILIQUEOSE-PLANTS**, those which produce pods; such are the cabbage, mustard, stock, &c.

**SILK**, *Sericum*, in natural history, is properly an animal fluid, hardened by the air; being an extremely soft and glossy thread, spun by the bombyx or silk-worm, the body of which consists of eleven rings: it produces a species of phalænæ, or moths, with pectinated wings, but no tongue.

The humours, found in the body of this insect, approach to the nature of silk; since, on being rubbed in the hand, they leave a solid crust behind. In the sides of the belly, all about the ventricle, there are deposited a vast number of vessels, which contain the silky juice; these run with various windings and meanders to the mouth, and are so disposed, that the creatures can discharge their contents at pleasure at the mouth; and according to the nature of the juices that they are supplied with, furnish different sorts of silk from them; all the fluid contents of these vessels hardening in the air into that sort of thread, that we find the web, or balls of this creature consist of.

As soon as the silk-worm is arrived at the size and strength necessary for beginning his cod, he makes his web; for it is thus they call that flight tissue, which is the beginning and ground of this admirable work. This is his first day's employment. On the second, he forms his folliculus, or ball, and covers himself almost over with silk. The third day he is quite hid, and the following days employs himself in thickening and strengthening his ball, always working from one single end, which he never breaks by his own fault, and which is so fine, and so long, that those who have examined it attentively, think they speak within compass when they affirm, that each ball contains silk enough to reach the length of six English miles.

In ten days time the ball is in its perfection, and is now to be taken down from the branches of the mulberry-tree, where the worms have hung it. But this point requires a deal of attention; for there are some worms more lazy than others, and it is very dangerous waiting till they make themselves a passage, which usually happens about the fifteenth day.

The first, finest, and strongest balls are kept for the

the grain, the rest are carefully wound; or if it is desired to keep them ail, or if there be more than can be well wound at once, they lay them for some time in an oven moderately hot, or else expose them, for several days successively, to the greatest heats of the sun, in order to kill the insect, which, without this precaution, would not fail to open itself a way to go, and use those new wings abroad, it had acquired within.

Ordinarily, they only wind the more perfect balls; those that are double, or too weak, or too coarse, are laid aside, not as altogether useless, but that, being improper for winding, they are reserved to be drawn out into skains.

The balls are of different colours; the most common are yellow, orange-colour, Isabella, and flesh-colour; there are some also of a sea-green, others of a sulphur-colour, and others white; but there is no necessity for separating the colours and shades to wind them apart, as all the colours are to be lost in the future scouring and preparing of the silk.

In the Philosophical Transactions, N<sup>o</sup>. 252, we find the following observations concerning the goodness of silk, which is best distinguished by its lightness. The organzine silk is the best of any made in the country of Piedmont, and two threads are equal in fineness, that is in smoothness, thickness, and length, for the thread of the first twist. For the second, it matters not whether the single thread be strong before the two are joined, unless to see whether the first twist prove well.

It is necessary that the silk be clean; and it is to be observed, that the straw-coloured is generally the lightest, and the white the heaviest of all. The skains should be even, and all of an equality, which shews that they were wrought together; otherwise we may with justice suspect that it is refuse silk, and cannot be equally drawn out and spun, for one thread will be shorter than the other, which is labour and loss.

It will also be requisite to search the bale more than once, and take from out of the parcels a skain to make an essay; for unless it be known by trial what one buys, there is the greatest danger of being cheated in this commodity. To make an estimate, and know the lightness, fix the essay upon one-eighth of a portée, or hand of silk of 110 aunes or ells of Lyons in length, and see what it makes of aunes by the eighth part. The skain, which is of 80 threads, must be multiplied by 110 aunes of Lyons, and from this number must be deducted one-eighth; as for example, 110 by 80 makes 8800, the eighth part of which is 1100; and this is the eighth part of a portée, or hand of silk. Now, to calculate what these 1100 aunes weigh, which is the eighth part of a portée, or of 110 aunes of Lyons, it will be proper to take a skain out of the parcels, which you take from out of the bale which you judge may contain, at least, 1100 aunes, to make the one-

eighth part of a portée, which portée must be divided on two bobbins, half on each; then fix the two bobbins on the center, or beam, and from thence pass it through the comb hurdissoir, viz. 550 from the two bobbins, will make 1100, which will be one-eighth part of what you desire to know. This done, you cut off your silk, and carry it to put on the hurdissoir; then weigh it, and multiply the weight by eight, it will weigh just as much as a portée of 110 aunes of Lyons, which is the general rule for calculating. When they draw the silk out by this means, one may learn to adjust the weight.

There are silks of Piedmont, which are very light and clean, and are to be preferred before any on the sale; the portée of silk of the lightest, weighs near twenty-four penny-weights, and from this it arises in gravity to twenty-five, and twenty-six penny-weights the portée, and sometimes to twenty-seven and twenty-eight; but even these weights may be dispensed with, provided that the other qualities be good, that is, that it be well wrought, even, and clean. When the silk is more than twenty-eight penny-weights the portée, it must always be proportionably cheaper.

*Methods of preparing SILKS.*—The several preparations which silks undergo to fit them to be used in the manufacture of silken stuffs, are reeling, spinning, milling, bleaching, and dyeing.

To wind silks from off the balls, two machines are necessary; the one a furnace, with its copper; the other a reel, or frame, to draw the silk. The winder, then seated near the furnace, throws into the copper of water over the furnace (first heated and boiled to a certain degree, which custom alone can teach) a handful or two of balls, which have been first well purged of all their loose furry substance. She then stirs the whole very briskly about with birchen rods, bound and cut like brushes; and when the heat and agitation have detached the ends of the silks of the pods, which are apt to catch on the rods, she draws them forth, and joining ten or twelve, or even fourteen of them together, she forms them into threads, according to the bigness required to the works they are destined for: eight ends sufficing for ribbands; and velvets, &c. requiring no less than fourteen. The ends thus joined into two or three threads, are first passed into the holes of three iron rods, in the fore part of the reel, then upon the bobbins, or pullies, and at last are drawn out to the reel itself, and there fastened, each to an end of an arm or branch of the reel. Thus disposed, the winder, giving motion to the reel, by turning the handle, guides the threads; substitutes new ones, when any of them break, or any of the balls are wound out; strengthens them, where necessary, by adding others; and takes away the balls wound out, or that, having been pierced, are full of water. See plate LXXXIII. fig. 1.

In this manner, two persons will spin and reel three pounds of silk in a day; which is done with greater dispatch than is made by the spinning-wheel or distaff. Indeed, all silks cannot be spun and reeled after this manner; either by reason the balls have been perforated by the silk-worms themselves, or because they are double, or too weak to bear the water; or because they are coarse, &c. Of all these together, they make a particular kind of silk, called *floretta*, which being carded, or even spun on the distaff, or the wheel, in the condition it comes from the ball, makes a tolerable silk.

As to the balls, after opening them with scissars, and taking out the insects (which are of some use for the feeding of poultry) they are steeped three or four days in troughs, the water whereof is changed every day to prevent their sinking. When they are well softened by this scouring, and cleared of that gummy matter the worm had lined the inside withal, and which renders it impenetrable to the water, and even to air itself, they boil them half an hour in a ley of ashes very clear and well strained: and after washing them out in the river, and drying them in the sun, they card and spin them on the wheel, &c. and thus make another kind of *floretta*, somewhat inferior to the former.

As to the spinning and reeling of raw silks off the balls, such as they are brought from Italy and the Levant, the first is chiefly performed on the spinning-wheel; and the latter, either on hand-reels, or on reels mounted on machines, which serve to reel several skains at the same time. See the article *REEL*.

As to the milling, they use a mill composed of several pieces, which may mill two or three hundred bobbins at once, and make them into as many skains.

*Spider-SILK*, that prepared of the webs of spiders; which, according to Reaumur, is inferior to that obtained from the bags of the silk-worm, both in strength and lustre.

*SILLON*, in fortification, the same with envelope. See the article *ENVELOPE*.

*SILPHIUM*, in botany, a genus of plants, whose flower is compound and radiated, containing a great number of hermaphrodite funnel-shaped florets, which form the disc, and a few female corollulæ, which are very long, spear-shaped, and tridentated, which compose the rays; the hermaphrodite florets are barren, but the female produce solitary, membranaceous, cordated seeds, which are placed on a paleaceous receptacle, and contained in the cup.

The species of this genus are natives of America, and includes the asteriscus of Dillenius.

*SILVER*, *Argentum*, ☿, in natural history, the purest and most fixed of all metals, except gold.

Silver, though frequently found native and pure, is however often found in the state of ore; as among the grey ores of copper, the ore of lead, of cobalt,

antimony, and other mineral bodies. The proper and peculiar ores of silver are of various appearances; as in that of a soft substance of a blackish-blue colour, greatly resembling lead: another ore of silver is in form of brown or brownish-yellow obscurely transparent masses, not a little resembling the coarser sorts of amber: there is another silver-ore of a very bright and beautiful red, a smooth even surface, and considerably pellucid, resembling very much native sandarach. These are the more usual and determinate ores of silver, which in many of the German mines are blended all together, sometimes with the black kind wholly covering the red: the black kind is often soft enough to be cut with a knife.

The method of precipitating silver out of an easily fusible ore is this; pound the ore very fine in an iron mortar, and for an assay weigh one docimastical centner of it, and eight centners of granulated lead; pour into a new test about half the lead, stir it about with a finger, and spread it over the cavity of the test; put upon this lead the pounded ore, and then cover it with the remainder of the lead; put the test, thus loaded, under the muffle of an assay-furnace, and in the hinder part of it make the fire, and encrease it to a considerable high degree. The ore will soon be raised out of the melted lead, and swim upon it; a little after, it will grow clammy, melt, and be thrown toward the border of the test; then the surface of the lead will appear clear in the middle of the test, and will smooke and boil; the fire must now be made a little less, till the boiling ceases, for a quarter of an hour, and then made violent again, and the surface of the lead will then diminish by degrees, and be covered with a mass of scorix. At this time have at hand an iron hook ready heated, and with this stir all the matter from the sides into the middle of the test; if the matter, adhering to the hook from the stirring, melts quickly again, and the extremity of the hook, when cold, is found covered with a shining crust, the scorification is perfected; but if the scorix feel clammy while stirred, and adhere in quantity to the hook, and are of a rough surface, the scorification is not perfect, but the matter adhering to the hook must be struck off with a hammer, and beat to powder, and returned into the test, and the fire continued till the scorification is perfected; then take out the test, and pour the whole contents into a mould, heated and greased. This is the first process, and this usually takes up three quarters of an hour: the silver is now in form of a regulus, and must be separated by the coppel in the usual way.

When silver-ores are rendered refractory by an admixture of mundic, they must be pounded and put into a covered test, which is to be placed in an assay-furnace under a muffle, till all the mundic is evaporated; which you may know by the cessation of the smoke from the ore: let this roasted ore cool leisurely;

leisurely; then powder it fine, and mix it with an equal quantity of glass of lead reduced likewise to fine powder; and, lastly, scorify the whole till the silver appear in the form of a bright bead in the middle of the test.

When the silver is well purified, so that all heterogeneous matter, either metallic or other, that might be mixed with it, is extracted, they say it is twelve carats fine. This is the expression they use to denote the quality of the purest silver, without any mixture or alloy; but, if there should remain any, they deduct the weight of the mixture from the principal weight, and the remainder shews the value of the silver. The carat consists of twenty-four grains: so that, when to the weight of twelve carats there are twelve grains of mixture, the value of the silver is eleven carats twelve grains; and so of any other.

Silver, though considerably hard in comparison of lead or gold, is yet malleable and ductile to a very great degree, and may be drawn out into an extremely fine wire. It is less capable of rust than any other metal, except gold; but it readily becomes black on being rubbed with sulphur. It requires a middle degree of fire to fuse it; bearing unaltered a stronger degree of heat than either lead or gold, but melting much more easily than copper or iron. It, indeed, grows red-hot, but then melts immediately. It amalgamates readily enough with mercury; the readiest way of mixing them is to have the silver in fine filings, very clear from grease, and to rub it in a mortar with the mercury. It is fixed in a common fire, so as to lose scarce any thing; and perhaps, truly speaking, not any thing at all, in the fiercest degree of it, if ever so long continued: it has been tried by Boerhaave for two months together, in the eye of a glass-house furnace, and found to lose only one twelfth part of its weight in the operation; and it is highly probable, that even this loss might be owing to the silver's not being perfectly purified at first.

Silver, exposed to the fiercest fire, collected in the focus of a large burning-glass, immediately becomes red-hot, melts, and emits a thick smoke: soon after this, it is covered with a dusty substance, or calx. If the silver have been refined by means of antimony, the calx is of a yellowish hue, and, if kept long enough in the focus, it will vitrify in the same manner as gold; but, if it have been refined with lead, the calx is whiter, and, Homberg assures us, will never vitrify, however long exposed, even to that degree of heat.

Silver is purified by means of lead, and bears its action without loss. Fused with antimony, if the effect be not carefully prevented, it turns to scoria, and becomes volatile: there is no metal, indeed, except gold alone, that bears the test with this rapacious mineral, in the common way. See the article GOLD.

The proper solvent of silver is aqua fortis; it is dissolved readily by this, and not at all by the common aqua regia; yet, under certain circumstances, aqua regia will dissolve silver: the first phlegm which arises in distilling that menstruum, when newly made, and when it has been some time in digestion with gold, will dissolve silver, and will not touch gold; though it cannot but be acknowledged, this liquor is as much aqua regia, as what follows in the distillation. This, however, is an experiment of mere curiosity, not likely ever to occur in the way of business, and in that respect, though we are acquainted with this accident, which was casually discovered by Homberg, we may say in general, that aqua fortis dissolves silver, and not gold; and aqua regia gold, and not silver. If but the smallest quantity of sea-salt be put into aqua fortis, it will no longer give a clear solution of silver. This gives us a test for the goodness of aqua fortis: and to this difference in the effect of these two menstrua we owe the only method of separating silver from gold, without loss. If silver be fused with lead, it loses its sound, and its bright colour; if melted with tin, it becomes extremely brittle, and the two metals are very difficultly separated again. It melts and mixes easily with copper, and by that means acquires a hardness which fits it for our coins and utensils, much better than in its pure natural state.

*Refining of SILVER.* See the article REFINING.

**SILVER-LEAF**, that beaten out into fine leaves for the use of the gilders, which is performed in the same manner as gold-leaf.

**SILVER-WIRE**, that drawn out into fine wire.

**Shell-SILVER**, is prepared of the shreds of silver-leaves, or of the leaves themselves, for the use of painters, after the same manner as shell-gold.

**SILVER-BUSH**, *Anthyllis*, in botany, a shrub which often grows ten or twelve feet high, and divides into many lateral branches, which are furnished with winged leaves, that are very white and hairy; the flowers are produced in small heads at the extremity of the branches; they are of a bright yellow colour, appearing in June; and are succeeded by short woolly pods containing two or three kidney-shaped seeds. This plant is propagated by cuttings, which may be planted any time in the summer.

**SILVER-TREE**, *Protea*, in botany, a genus of plants, whose general corolla is uniform and a little longer than the cup, which is imbricated and scaly; the proper corolla is monopetalous, with a smooth, spreading, quadrifid limb, and contains four setaceous filaments, terminated with incumbent anthers; there is no pericarpium, but the seeds, which are solitary, roundish, and naked, are contained in the cup.

The species of this genus are natives of the Cape of Good Hope, and are noticed for the beauty of their shining silvery leaves; but, being somewhat tender,

tender, they require a green-house, to preserve them in winter.

**SILVER-WEED**, in botany, a species of potentilla. See the article **POTENTILLA**.

**SILVERING**, the covering any thing with silver. It is usual to silver metals, wood, paper, &c. which is performed either with fire, oil, or size. Metal-gilders silver by the fire: painter-gilders all the other ways. See **GILDING**.

To silver copper or brass: 1. Cleanse the metal with aqua-fortis, by washing it lightly, and immediately throwing it into fair water; or by heating it red-hot, and scouring it with salt and tartar, and fair water, with a small wire brush. 2. Dissolve some silver in aqua-fortis, in a broad-bottomed glass vessel, or of glazed earth, then evaporate away the aqua-fortis over a chaffing-dish of coals. 3. Put five or six times its quantity of water, or as much as will be necessary to dissolve it perfectly, on the remaining dry calx; evaporate this water with the like heat; then put more fresh water, and evaporate again; and if need be, the third time, making the fire towards the latter end so strong, as to leave the calx perfectly dry, which, if your silver is good, will be of a pure white. 4. Take of this calx, common salt, crystal of tartar, of each a like quantity, or bulk, and mixing well the whole composition, put the metal into fair water, and take of the said powder with your wet fingers, and rub it well on, till you find every little cavity of the metal sufficiently silvered over. 5. If you would have it richly done, you must rub on more of the powder, and in the last place wash the silvered metal in fair water, and rub it hard with a dry cloth.

**SILVERING of Glasses**. See the article **FOLIATING of Looking Glasses**.

**SIMATIUM**, or **SIMAISE**, in architecture. See the article **CYMATIUM**.

**SIMILAR BODIES**, in natural philosophy, are such as have their particles of the same kind and nature with one another.

**SIMILAR FIGURES**, in geometry, such as have their angles respectively equal, and the sides, about the equal angles, proportional. See the articles **RECTANGLE**, **TRIANGLE**, and **POLYGON**.

**SIMILE**, or **SIMILITUDE**, in rhetoric, a comparison of two things, which though different in other respects, yet agree in some one. The difference between a simile and comparison, is said to consist in this, that the simile properly belongs to whatever we call the quality of the thing, and the comparison to the quantity.

**SIMILITUDE**, in arithmetic, geometry, &c. denotes the relation of two things similar to each other.

**SIMONICAL** is applied to any person guilty of simony. See **SIMONY**.

**SIMONIANS**, in church history, a sect of ancient heretics, so called from their founder, Simon

Magus, or the magician. The heresies of Simon Magus were principally his pretending to be the great power of God, and thinking that the gifts of the Holy Ghost were venal, and to be purchased with money. He is said to have invented the Æons, which were so many persons of whom the Godhead was composed. His concubine Helen, he called the first intelligence, and mother of all things; and sometimes he called her Minerva, and himself Jupiter. Simon Magus gained a great many proselytes, who paid himself and his concubine divine worship; these were the earliest heretics, and those that St. John, St. Peter and St. Paul, in their epistles, so often warn the Christians against.

**SIMONY**, in ecclesiastical law, the crime of buying or selling spiritual gifts or preferments.

**SIMPLE**, *Simplex*, something not mixed or compounded, in which sense it stands opposed to compounded.

**SIMPLE**, in pharmacy, a general name given to all herbs or plants, as having each its particular virtue, whereby it becomes a simple remedy.

**SIN**, a breach or transgression of some divine law, or command.

**SINAPIS**, mustard, in botany, a genus of plants, whose flower is tetrapetalous and cruciform, containing four ovate nectariferous glandules, with six erect subulated filaments, two of which are the length of the cup, and the others longer; these are topped with spreading acuminate antheræ: the fruit is an oblong rough pod, having two cells which contain a number of globose seeds.

The common use of mustard is known to every one, and is very proper for people of a cold constitution, because it creates an appetite, helps digestion, and attenuates food; the seeds are stomachic, diaphoretic, antiscorbutic, and are good in hypochondriac diseases, as well as in sleepy disorders: the powder of them taken in white wine is excellent against the scurvy; and some affirm it will cure a quartan ague, if taken in hot wine two hours before the fit. The white mustard is used as a salad herb, especially in winter and spring.

**SINAPISM**, in pharmacy, an external medicine in form of a cataplasm, composed chiefly of mustard-seed pulverized, and mixed with the pulp of figs, or with briony, garlic, onion, or the like. See the preceding article.

**SINAPISTRUM**, in botany, the same with the cleome. See **CLEOME**.

**SINCIPUT**, in anatomy, the fore-part of the head, reaching from the forehead to the coronal suture.

**SINDON**, in surgery, a little round piece of linen silk, or lint, used in dressing a wound after trepanning.

**SINE**, or *right SINE of an Arch*, in trigonometry, is a right line drawn from one end of that arch, perpendicular to the radius drawn to the other end

of the arch; being always equal to half the chord of twice the arch.

**SINE-CURES**, ecclesiastical benefices without cure of souls.

**SINEW**, denotes what we properly call a nerve, though in common speech, it is rather used for a tendon. See the articles **NERVE** and **TENDON**.

**SINGING**, the action of making divers inflexions of the voice, agreeable to the ear, and correspondent to the notes of a song, or piece of melody.

The first thing to be done in learning to sing, is to raise a scale of notes by tones and semi-tones to an octave, and descend by the same notes; and then to rise and fall by greater intervals, as a third, fourth, fifth, &c. and to do all this by notes of different pitch. Then these notes are represented by lines and spaces, to which the syllables *fa*, *so*, *la*, *mi*, are applied, and the pupil taught to name each line and space thereby; whence this practice is called *sol-fa-ing*.

**SINGULAR NUMBER**, in grammar, that number of nouns and verbs which stands opposed to plural; and is used when we only speak of a single, or one, person, or thing.

**SINISTER**, something on, or towards, the left hand: finister is also used, among us, for unlucky, though in the sacred rites of divination, the Romans frequently used it in an opposite sense.

**SINISTRI**, a sect of ancient heretics, thus called, because they held the left hand in abhorrence, and made it a point of religion never to receive any thing therewith.

**SINKING FUND**, a provision made by the parliament, consisting of the surplussage of other funds, intended to be appropriated to the payment of the national debts; on the credit of which, very large sums have been borrowed for public uses.

**SINET**, on board a ship, a line or string made of rope-yarn, consisting generally of two, six, or nine strings, which are divided into three parts, and are plaited over one another, and then beaten smooth and flat with a wooden mallet.

**SINUATED LEAF**, in botany, a leaf which has a number of sinuses on its side, but those separated by lobes, not very long, nor themselves indented, or notched at the edges.

**Sinuato-dentated leaf**, expresses a leaf like the former, but with the lateral lobes of a linear figure.

**SINUS**, in anatomy, denotes a cavity in certain bones, and other parts, the entrance whereof is very narrow, and the bottom wider and more spacious.

**SINUS**, in surgery, a little cavity, or sacculus, frequently formed by a wound or ulcer, where pus is collected.

**SIPHON**, or **SYPHON**, in hydraulics, a bended pipe, one end of which being put into a vessel of liquor, and the other hanging out of the said vessel over another, the liquor will run out from the first

into the last, after the air has been sucked out of the external or lower end of the siphon, and that as long as the liquor in the upper vessel is above the upper orifice of the siphon.

Thus, **HDS** (plate **LXXXIII**. fig. 2.) is a siphon, whose two parts **HD**, **DS**, are called its legs, and by its operation, the water is drawn out of the upper vessel **ABCD**, into the lower *ab*. When you have sucked out the air at **S**, the water follows, coming in at **H**, going in the direction **HGDS**, and out at **S**, as long as the surface **EF** is above **IH**; the level of the mouth of what is called the driving leg of the siphon, being that in which the water goes up, as that through which it goes down is called the issuing leg, and is always longer than the driving leg.

Now, the cause of the siphon's running is this: The air which presses into the vessel **ABCD**, represented by the column **KL**, sustains the column of water **LD**, in the short leg of the siphon, pressing against that air with its perpendicular height **DF**, whilst the column of air **MS**, pressing upwards against the hole of the long or issuing leg **DS** (which acts according to the height **DC**) must yield and suffer the water to run out as long as the leg **DS** is longer, or rather higher in perpendicular than **DG**. For since **K** and **M** are supposed at top of the atmosphere, the column **KL** and **MS** are equal in height and pressure (the height of **L** above **S** being of no account in the height of the atmosphere) as long as **MS** is acted upon by the descending water **DS**, whose height is from **D** to **S** (suppose fifteen inches) an height superior to that of the column **DG** (suppose of seven inches) supported by the column of air **KL**, the column **MS** must yield to the water issuing out at **S**; and however the surface of the water **EF** descends, the column **KL**, by its pressure will always overcome the resistance of the column **MS**, because it has a less height of water to sustain than **MS** has.

If the mouth of the issuing leg had been at **T**, the water would hang in equilibrio, filling both legs of the siphon, when the water is come down in the upper vessel to **IHT**, because then the two columns of air **KL** and **MS** will be acted against by an equal height of water in the legs of the siphon; but if then you raise the issuing end of the siphon, now supposed at **T**, up to the level of *uV* above **IH**, the water will run back up from **V** to **D**, and so out at **H**, in the upper vessel, because then the column **MS** having only the height **VD** to sustain, will be acted against with less force than the column **KL**, which is pressed against by the whole height **DH**, superior to **VD**. See the articles **FLUID**, **ENGINE**, **AIR**, &c.

Since the pressure of the air is the cause of the water being pushed up into the siphon, and the difference of its pressure (as one column is acted against by the water in the short leg more weakly than

than another column of air is acted upon by the water in the long leg) is the cause of its running continually from one vessel into another, when once set going, it follows, that the bend D of the upper part of the siphon must not be above thirty-two feet higher than the water in the upper vessel, because the air cannot sustain a column of water whose height exceeds thirty-two feet.

If, therefore, there was a crane, or siphon, ACEDB (fig. 3.) of about forty feet high, reckoning from A to E, with cocks A and B at its lower ends, and a hole at the top E, to be stopped with a cork upon occasion, there might be made the following experiment :

Water being poured into the vessels A and B, let the cocks A and B be shut, then with a funnel, pouring in water at E, till both legs of the siphon are full, stop the hole E, and open the two cocks at once. The water, instead of running from the vessel A into B, which it would do if the height CA was much under thirty-two feet, will in the two legs fall back to C and D thirty-two feet above A and B, where it will hang, the air not being able to sustain the water above those heights, and consequently to drive it up over the bend E. Nay, unless the water be purged of air before the experiment, the top of the water at C and D will not be quite thirty feet above the water in the vessels A and B, because air will extricate itself out of the water, and getting into the cavity CED, press a little on the top of the water at C and D, so that its height will be less to balance the pressure of the atmosphere.

**SIPHONANTHUS**, in botany, a genus of plants, the flower of which is monopetalous and funnel-shaped; the tube is slender and very narrow, and the limb is cut into four segments: the fruit consists of four roundish berries, within a patulous cup, each containing a roundish seed.

**SIREN**, *σείρη*, in antiquity, a kind of fabulous animal, otherwise called a mermaid.

**SIRIUS**, the dog-star, in astronomy, a very bright star of the first magnitude, in the mouth of the constellation canis major. See the articles CANICULA and CANIS.

**SIRNAME**. See the article SURNAME.

**SISARUM**, in botany, the same with sium. See the article SIUM.

**SISON**, corn-parsley, in botany, a genus of umbelliferous plants, the general corolla of which is uniform, each proper one consists of five equal, inflexed, lanceolated petals, with five capillary stamina: there is no pericarpium, but the fruit, which is oval and furrowed, divides into two ovate seeds, convex and striated on one side, and flat on the other.

The seeds belonging to a species of this genus are one of the lesser hot seeds of the shops, and have an aromatic smell and taste; they are attenuant, aperient, and carminative: they are prescribed in fla-

tulencies and cholics, and are said to be a lithontriptic.

**SISTRUM**, or **CISTRUM**, a kind of ancient musical instrument, used by the priests of Isis and Osiris.

**SISYMBRIUM**, water-cress, in botany, a genus of plants, whose flower is tetrapetalous and cruciform; the petals are oblong, and spreading with small unguis: the fruit is a long incurved bilocular pod, opening with two valves, and filled with small seeds.

This genus includes the radicle of Dillenius. See the article RADICULA.

The common water-cress grows in marshes, brooks, rivers, ditches full of water, and other moist places in many parts of England.

The young leaves of this plant are frequently eaten in the spring as a salad, and are preferred by many to all other sorts of salads for their agreeable, warm, bitter taste: it is aperient, cleansing, and good against the gravel and dropsy; and is recommended as a specific against the scurvy, for which intention it is eaten in large quantities with great success: it is good against obstructions of the viscera, and consequently in jaundices, and many of the chronic diseases: it is also a powerful diuretic, and promoter of the menses. The best way of using it is in manner of a salad, or by drinking the expressed juice, which is at present much a custom with us in spring, with that of brook-lime, &c.

**SISYRINCHIUM**, in botany, a genus of plants, the flower of which consists of six oblong patent petals, which have an acute point: the stamina are three very short filaments, terminated with bifid antheræ, fixed to the base of the style: the fruit is an oval three-cornered capsule, having three cells, containing a number of roundish seeds.

**SISYRINCHIUM**, is also the name whereby some authors call the plant iris. See the article IRIS.

**SITE**, or **SCITE**, *Situs*, denotes the situation of a house, messuage, &c. and sometimes the ground-plot, or spot of earth it stands on.

**SITUS**, in logic, is one of the predicaments declaring a subject to be so and so placed: and in geometry and algebra, it denotes the situations of lines, surfaces, &c.

**SIUM**, water-parsnep, in botany, a genus of umbelliferous plants, whose general corolla is uniform, each proper one consists of five inflexed heart-shaped petals, which are equal, and five stamina: the fruit is furrowed, of an oval or roundish form, and divisible into two seeds, which are convex and striated on one side, and plane on the other.

This genus includes the sisarum of Tournefort. See the article SKIRRET.

**SIXTH**, *Sexta*, in music, one of the simple original concords, or harmonical intervals.

**SIZE**, the name of an instrument used to find the bigness of fine round pearls withal.

SIZE,

**SIZE**, is also a sort of paint, varnish, or glue, used by painters, &c.

The shreds and parings of leather, parchment, or vellum, being boiled in water and strained, make size.

**SKAITE**, in ichthyology, the variegated raia, with the middle of the back smooth, and one row of spines on the tail.

**SKELETON**, *σκελετον*, in anatomy, an assemblage or arrangement of all the bones of a dead animal, dried, cleansed, and disposed in their natural situation, and kept in that order by means of wires, &c.

**SKIFF**, or **SQUIFF**, the least of two ship-boats, serving chiefly to go ashore in, when the ship is in harbour.

**SKIN**, *Cutis*, in anatomy. See the articles **CUTIS** and **CUTICULA**.

**SKIRMISH**, in war, a disorderly kind of combat, or encounter, in presence of two armies, between small parties, or persons, who advance from the body for that purpose, and introduce to a general and regular fight.

**SKIRRET**, *Sisarum*, in botany, is accounted a species of sum. See the article **SUM**.

The root of this plant is thought to be very wholesome and nourishing; and the leaves eaten either crude or boiled, are said to break and expel the stone in the kidneys and bladder, and to excite urine.

**SKULL**, *Cranium & Calvaria*, in anatomy, that part of the head which forms its great bony cavity; and in a living subject contains the brain. See the articles **HEAD** and **BRAIN**.

**SKY**, the blue expanse of air and atmosphere. The azure colour of the sky Sir Isaac Newton attributes to vapours, beginning to condense there, and which have got consistence enough to reflect the most reflexible rays. M. De la Hire attributes it to our viewing a black object, viz. the dark space beyond the regions of the atmosphere, through a white or lucid one, viz. the air illuminated by the sun; a mixture of black and white always appearing blue. See the article **COLOUR**.

**SLAB**, an outside sappy plank or board sawed off from the sides of a timber-tree: the word is also used for a flat piece of marble.

**SLATE**, *Stegania*, in the history of fossils, a stone of a compact texture and laminated structure, splitting into fine plates.

**SLAVE**, a person in the absolute power of a master, either by war or conquest.

Slavery is absolutely abolished in Britain and France, as to personal servitude. Slaves make a considerable article of the traffic in America.

**SLEDGE**, a kind of carriage without wheels, for the conveyance of very weighty things, as huge stones, &c.

This is also the name of a large smith's hammer, to be used with both hands. Of this there are two sorts; the uphand-sledge, which is used by under-workmen, when the work is not of the larger sort; it is used with both the hands before, and they seldom raise it higher than their head; but the other, which is called the about-sledge, and which is used for battering or drawing out the largest work, is held by the handle with both hands, and swung round over their heads at their arm's ends, to strike as hard a blow as they can.

**SLEEP** is defined to be that state wherein the body appearing perfectly at rest, external objects move the organs of sense as usual, without exciting the usual sensations.

With regard to medicine, sleep is defined by Boerhaave, to be that state of the medulla of the brain, wherein the nerves do not receive so copious nor so forcible an influx of spirits upon the brain, as is required to enable the organs of sense and voluntary motion, to perform their functions. Sleep being one of the non-naturals, it is not possible for those to preserve their health, who do not go to sleep in a regular manner; for sleep repairs the spirits, which are dissipated by watching; and consequently it restores the strength of those who are weak, indisposed, or labour much. It likewise promotes perspiration, contributes greatly to digestion, and more to nutrition.

For the sleepy diseases, see the articles **CARUS**, **COMA-VIGIL**, **COMA-SOMNOLENTUM**, **LETHARGY**, &c.

**SLEEPER**, or the **GREAT SLEEPER**, in zoology, the hairy-tailed mus with red feet.

This is the size of the rat, but more corpulent; the head is short and thick; the opening of the mouth small; the nostrils flesh-coloured; the eyes large, black, and prominent; and the ears large and naked. This is frequent in many parts of Europe, and retires in winter into caverns under the ground, where it carries a considerable store of nuts and other fruits.

**SLEEPERS**, in natural history, a name given to some animals, which are said to sleep all the winter; such as bears, marmotes, dormice, bats, hedgehogs, swallows, &c. We are told, in Med. Essays of Edinb. that these do not feed in winter, have no sensible evacuations, breathe little or none at all, and that most of the viscera cease from their functions. Some of these creatures seem to be dead, and others to return to a state like that of a foetus before the birth; in this condition they continue, till by length of time maturing the process, or by new heat, the fluids are attenuated, the solids stimulated, and the functions begin where they left off.

**SLEEPERS**, in the glass-trade, are the large iron-bars crossing the smaller ones, and hindering the passage of the coals, but leaving room for the ashes.

N n SLEEPERS,

**SLEEPERS**, in a ship, timbers lying before and aft, in the bottom of the ship, as the rung-heads do: the lowermost of them is bolted to the rung-heads, and the uppermost to the futtocks and rungs.

**SLIDING**, in mechanics, is when the same point of a body, moving along a surface, describes a line on that surface.

**SLING**, *Funda*, an instrument serving for casting stones with great violence.

**SLINGING** is used variously at sea, but chiefly for the hoisting up casks, or other heavy things, with slings, i. e. contrivances of ropes spliced into themselves, at either end, with one eye big enough to receive the cask, or other thing, to be slung.

**SLIPS**, among gardeners, are small twigs torn off the branches of divers plants, and by which they are propagated more easily than by cuttings.

**SLITTING-MILL**. See **SMITHERY**, and *E-merson's MECHANICS*.

**SLOANEA**, or **SLOANA**, in botany, a genus of plants, whose flower is destitute of a corolla; the calyx is monophyllous, and divided into seven lanceolated segments; the filaments are subulated and numerous, with the antheræ joined to their sides: the fruit is a large roundish echinated capsule, having four cells, which contain oval, obtuse, fleshy seeds, which inclose each an oblong nucleus.

**SLOATS of a Cart**, the under-pieces which keep the bottom of the cart together. See the article **CART**.

**SLOE-TREE**, in botany, a species of the prunus or plum. See the article **PLUM**.

**SLOOP**, a sort of floating vessel, otherwise called shallop. In our navy, sloops are tenders on the men of war, and are usually of about sixty tons, and carry about thirty men.

**SLUICE**, in hydraulics, a frame of timber, stone, earth, &c. serving to retain and raise the water of the sea, a river, &c. and on occasion to let it pass: such is the sluice of a mill, which stops and collects the water of a rivulet, &c. in order to discharge it at length, in greater plenty, upon the mill wheel: such also are those used in drains, to discharge water off lands; and such are the sluices of Flanders, &c. which serve to prevent the waters of the sea overflowing the lower lands, except when there is occasion to drown them.

Sometimes there is a canal between two gates or sluices, in artificial navigation, to save the water, and render the passage of boats equally easy and safe, upwards and downwards; as in the sluices of Briare, in France, which are a kind of massive walls, built parallel to each other at the distance of twenty or twenty-four feet, closed with strong gates at each end, between which is a kind of canal or chamber, considerably longer than broad, wherein a vessel being inclosed, the water is let out at the first gate, by which the vessel is raised fifteen or sixteen feet, and passed out of this canal into an-

other much higher. By such means a boat is conveyed out of the Loire into the Seyne, though the ground between them rise above one hundred and fifty feet higher than either of those rivers.

**SMACK**, a small vessel with but one mast. Sometimes they are employed as tenders on a man of war, and are used for fishing upon the coasts, &c.

**SMALLAGE**, in botany, a species of apium or parsley. See the article **PARSLEY**.

Smallage is aperient and discussive; its root is one of the five great openers, and the seeds are reckoned among the four lesser hot seeds; it is very good in gross constitutions and infarctions of the lungs, especially if eat with oil and mustard. There needs no trouble to reduce it into any medicinal form, since it may be eaten as conveniently and agreeably in fallads.

**SMALT**, a preparation of arsenic, made as follows: the remaining matter of the cobalt from which the flowers have been sublimed being suffered to cool, and then taken out of the furnace, is reduced to fine powder, and calcined over again in the same furnace, and this repeated till there is not the least particle of flame or smoke seen to arise from any part of it. The cobalt thus freed from its arsenical and sulphureous part, is then ground to an impalpable powder, and a mixture is made of one hundred pounds of this powder, fifty pounds of pure white pot-ash, and a hundred and fifty pounds of pure white sand; this is all ground together upon a mill, and then put into a proper furnace, like those of our glass-houses, where it runs into an elegant deep blue glass. This is afterwards ground to powder in mills for that purpose, and makes what we call smalt or powder-blue, used by our painters and washerwomen. It has no use in medicine. See the article **COBALT**.

**SMARAGDUS**, the **EMERALD**, in natural history. See the article **EMERALD**.

**SMECTIS**, a name by which some call fuller's earth. See the article **FULLER**.

**SMELL**, *Odor*, with regard to the organ, is an impression made on the nose, by little particles continually exhaling from odorous bodies: with regard to the object, it is the figure and disposition of odorous effluvia, which, sticking on the organ, excite the sense of smelling: and with regard to the soul, it is the perception of the impression of the object on the organ, or the affection in the soul resulting therefrom.

The principal organs of smelling are the nostrils, and the olfactory nerves; the minute ramifications of which latter are described throughout the whole concave of the former.

According to Boerhaave, the act of smelling is performed by means of odorous effluvia floating in the air; being drawn into the nostrils, in inspiration, and struck with such force against the fibrillæ of the olfactory nerves, which the figure of the  
nose,

nose, and the situation of the little bones, tender opposite thereto, as to shake them, and give them a vibratory motion; which action, being communicated thence to the common sensory, occasions an idea of a sweet, or foetid, or sour, or an aromatic, or a putrified object, &c. The matter in animals, vegetables, fossils, &c. which chiefly affects the sense of smelling, Boerhaave observes, is that subtle substance inherent in the oily parts thereof, called spirit; for that, when this is taken away from the most fragrant bodies, what remains has scarce any smell at all; but this, poured on the most inodorous bodies, gives them a fragrantcy.

Willis observes, that brutes have, generally, the sense of smelling in much greater perfection than man; and by this alone, they distinguish the virtues and qualities of bodies unknown before; hunt out their food at a great distance, as hounds, and birds of prey; or hid among other matters, as ducks, &c. Man having other means of judging of his food, &c. did not need so much sagacity in his nose; yet have we instances of a great deal, even in man. In the *Histoire des Antilles*, we are assured, there are negroes who, by the smelling alone, can distinguish between the footsteps of a Frenchman and a negro.

The chemists teach, that sulphur is the principle of all smells, and that those are more or less strong, as the sulphur in the odorous body is more or less dried or exalted. Sulphur, they say, is the foundation of odours, as salt is of flavours, and mercury of colours. See the article **SULPHUR**, &c.

Smell, like taste, consists altogether in the arrangement, composition, and figure of the parts, as appears from the following experiments of Mr. Boyle. 1. From a mixture of two bodies, each whereof is of itself void of smell, a very urinous smell may be drawn, that is, by grinding of quick lime with sal-ammoniac. 2. By the admixture of common water, which, of itself, is void of all smell, or inodorous, another inodorous body may be made to emit a very rank smell. Thus camphor, dissolved in oil of vitriol, is inodorous, yet, mixed with water, immediately exhales a very strong smell. 3. Compound bodies may emit smells which have no similitude to the smell of the simples they consist of. Thus oil of turpentine, mixed with a double quantity of oil of vitriol, and distilled; after distillation, there is no smell but of sulphur, and what is left behind, the retort being again urged by a more violent fire, yields a smell like oil of wax. 4. Several smells are only to be drawn forth by motion and agitation. Thus glass, stones, &c. which even when heated yield no smell, yet, when rubbed and agitated in a peculiar manner, emit a strong smell; particularly beech-wood, in turning, yields a kind of rosy smell. 5. A body that has a strong smell, by being mixed with an inodorous one, may cease to have any smell at all. Thus if aqua-fortis, not

well dephlegmated, be poured on salt of tartar, till it ceases to ferment, the liquor, when evaporated, will yield inodorous crystals, much resembling salt of nitre; yet when burnt, will yield a most noisome smell. 6. From a mixture of two bodies, one whereof smells extremely ill, and the other not well, a very pleasant aromatic odour may be gained, viz. by a mixture of aqua-fortis, or spirit of nitre, with an inflammable spirit wine. 7. Spirits of wine, by mixing with an almost inodorous body, may gain a very pleasant aromatic smell. Thus inflammable spirits of wine, and oil of Dantzic vitriol, mixed in equal portions, then digested, and at last distilled, yield a spirit of a very fragrant smell. 8. A most fragrant body may degenerate into a foetid one, without the admixture of any other body. Thus, if the spirit mentioned in the former experiment be kept in a well-closed receiver, it will soon turn to the rankness of garlic. 9. From two bodies, one whereof is inodorous and the other foetid, a very pleasant smell may arise, much resembling musk, &c. by putting pearls into spirit of vitriol; for, when dissolved, they yield a very agreeable smell.

**SMELT**, in ichthyology, the osmerus, with seventeen rays in the pinna ani. This is a beautiful little fish; its length is five or six inches, and its breadth not great in proportion, but the thickness is considerable: the head is of an oblong figure, and somewhat acute; the opening of the mouth is large, the back is convex, and the belly somewhat flat; the lower jaw is a little longer than the upper; the nostrils stand in the middle between the eyes and the extremity of the rostrum; they have each two apertures; the eyes are large and round, the pupil is black, and the iris of a silvery white, but tinged a little with blue towards the upper part.

**SMELTING**, in metallurgy, the fusion or melting of the ores of metals, in order to separate the metalline part from the earthy, stony, and other parts. See the articles **FUSION**, **ORE**, **FLUX**, **GOLD**, **SILVER**, &c.

**SMILAX**, rough bind-weed, in botany, a genus of plants, whose flowers are apetalous; they are male and female, growing on different plants; the cups are campanulated, and divided each into six spreading oblong segments, reflexed at the top, and joining at their base; the stamina of the male flower are six filaments, topped with oblong antheræ: the fruit is a globose, bilocular berry, containing two round seeds.

**SMIRIS**, in natural history, the same with emery. See the article **EMERY**.

**SMITHERY**, or **SMITHING**, a manual art, by which an irregular lump of iron is wrought into an intended shape. See the article **FORGE**.

**SMOKE**, or **SMOAK**, *Fumus*, a humid matter, exhaled in the form of vapour, by the action of fire and heat. See the articles **FIRE**, **HEAT**, and **EXHALATION**.

SMOKE-

**SMOKE-SILVER**, and **SMOKE-PENNY**, a payment made to the ministers of several parishes in lieu of tithe-wood.

**SMUGGLERS**, in law, those persons who conceal and run prohibited goods, or goods that have not paid his majesty's customs.

**SMUT**, in husbandry, a disease in corn; when the grains, instead of being filled with flour, are full of a stinking black powder.

As to the cause of this distemperature, some have attributed it to excessive rankness, or fatness of the soil; to the manuring the land with rotten vegetables; and to the sowing smutty seed. Mr. Bradley thinks it is owing to the same cause with a blight, viz. to multitudes of insects. But Mr. Tull is convinced, from experiment, that it is caused by too much moisture; for planting several plants of corn in troughs of very moist earth, they all produced smutty ears, while very few such were found in the field, from whence these plants were taken.

There are two remedies for the smut, recommended by writers on husbandry, viz. steeping the seed in salt brine, and changing the seed. See the articles **SEED** and **CHANGE**.

As to the steeping of seed, when wheat is intended for drilling, it must be soaked in a brine of pure salt, dissolved in water, since urine is found to be highly prejudicial. The most expeditious way of brining wheat for drilling, is to lay it in a heap, and wash it with a strong brine sprinkled on it, stirring it up with a shovel, that it may be all equally brined, or wetted with it: after this, sift on some fine lime all over the surface, and stir it up, still sifting on more in the same manner till the whole is dusted with the lime; it will then soon be dry enough to be drilled without farther trouble. It must be quick-lime in its full strength, that is used on this occasion.

The bread made of smutty corn is very pernicious, acting as a narcotic, and occasioning not only sleepiness, but vertigoes, and even convulsions.

**SMYRNIUM**, *Alexanders*, or *Alesanders*, in botany. See the article **ALESANDERS**.

**SNAFFLE**, in the manege, is a very slender bit-mouth, without any branches, much used in England; the true bridles being reserved for the service of war.

The snaffle, or small watering-bit, is commonly a scratch-mouth, with two very little straight branches, and a curb, mounted with a head-stall, and two long reins.

**SNAIL**, *Limax*, in zoology, a genus of the gymnarthria, or naked insects; the body of which is of a figure approaching to cylindric, and is perforated at the side; the tentacula, or horns, as they are called, are four in number, and two of them have the appearance of eyes.

Snails are all hermaphrodites, and esteemed provocatives by the Asiatics.

**SNAKE**, *Anguis*, in zoology. See the article **ANGUIS**.

The common snake is a harmless and inoffensive animal, and might even be kept tame in houses to destroy vermin: its flesh is restorative, like that of the viper. See the article **VIPER**.

For the blood-snake, rattle-snake, &c. see **HÆMORRUS**, **RATTLE-SNAKE**, &c.

**SNAKE-ROOT**, *Serpentaria*, in botany. See the article **SERPENTARIA**.

**Rattle-SNAKE-ROOT**, *Polygala*, in botany. See the article **POLYGALA**.

**SNAKE-STONE**, a name given to the ammonitæ. See **AMMONITÆ**.

**SNAKE-WEED**, *Polygonum*, in botany. See **POLYGONUM**.

**SNAP-DRAGON**, *Antirrhinum*, in botany. See **ANTIRRHINUM**.

**SNATCH-BLOCK**, among seamen, a kind of pulley. See **PULLEY**.

**SNEEZING**, *Sternutatio*, a convulsive motion of the muscles of the breast, whereby the air is expelled from the nose, with much vehemence and noise.

Sneezing is caused by the irritation of the upper membrane of the nose, occasioned by acrid substances floating in the air, or by medicines called sternutatories.

**SNEEZWORT**, *Ptarmica*, in botany. See **PTARMICA**.

**SNIPE**, in ornithology, a species of numenius, with four brown streaks on the back; it is a small but beautiful bird, and its flesh is delicate, and much esteemed at table.

**SNOW**, *Nix*, in meteorology, a meteor produced in this manner: when the vapours are become considerably condensed, yet not so far as to be liquified, or dissolved into water; then by a special degree of coldness in the upper region of the air, the particles of the condensed vapour are changed into ice; several of which adhering together, form little fleeces of a white substance, somewhat heavier than the air; and therefore descend in a slow and gentle manner through it; being subject, by reason of its lightness, to be driven about by the various motions of the air and wind; and is what, when arrived to the surface of the earth, we call snow. See **FROST**, **HAIL**, &c.

The uses of snow must be very great, if all be true Bartholin has said in its behalf, in an express treatise, *De Nivis Ufa Medico*; he there shews, that it fructifies the earth (which, indeed, is a very old and general opinion) preserves from the plague; cures fevers; cholics, tooth-achs, sore eyes; and pleurifies; for which last use, his countrymen of Denmark use to keep snow-water gathered in March. He adds, that it contributes to the prolongation of life; giving instances of people in the Alpine mountains that live to great ages; and to the

the preserving dead bodies, instances whereof he gives of persons buried under the snow in passing the Alps, which are found uncorrupted in the summer, when the snow is melted.

He observes, that, in Norway, snow-water is not only their sole drink in the winter, but snow even serves for food; people having been known to live several days, without any other sustenance.

Indeed, the generality of these medicinal effects of snow, are not to be ascribed to any specific virtue in snow, but to other causes. It fructifies the ground, for instance, by guarding the corn or other vegetables, from the intenser cold of the air, especially the cold piercing winds. And it preserves dead bodies, by constipating and binding up the parts, and thus preventing all such fermentations or internal conflicts of their particles, as would produce putrefaction.

Snow may be preserved by ramming it down in a dry place, under-ground, and covering it with chaff, in the manner of ice. See ICE.

**SNOWDROP**, *Galanthus*, in botany. See GALANTHUS.

**SNOWDROP-TREE**, the same with the chionanthus. See CHIONANTHUS.

**SNUFF**, a powder chiefly made of tobacco, the use of which is too well known to need any description here. See TOBACCO.

However, though tobacco be the basis of snuff, yet a multiplicity of other matters are often added, to give it an agreeable scent.

**SOAL-FISH**, *Solea*, in ichthyology, the English name of the long-bodied pleuronectes, with rough scales on both sides. See PLEURONECTES.

**SOAP**, or **SOPE**, in commerce, and the manufactures, a kind of paste, sometimes hard and dry, and sometimes soft and liquid, much used in washing, whitening linens, and by dyers, fullers, &c.

The principal soaps of our manufacture, are the soft, the hard, and the ball soap; all which consist of an intimate union of the salt of pot-ash, with oil, or animal fat.

1. The soft-soap is either green or white. The principal ingredients in the green kind are leys drawn from pot-ashes, and lime boiled up with tallow and oil.

First, the ley and tallow are put into the copper together, and, when melted, the oil is put to them, and the copper made to boil; then they damp or stop up the fire, while the ingredients remain in the copper to knit or incorporate; which being done, they set the copper boiling again, feeding or filling it with leys as it boils, till they have put in a sufficient quantity; after which they boil it off with all convenient speed, and put it into barrels.

One sort of white-soap is made after the same manner with green-soap, excepting that they do not use any oil in this. Another sort of white soft-

soap is made from leys of ashes of lime, boiled up twice with tallow.

First, they put a quantity of leys and tallow into the copper together, which is kept boiling, being fed with leys as it boils, till it is boiled enough, or that they find it grains; then they separate or discharge the leys from the tallowish part, which they put into a tub, throwing away the ley: this they call the first half-boil. Then they charge the copper again with fresh tallow and ley, and put the first half-boil out of the tub into the copper a second time, and keep it boiling with fresh ley and tallow, till it is brought to perfection, and afterwards filled out into soap-casks.

2. Hard-soap is made of ashes and tallow, and commonly boiled at twice; the first boiling they also call a half-boiling, which is performed exactly after the same manner as the first half-boil of the soft white-soap. Then they charge the copper again with fresh ley, and put into it the first half-boil again, feeding it with ley as it boils, till it is boiled enough, or till it grains; then they discharge the ley from it, and put the soap into a frame to boil and harden.

3. Ball-soap is made also of ley from ashes and tallow; they put the ley into the copper, and boil it till the watery part is quite gone, and there is nothing left in the copper but a sort of nitrous matter (which is the very strength and essence of the ley) then they put tallow to it, and keep the copper boiling and stirring for half an hour or more, in which time the soap is completed, which they put into tubs or baskets with sheets in them, and immediately (while soft) make it into balls.

It takes up near twenty-four hours to boil away the watery part of the ley.

The process of soap-boiling, as at present practised, being a very tedious, as well as expensive, operation, Dr. Shaw proposes a method to shorten it, by substituting motion in the place of fire: this motion might be easily given, by an engine, to any quantities of the ingredients at a time; and that such a method is effectual for making soap, the doctor proved by the following experiment: he mixed, in a large phial, half a pint of soap-ley, with an ounce, or more, of oil-olive; and shaking these together for a quarter of an hour, a true cake of soap was obtained on the top of the liquor, which hardened on being exposed to the air.

**SOAP-EARTH**, or **SOAP-ROCK**, in natural history. See STEATITES.

**SOAP-WORT**, *Sapenaria*, in botany. See SAPONARIA.

**SOC**, or **SOK**, *Soca*, in law-books, denotes jurisdiction. See JURISDICTION.

**SOCAGE**, an ancient tenure, by which lands were held on condition of ploughing the lord's lands, and doing the operations of husbandry,

at their own charges. See the articles **TENURE** and **HUSBANDRY**.

**SOCUS**, in antiquity; a kind of high shoe, reaching above the ankle, worn by comedians, as the cothurnus was by tragedians. See **COTHURNUS**, **COMEDY**, **TRAGEDY**, and **DRAMA**.

**SOCIETY**, *Societas*, in general, denotes a number of persons united together for their mutual assistance, security, interest, or entertainment.

**Royal SOCIETY**, an academy, or college, established by charter, by king Charles II. for promoting natural knowledge, and useful arts, by experiments. See the article **ACADEMY**.

It consists of several hundred fellows, or members, mostly British; some persons of the highest rank, and many eminent gentlemen and learned men of other nations.

Their meetings are held once a week, at their house in Crane-Court, Fleet-Street, London; where they discourse upon the productions and rarities of nature and art, and consider how the same may be improved for the good of mankind: here are also read letters, and other philosophical papers, sent by ingenious persons, both at home and abroad; upon which they discourse in the plainest manner, without affecting studied speeches.

This society, of which his Britannic majesty is perpetual patron, is governed by a council of twenty-one members, ten of whom are yearly chosen out of the society, on St. Andrew's day: the chief of the council bears the title of President, whose proper office is to call and dissolve the meetings, to propose the matter to be debated, call for experiments, and admit such members as shall be elected, which must be by a majority of at least twenty-one votes; whereupon he is admitted, after paying 40s. and subscribing, that he will endeavour to promote the good of the Royal Society of London, by the improvement of natural knowledge; and being thus admitted, he afterwards pays 13s. a quarter, as long as he continues a member of the society.

**SOCINIANS**, in church history, a sect of Christian heretics, so called from their founder Faustus Socinus, a native of Sienna, in Italy.

He, about the year 1574, began openly to declare against the Catholic faith, and taught, 1. That the Eternal Father was the one only God; that the Word was no more than an expression of the Godhead, and had not existed from all eternity; and that Jesus Christ was God no otherwise than by his superiority over all creatures who were put in subjection to him by the Father.

2. That Jesus Christ was not a mediator between God and men, but sent into the world to serve as a pattern of their conduct; and that he ascended up to heaven only as it were to take a journey thither.

3. That the punishment of hell will last but for a certain time, after which the body and soul will be destroyed.

And, 4. That it is not lawful for princes to make war.

These four tenets were what Socinus defended with the greatest zeal. In other matters, he was a Lutheran or a Calvinist; and the truth is, that he did but refine upon the errors of all the Antitrinitarians that went before him.

The Socinians spread extremely in Poland, Lithuania, and Transylvania. Their sentiments are explained at large in their catechism, printed several times under the title of *Catechesis Ecclesiarum Polonicarum, unum Deum Patrem, illiusque Filium unigenitum, una cum Sancto Spiritu, ex sacra scriptura confitentium*. They were exterminated out of Poland in 1655, since which time they have been chiefly sheltered in Holland, where, though their public meetings have been prohibited, they find means to conceal themselves under the names of Arminians and Anabaptists. See the article **ARMINIAN**.

**SOCLE**, or **ZOCLE**, in architecture, a flat square member under the bases of pedestals of statues, vases, &c. which serves as a foot or stand.

Continued socle, is a kind of continued stand or pedestal without either base or cornice, ranging round the whole building, called by Vitruvius, *stereobata*. See the article **STEREOBATA**.

**SOCMEN**, or **SOKEMEN**, such tenants as held their lands and tenements in socage; but the tenants in ancient demesne, seem most properly to be called socmans. See the article **SOCAGE**.

**SOCNA**, in our old writers, denotes some privilege, liberty, or franchise.

**SOCOME**, is taken for a custom of grinding corn at the lord's mill; whence came the name or term of bond socome, by which the tenants were bound to it; and also love socome, where they did it voluntarily out of love to their lord.

**SOCRATIC PHILOSOPHY**, the doctrines and opinions, with regard to morality and religion, maintained and taught by Socrates.

By the character of Socrates, left us by the ancients, particularly by his scholars Plato, Laertius, &c. he appears to have been one of the best and the wisest persons in all the heathen world. To him is ascribed the first introducing of moral philosophy, which is what is meant by that usual saying, that "Socrates first called philosophy down from heaven to earth;" that is, from the contemplation of the heavens and heavenly bodies, he led men to consider themselves, their own passions, opinions, faculties, duties, actions, &c. He wrote nothing himself, yet all the Grecian sects of philosophers refer their origin to his discipline, particularly the Platonists, peripatetics, academics, cyrenaics, stoics, &c. but the greatest part of his philosophy we have in the works of Plato. See the article **PLATONISM**.

**SODOMY**, the unnatural crime of buggery, thus called from the city of Sodom, which was destroyed

stroyed by fire for the same. The Levitical law adjudged those guilty of this execrable crime to death, and the civil law assigns the same punishment to it. Our law also makes it felony.

There is no statute in Scotland against sodomy; the libel of this crime is therefore founded on the divine law, and practice makes its punishment to be burning alive.

SOFA, in the Turkish customs, a bench of wood, raised from the ground about a foot high, and placed round a hall or chamber for the people to sit down upon, or to lie along, and in that posture to take a view of what passes in the streets, &c. for these benches are surrounded with windows; they are covered with fine Turkey carpets; and upon that are placed cushions of sattin flowered with gold, or some other rich stuff.

SOFFITA, or SOFFIT, in architecture, any plafond or ceiling formed of cross beams of flying corniches, the square compartments or pannels of which are enriched with sculpture, painting, or gilding; such are those in the palaces of Italy, and in the apartments of Luxembourg at Paris. This word is particularly used for the under side or face of an architrave, and for that of the corona or larmier, which the ancients called lacunar, the French plafond, and we usually the drip. It is enriched with compartments of roses, and has eighteen drops in the Doric order disposed in three ranks, six in each, placed to the right-hand of the guttæ, and at the bottom of the triglyphs.

SOFTENING, in painting, the mixing and diluting of colours with the brush or pencil. To soften designs in black and white made with the pen, &c. signifies to weaken the tint. To soften a portrait, according to Felibien, is to change some of the strokes, and give a greater degree of sweetness and softness to the air thereof, which before had something rough and harsh in it.

SOGETTO, subject, in music, is used for a song or melody, above or below which some counterpoint is to be made: a counterpoint above the subject, is when the lower part is the subject; in this sense it is called *canto fermo*. When the counterpoint is made below the subject, the upper part is made the subject. If this subject does not change the figure or situation of notes, be it above or below the counterpoint, it is called the invariable subject; and if it changes, the variable subject. *Sogetto* is also used for the words to which some compositions are to be adapted. And lastly, this word is made use of for a succession of many notes of one, two, or more measures, disposed in such a manner as to form one or more fugues. See COUNTERPOINT, &c.

SOIL, *Solum*, in agriculture and gardening, denotes earth or ground, considered with regard to the quality of its mould for the production and growth of vegetables. See the article EARTH.

The land of England, as considered by the farmer, is reduced into nine sorts of soil: the sandy, the gravelly, the chalky, the stony, the rocky, the hazely, the black earth, the marsh, and the clay-land. See the articles SAND, GRAVEL, &c.

SOIT FAIT COMME IL EST DESIRE', *Be it done as it is desired*, a form used when the king gives the royal assent to a private bill preferred in parliament.

SOL, in music, the fifth note of the gamut, *ut, re, mi, fa, sol, la*. See GAMUT.

SOLÆUS, or SOLARIS, in anatomy, one of the extensor muscles of the foot, rising from the upper and hinder part of the tibia and fibula. This is a large and fat muscle, thicker at the middle than at the edges, and is nearly of an oval figure.

SOLANDRA, in botany, a genus of plants, producing male and female flowers, which grow in an umbel; the male flower has five equal petals, and the female six of the same form: the fruit is an oblong capsule, containing a single seed.

SOLANUM, nightshade, in botany, a genus of plants, whose flower is monopetalous and rotated, the corolla of which is very short, and the limb is divided half through into five large plicated pointed segments, it contains five small subulated filaments, topped with oblong connivent antheræ; the fruit is a round smooth berry, punctated at the top, containing two cells, which are filled with roundish compressed seeds, and placed on a convex fleshy receptacle.

This genus includes the melongena and lycopersicon of Tournefort.

The common nightshade rises a firm angular stalk, to the height of a foot and a half, of a blackish-green colour, and divided into several branches; the leaves are oblong, acute-pointed, smooth, of a dark colour, and full of a greenish juice; it grows wild in gardens, dunghills, on the side of highways, &c. and flowers in September. This plant is used to allay inflammations, to soften and relax the fibres which undergo too violent a tension: the bruised herb is applied to the piles, or the part bathed with the juice a little warmed; internally it is seldom used, being often attended with dangerous consequences.

SOLAR, something belonging to the sun: thus the solar system is that system of the world wherein the heavenly bodies are made to revolve round the sun as the center of their motion. See COPENNICAN.

Also the solar year is that consisting of three hundred and sixty-five days, five hours, and forty-nine minutes, in opposition to the lunar year, consisting of three hundred and fifty-four days.

SOLDANELLA, in botany, a plant whose root is fibrous and perennial, the leaves are almost kidney-shaped, of a dark green colour, and stand on long foot-stalks: the flowers come out in pairs placed on a footstalk; they are monopetalous and

campanulated, with their edges cut into acute segments, and of a blue or white colour: the flower is succeeded by an oblong taper capsule obliquely striated, containing one cell, and opening at the top with ten indentures; the seeds are numerous, small, and acuminate, with a columnar receptacle.

This plant is a native of the Alps, and the mountains in Germany, and is propagated here by parting the roots in September.

**SOLDER, SODDER, or SODER**, a metallic or mineral composition used in soldering or joining together other metals. See the next article.

Solders are made of gold, silver, copper, tin, bismuth, and lead; usually observing, that in the composition there be some of the metal that is to be soldered mixed with some higher and finer metals. Goldsmiths usually make four kinds of solder, viz. solder of eight, where to seven parts of silver there is one of brass or copper; solder of six, where only a sixth part is copper; solder of four, and solder of three. It is the mixture of copper in the solder that makes raised plate come always cheaper than flat. The solder used by plumbers is made of two pounds of lead to one of block-tin. Its goodness is tried by melting it and pouring the bigness of a crown-piece upon a table; for if good, there will arise little bright shining stars therein. The solder for copper is made like that of the plumbers, only with copper and tin; for very nice works, instead of tin they sometimes use a quantity of silver. Solder for tin is made of two thirds of tin and one of lead; but where the work is any thing delicate, as in organ-pipes, where the juncture is scarce discernable, it is made of one part of bismuth and three parts of pewter.

**SOLDERING**, among mechanics, the joining and fastening together two pieces of the same metal, or of two different metals, by the fusion and application of some metallic composition on the extremities of the metals to be joined. See the last article.

To solder upon silver, brass, or iron: take silver, five penny-weight; brass, four penny-weight; melt them together for soft-solder, which runs soonest. Take silver five penny-weight; copper, three penny-weight; melt them together for hard solder. Beat the solder thin, and lay it on the place to be soldered, which must be first fitted and bound together with wire, as occasion requires; then take borax in powder, and temper it like pap, and lay it upon the solder, letting it dry; then cover it with quick coals, and blow, and it will run immediately; take it presently out of the fire, and it is done. It is to be observed, that if any thing is to be soldered in two places, which cannot well be done at one time, you must first solder with the harder solder, and then with the soft; for if it be first done with the soft, it will unfold again before the other is soldered. Let it be observed, that if you would not

have your solder run about the piece that is to be soldered, you must rub such places over with chalk.

In the soldering either of gold, silver, copper, and all the metals before-mentionee, there is generally used borax in powder, and sometimes rosin. As to iron, it is sufficient that it be heated red-hot, and the two extremities thus hammered together, by which means they will become incorporated into one another.

**SOLDIER**, a military man lifted to serve a prince or state, in consideration of a certain daily pay.

The soldiers are properly the land forces of a kingdom or state; but in England it is against the ancient law to keep an army of soldiers in time of peace. Where any soldier that is lawfully retained shall depart from his colours without licence, he is declared to be guilty of felony by 18 Hen. VI. c. 9. and every soldier who either causes a mutiny or deserts the service, shall be punished with death or otherwise, as a court-martial shall think fit. Also persons suspected of desertion, are to be apprehended by constables, who shall be allowed a reward of 20 s. for every such deserter.

By the 4 Geo. I. c. 4. it is ordained, that no soldier shall be taken out of the service by any process at law, unless it be for some criminal matter, or where the debt he owes amounts to 10 l. at the least, of which affidavit is to be made, &c. Soldiers must be quartered in inns and alehouses only, and not in private houses, without the consent of the owners, under certain penalties: and where victuallers refuse soldiers quartered on them, or constables receive any reward for excusing their neglect, they forfeit a sum not above 50 l. nor under 30 s. by 3 Geo. II. c. 2. A person enlisted for a soldier, within four days after, is to be carried before the next justice or chief magistrate of a town, and is to declare his assent that he lifted voluntarily, &c. but if he then dissents thereto, on his returning the money received, and paying 20 s. he may be discharged. In case any subject of Great-Britain or Ireland shall lift or enter himself, or procure any one to be enlisted a soldier to go beyond the seas, without leave obtained from his majesty, such person shall be punished as a felon by 8 and 9 Geo. II. There are acts annually made for punishing mutiny, &c. of soldiers and false musters, and for the better payment of the army and their quarters, &c. See **COURT-MARTIAL**.

**SOLE**, in the manege, a nail or sort of horn under a horse's foot, which is much more tender than the other horn that encompasses the foot, and by reason of its hardness is properly called the horn or the hoof. A horse's shoe ought to be so set upon the hoof as not to bear upon the sole, for otherwise the sole will be hurt, and not only make the horse lame, but corrupt the flesh that separates it from the

coffin-bone. To take out the sole, is to do it without touching the horn of the hoof; or if you take off the horn, you make a hoof-cast.

**SOLE-TENANT**, one that holds lands, &c. by his own right only, without any other person joined.

A person must be seized of a sole-estate to devise the same by will, or for the wife to have a dower therein, &c. And where a man and his wife hold land for their lives, the remainder to their son, in that case, if the man dies the lord shall not have heriot, because he does not die sole-tenant.

**SOLECISM**, *Soloeisismus*, in grammar, a false manner of speaking, contrary to the use of language and the rules of grammar, either in respect of declension, conjugation, or syntax.

**SOLEMN**, *Solemnis*, something performed with much pomp, ceremony, and expence: thus we say, solemn feasts, solemn funerals, solemn games, &c. See the articles **FEAST**, **FUNERAL**, &c.

Solemn, in law, signifies something authentic, or that is clothed in all its formalities.

**SOLFAING**, in music, the naming or pronouncing the several notes of a song, by the syllables *ut, re, mi, fa, sol*, &c. and in learning to sing it.

Of the seven notes in the French scale *ut, re, mi, fa, sol, la, si*, only four are used among us in singing, as *mi, fa, sol, la*: their office is principally in singing, that by applying them to every note of the scale, it may not only be pronounced with more ease, but chiefly that by them the tones and semitones of the natural scale may be better marked out and distinguished. This design is obtained by the four syllables *fa, sol, la, mi*. Thus from *fa* to *sol* is a tone, also from *sol* to *la*, and from *la* to *mi*, without distinguishing the greater or less tone; but from *la* to *fa*, also from *mi* to *fa*, is only a semitone. If then these be applied in this order, *fa, sol, la, fa, sol, la, mi, fa*, &c. they express the natural series from C; and if that be repeated to a second or third octave, we see by them how to express all the different orders of tones and semitones in the diatonic scale; and still above *mi* will stand *fa, sol, la*, and below it the same inverted *la, sol, fa*, and one *mi* is always distant from another an octave, which cannot be said of any of the rest, because after *mi* ascending come always *fa, sol, la, fa*, which are repeated invertedly descending.

To conceive the use of this, it is to be remembered, that the first thing in learning to sing, is to make one raise a scale of notes by tones and semitones to an octave, and descend again by the same; and then to raise and fall by greater intervals at a leap, as thirds and fourths, &c. and to do all this by beginning at notes of different pitch. Then those notes are represented by lines and spaces, to which these syllables are applied, and the learners

taught to name each line and space thereby, which makes what we call solfaing, the use whereof is, that while they are learning to tune the degrees and intervals of sound, expressed by notes on a line or space, or learning a song to which no words are applied, they may not only do it the better by means of articulate sounds, but chiefly, that by knowing the degrees and intervals expressed by those syllables, they may more readily know the places of the semitones, and the true distance of the notes. See the article **SINGING**.

**SOLICITOR**, or **SOLLICITOR**, *Solicitor*, a person employed to take care of, and manage suits depending in the courts of law and equity; and those of the lower sort, it is observed, are too often made use of, to the damage of the people, and the increase of champerty and maintenance. Solicitors are within the statute to be sworn and admitted by the judges, before they are allowed to practise in our courts, in like manner as attornies.

There is also a great officer of the law, next to the attorney-general, who is stiled the king's solicitor-general; who holds his office by patent, during the king's pleasure; has the care and concern of managing the king's affairs, and has fees for pleading, besides other fees arising by patents, &c. He hath his attendance on the privy-council; and the attorney-general and he were anciently reckoned among the officers of the exchequer; they have their audience, and come within the bar in all other courts.

**SOLID**, in philosophy, a body whose parts are so firmly connected together, as not to give way, or slip from each other, upon the smallest impression: in which sense, solid stands opposed to fluid.

Geometricians define a solid to be the third species of magnitude, or that which has three dimensions, viz. length, breadth, and thickness or depth.

A solid may be conceived to be formed by the revolution, or direct motion, of a superficies of any figure whatever, and is always terminated or contained under one or more planes or surfaces, as a surface is under one or more lines.

Solids are commonly divided into regular and irregular. The regular solids are those terminated by regular and equal planes, and are only five in number, viz. the tetrahedron, which consists of four equal triangles; the cube, or hexahedron, of six equal squares; the octahedron, of eight equal triangles; the dodecahedron, of twelve; and the icosihedron, of twenty equal triangles. See the articles **TETRAHEDRON**, **CUBE**, **OCTAHEDRON**, &c.

The irregular solids are almost infinite, comprehending all such as do not come under the definition of regular solids; as the sphere, cylinder, cone, parallelogram, prism, parallelopiped, &c. See the articles **SPHERE**, **CYLINDER**, &c.

**SOLID Angle**, is that formed by three or more planes meeting in a point, like the point of a diamond well cut.

**SOLID Bastion**. See **BASTION**.

**SOLID Numbers**, are those which arise from the multiplication of a plane number, by any other whatsoever; as 18 is a solid number made of 6 (which is plane) multiplied by 3; or of 9 multiplied by 2.

**SOLID Problem**, in mathematics, is one which cannot be geometrically solved, unless by the intersection of a circle and a conic section: or, by the intersection of two other conic sections, besides the circle.

As to describe an isosceles-triangle on a given right-line, whose angle at the base shall be triple to that at the vertex.

**Line of SOLIDS**, on the sector. See the article **SECTOR**.

**SOLIDS**, in anatomy, &c. denote the continent parts of the human body; being a congeries of pipes or vessels, which contain a liquor.

The solid parts of the body, though equally composed of vessels, are different with regard to their consistence; some being hard, and others soft. The hard, as the bones and cartilages, give firmness and attitude to the body, and sustain the other parts. The soft parts, either alone or together with the hard, serve to execute the animal functions.

**SOLIDAGO**, golden-rod, in botany, a genus of plants, whose flower is compound and radiated, consisting of hermaphrodite and female corollulæ; the hermaphrodite compose the disc, and are numerous and funnel-shaped; the female florets are ligulated, spear-shaped, and tridentated: the seeds are solitary, oblong, crowned with a hairy down, and contained in an oblong imbricated cup.

Golden-rod is common in gardens; the flowers are yellow, and produced in spikes in August and September; it is easily increased by parting the roots in October.

The leaves, which have a moderately astringent and bitter taste, are esteemed good in diarrhoeas and dysenteries, and have been much commended formerly as a restorative and vulnerary; and likewise for their diuretic and lithontriptic qualities.

**SOLIDITY**, *Soliditas*, that property of matter, or body, by which it excludes all other bodies from the place which itself possesses.

Among geometricians, the solidity of a body denotes the quantity or space contained in it, and is called also its solid content.

**SOLIDITY**, in architecture, is applied both to the consistence of the ground, whereon the foundation of a building is laid, and to a mass in masonry, of extraordinary thickness, without any cavity within.

**SOLILOQUY**, *Soliloquium*, a reasoning or discourse which a man holds with himself; or, more

properly, according to Papias, it is a discourse by way of answer to a question, that a man proposes to himself.

Soliloquies are become very common things on the modern stage; yet can nothing be more inartificial, or more unnatural, than an actor's making long speeches to himself, to convey his intentions to the audience. Where such discoveries are necessary to be made, the poet should rather take care to give the dramatic persons such confidants as may necessarily share their inmost thoughts, by which means they will be more naturally conveyed to the audience: yet is even this a shift, an accurate poet would not be found to have occasion for.

**SOLITARIES**, a denomination of nuns of St. Peter of Alcantara, instituted in 1676, the design of which is to imitate the severe penitent life of that saint; thus they are to keep a continual silence, never to open their mouths to any body but themselves; employ their time wholly in spiritual exercises, and leave the temporal concerns to a number of maids, who have a particular superior in a separate part of the monastery: they always go bare-footed, without sandals; gird themselves with a thick cord, and wear no linen.

**SOLO**, in music, a term used in pieces consisting of several parts, to mark those that are to perform alone.

**SOLOMON'S SEAL**, in botany, the English name of the polygonatum. See the article **POLYGONATUM**.

**SOLSTICE**, in astronomy, that time when the sun is in one of the solstitial points; that is, when he is at his greatest distance from the equator, thus called, because he then appears to stand still, and not to change his distance from the equator for some time; an appearance owing to the obliquity of our sphere, and which those living under the equator are strangers to.

The solstices are two in each year, the æstival or summer-solstice, and the hyemal or winter-solstice: the summer solstice is when the sun seems to describe the tropic of cancer, which is on June 22, when he makes the longest day: the winter-solstice is when the sun enters the first degree, or seems to describe the tropic of capricorn, which is on December 22, when he makes the shortest day. See the article **TROPIC**.

This is to be understood as in our northern hemisphere; for in the southern, the sun's entrance into capricorn makes the summer-solstice, and that into cancer the winter-solstice.

The two points of the ecliptic, wherein the sun's greatest ascent above the equator, and his descent below it, are terminated, are called the solstitial points; and a circle, supposed to pass through the poles of the world and these points, is called the solstitial colure.

The summer-solstitial point is in the beginning of the

the first degree of cancer, and is called the æstival or summer-point; and the winter solstitial point is in the beginning of the first degree of capricorn, and is called the winter-point. These two points are diametrically opposite to each other.

**SOLVENT**, the same with dissolvent. See the article **DISSOLVENT**.

**SOLUTION**, in chemistry, denotes an intimate mixture of solid bodies with fluids, so as seemingly to form one homogeneous liquor: the dissolving fluid is termed the dissolvent or menstruum.

As to the manner of effecting solutions, it varies according to the different solvents used for that purpose, and is reduced to the following heads by Boerhaave: 1. Solution is performed by water, by diluting, infusing, boiling, distilling, mixing, fermenting, putrefying, and separating. 2. With oil, by diluting, infusing, boiling, distilling, mixing, separating; but not by fermenting, or by putrefying. 3. With fire, by calcining, roasting, burning, melting, subliming, mixing, separating, and promoting several other operations. 4. With the assistance of air, by fermenting, putrefying, agitating, exciting, and adding other parts capable of dissolving. 5. With fermented spirits, by diluting, infusing, boiling, distilling, mixing, and making oils thinner. 6. With alkaline salts, by calcining, torrefying, burning, melting, mixing, and separating, according to the various force of a dry fire employed. 7. By volatile alkaline salts, by subliming in the dry way; and by diluting, distilling, and digesting in the moist way. 8. With fixed alkaline salts, assisted and moved by water and fire, by digesting, boiling, diluting, separating, and mixing. 9. With fixed acid salts, as those of alum, sulphur, and vitriol; either separately in a liquid form, or in their calxes, by diluting, boiling, distilling, digesting: or in a dry form, by calcining, roasting, burning, and distilling. 10. With volatile acid salts, by diluting, digesting, distilling and insinuating. 11. With compound salts and soaps, by calcining, subliming, distilling, and digesting, either in a dry or a liquid form. 12. With metals, by fusion and amalgamation.

In pharmacy, however, the principal menstrua are water, vinous spirits, oils, and acid and alkaline liquors.

Water is the dissolvent of all salts, vegetable gums, and of animal jellies: of the first it dissolves only a determinate quantity, though of one kind of salt more than another; and being thus saturated, leaves any additional quantity of the same salt untouched: but it is never saturated with the two latter, uniting readily with any proportions of them, and forming, with different quantities, liquors of different consistencies. When assisted by trituration, it likewise dissolves the vegetable gummy resins, as ammoniacum and myrrh; the solutions of which, though imperfect, or not transparent, but

turbid and of a milky hue, are nevertheless applicable to valuable purposes in medicine.

Rectified spirit of wine dissolves the essential oils and resins of vegetables, the pure distilled oils of animals, and soaps; though it does not act upon the expressed oil and fixed alkaline salt of which soap is made: it also, by the assistance of heat, dissolves volatile alkaline salts, but more especially the neutral ones, as the sal diureticus, &c.

Oils dissolve vegetable resins and balsams, wax, animal fats, mineral bitumens, sulphur, and certain metallic substances, particularly lead: however, the expressed oils are more powerful menstrua for most of these bodies, than the oils obtained by distillation; because the former are more capable of sustaining, without injury, a strong degree of heat, which, in most cases, is necessary to enable them to act.

Acids dissolve alkaline salts and earths, and metallic substances: however, the different acids differ greatly in their action upon these last. The vegetable acids dissolve a considerable quantity of zinc, iron, copper, and tin; and extract so much from the metallic part of antimony as to become powerfully emetic: they likewise dissolve lead, if previously calcined; but more copiously, if corroded by their steam. The marine acid dissolves zinc, iron, and copper; and though it scarce acts upon any other metallic substance, in the common way, may nevertheless be artfully combined with them all, except gold: such is the corrosive sublimate of the shops. The nitrous acid is the common menstruum of all metallic substances, except gold and the antimonial semi-metal, which are soluble only in a mixture of the nitrous and marine acids, called aqua regia. The vitriolic acid easily dissolves zinc, iron, and copper: and may be made to corrode, or imperfectly dissolve, most of the other metals.

Alkaline lixivium dissolves oils, resins, and sulphur; but their power is greatly promoted by the addition of quick-lime, as is evident in the making of soap and the common caustics. Thus assisted, they reduce the flesh, bones, and other solid parts of animals, into a gelatinous matter.

Solutions made in water and in spirit of wine, possess the virtues of the bodies dissolved: whereas oils generally blunt its activity, and acids and alkalies alter natural qualities. Hence watery and spirituous liquors are the only proper menstrua of the native virtues of vegetable and animal matters.

Most of the foregoing solutions are easily effected by pouring the menstruum on the body to be dissolved, and suffering them to stand together, for some time, exposed to a suitable warmth: a strong heat is generally necessary to enable oils and alkaline liquors to perform their office. The action of acids is usually accompanied with heat, effervescence, and a copious discharge of fumes. And as the fumes, which arise during the dissolution of some metals in

the

the vitriolic acid, prove inflammable, the operator ought to be careful, lest, by the imprudent approach of a candle, the exhaling vapour be set on fire.

Solution is much facilitated, by powdering such tenacious bodies as are friable; and slicing, or rasping, into small parts such whose texture does not admit of being powdered: this, in some cases, is of such importance, that the operation proves extremely tedious, if it be neglected. In solutions of metals, earths, or salts, with acid spirits, care should be taken not to mix them too hastily, otherwise the ebullition will cause the mixed liquor to overflow the vessels; and, in some cases, the unmanageable heat, together with the noxious fumes, will give the operator great embarrassment.

But besides the solutions made by adding fluid menstrua to the bodies to be dissolved, there is another kind, called deliquation, or solution per deliquium, in which the moisture of the air is the menstruum. It is performed by exposing the matter to be dissolved to the air, in cellars, or other damp places; for fixed alkaline and neutral salts, and some metallic salts, being thus exposed, attract its humidity, and at length become liquid. Some substances, not dissoluble by the application of water in its grosser form, as the butter of antimony, are easily liquified by this slow action of the aerial moisture.

SOLUTION, in algebra and geometry, is the answering a question, or the resolving any problem proposed.

SOLUTION of continuity, in surgery, is the separation of the natural cohesion of the solid parts of the body, by a wound.

SOLUTIVE, an appellation given to laxative and loosening medicines.

Solutive tartar is a preparation of tartar, made by boiling eight ounces of cream of tartar with four ounces of fixed salt of tartar.

SON, *filius*, an appellation given to a male child, considered in the relation he bears to his parents.

SONATA, in music, a piece, or composition, intended to be performed by instruments only; in which sense it stands opposed to cantata, or a piece designed for the voice.

SONCHUS, the sow-thistle, in botany, a genus of plants whose flower is compound and imbricated, being composed of a number of ligulated, linear, and quinque-dentated corollulæ, each containing five very short capillary filaments, topped with cylindraceous tubulous antheræ: there is no pericarpium; but the cup, which is ventricosely globular, incloses the seeds, which are oblong, crowned with a pilose down, and affixed to a naked receptacle.

The common sow-thistle flowers in May and June; and becomes a troublesome weed, if permitted to shed its seeds. It is full of a milky bitterish juice, and is accounted cooling and attenuant; and accordingly is sometimes prescribed in the stranguary,

and also in inflammations of all kinds, to be applied externally in the form of a cataplasm.

SONG, in poetry, a little composition, consisting of easy and natural verses, set to a tune in order to be sung.

The song much resembles the madrigal, and still more the ode, which is nothing but a song according to the antient rules.

SONG, in music, is applied in general to a single piece of music, whether contrived for the voice or an instrument.

SONNET, in poetry, a composition contained in fourteen verses, *viz.* two stanzas, or measures, of four verses each, and two of three; the eight first verses being all in three rhimes.

SOOT, *fuligo*, a volatile matter, arising from wood, and other fuel, along with the smoke; or rather, it is the smoke itself, fixed and gathered on the sides of the chimney.

SOPHISM, *σοφισμα*, in logic, &c. an argument which carries much of the appearance of truth, and yet leads into error.

SOPHIST, a person who uses sophisms, with a view to deceive those he would persuade or convince. See the preceding article.

SOPHISTICATION, the adulterating any thing with what is not good or genuine; a practice too common in the making up medicines for sale; as also among vintners, distillers, and others, who are accused of sophisticating their wines, spirits, oils, &c. by mixing with them cheaper and coarser materials: and, in many cases, the cheat is carried on so artfully as to deceive the best judges.

SOPHORA, in botany, a genus of plants whose flower is pentapetalous and papilionaceous. The stamina are ten distinct parallel subululated filaments, hid within the carina, and terminated with small assurgent antheræ.

The fruit is a very long and slender unilocular pod, containing a number of roundish seeds.

SOPORIFIC, or SOPORIFEROUS, medicines, are those capable of procuring sleep, as opiates, &c.

SORBUS, the service-tree, in botany, a genus of plants whose flower consists of five roundish concave petals, which are inserted in the cup, with twenty filaments, topped with roundish antheræ.

The fruit is a soft roundish umbilicated berry, containing three or four oblong cartilaginous seeds.

There are two kinds of sorbus, one called the wild-service, and the other the manured-service: the former grows naturally in many parts of England in uncultivated mountainous places, and in forests and hedges. The trunk is covered with a whitish smooth bark; but the young branches are of a brownish red colour. The leaves are winged, and composed of eight or nine pair of lobes, and terminated with a single one, and are serrated on their edges. The flowers grow in large bunches at the ends of the branches. They appear in May and

and June; and are succeeded by berries which turn red in autumn.

The other sort of service differs but little from the former, excepting the leaves, which are broader and not so much sawed. It grows wild in Italy, and other warm countries: both sorts may be propagated by sowing the seeds when the fruit is ripe, and the following autumn the plants may be transplanted in rows two feet asunder in the nursery, where they may remain three or four years, and then be replanted where they are to remain for good.

The fruit of the service is eaten in some places; and the wood of the wild sort is much commended by wheelwrights for being all heart; and it is of great use for husbandmens tools, goads, &c. It is white and smooth, and will take a tolerable polish.

**SORITES**, in logic, a species of reasoning, in which a great number of propositions are so linked together, that the predicate of the one becomes continually the subject of the next following, till at last a conclusion is formed by bringing together the subject of the first proposition and the predicate of the last: such is the following argument; 'God is omnipotent; an omnipotent being can do every thing possible; a being that can do every thing possible, can do whatever involves not a contradiction; therefore, God can do whatever involves not a contradiction.

This combination of propositions may be continued to any length we please, without in the least weakening the ground upon which the conclusion rests; and the reason is, because the sorites may be resolved into as many simple syllogisms as there are middle terms in it; and the conclusion of the last syllogism is universally found to be the same with the conclusion of the sorites.

**SORRANCE**, among farriers, a malady incident to horses: of which there are two kinds: 1. An evil counted twofold, as either an evil state or composition of a horse's body; which is to be observed either by the shape, number, quantity, or sight of the member ill affected or diseased. 2. It is used for the loosening and division of an unity, which as it may change diversely, so it has divers names accordingly; for if such a loosening and division be in a bone, then it is called a fracture; if in any fleshy part, a wound or ulcer; if in the veins, a rupture; if in the sinews, a convulsion or cramp; and if in the skin, an excoriation.

Sorrance-water is a solution of Roman-vitriol and some other ingredients, in vinegar: it is much esteemed as a remedy in many of the diseases of horses, but especially the sorrance; whence the name.

**SORREL**, *Acetosa*, in botany, a species of rumex. See the article **RUMEX**.

The common sorrel is a small plant of the fields, but in gardens it produces larger leaves; the leaves

are acid and grateful to the stomach; they are cool, and quench thirst; and their decoction makes a useful drink in fevers; it is excellent against the scurvy; and in some cold countries they employ a mixture of the juices of sorrel and scurvy-grass against this disease with success.

The round-leaved, or French sorrel, differs but little from the former, excepting the leaves, which are sometimes almost round; this is the best sort for kitchen use, for which purpose it is often cultivated in gardens, by parting the roots and planting them about a foot asunder.

**SORREL-COLOUR**, in the manege, is a reddish colour, generally thought to be a sign of a bad horse.

**SORTILEGE**, *Sortilegium*, a species of divination, performed by means of sortes or lots.

The sortes prenistinae, famous in antiquity, consisted in putting a number of letters, or even whole words, into an urn, and then, after shaking them together, they were thrown on the ground, and whatever sentences could be made out from them constituted the answer of the oracle.

Another kind of sortes consisted in taking some celebrated poet, as Homer or Virgil, and opening the book, whatever presented itself first to the eye, made the answer: and hence it got the name of sortes Homericæ, and sortes Virgilianæ, &c.

The superstitious among the ancient Christians practised a similar kind of divination, by opening the Old and New Testament; whence it got the name of sortes sanctorum.

**SORY**, or **RUSMA**, in natural history, a vitriolic mineral, formed of metalline, sulphureous, and earthy matter; being truly an ore of blue vitriol, or of the vitriol of copper alone, there not appearing to be a grain of any thing approaching to the nature of iron in it.

It is found in loose masses of different sizes, and mostly of a blackish colour, though sometimes reddish or bluish. It is found in many parts of Turkey and in Germany, where it is wrought for blue vitriol, which may be separated from it by a very easy process, by powdering the sory, then exposing it to a moist air for three or four days, and lastly, boiling it in six times its weight of water: for if this liquor be filtrated and evaporated in the usual manner to a pellicle, and then set in a cool place to shoot, there will be found crystals of pure blue vitriol adhering to the sides of the vessel.

**SOSPIRO**, in the Italian music, denotes a pause equal to the time of a crotchet.

**SOTERIA**, in antiquity, sacrifices offered to the gods for delivering a person from danger; as also poetical pieces composed for the same purpose.

**SOU**, or **SOL**, a French coin. See the article **COIN**.

**SOUGH**, among miners, denotes a passage dug under ground, to convey off water from mines.

**SOVERAIGN**, *Supremus*, strictly speaking, signifies the Supreme Being, or God. See the article **GOD**.

**SOVERAIGN**, in matters of government, is applied to the supreme magistrate, or magistrates, of an independant government or state; by reason their authority is only bounded by the laws of God, of nature, and the fundamental laws of the state: such are kings, princes, &c.

**SOVERAIGN** is also an appellation given to the supreme courts of judicature. See the article **COURT**.

**SOUL**, *Anima*, in philosophy, a spiritual substance, which animates the bodies of living creatures: it is the principal of life and activity within them. See the articles **ANIMAL**, **LIFE**, **SPIRIT**, &c.

Various have been the opinions of philosophers concerning the substance of the human soul. The Epicureans thought it a subtle air, composed of their atoms, or primitive corpuscles. The Stoics, on the contrary, maintained it was a flame, or portion of heavenly light. And the Cartesians make thinking the essence of the soul. Others, again, hold, that man is endowed with three kinds of soul, viz. the rational, which is purely spiritual, and infused by the immediate inspiration of God; the irrational or sensitive, which being common to man and brutes, is supposed to be formed of the elements; and lastly, the vegetative soul, or principle of growth and nutrition, as the first is of understanding, and the second of animal life.

Lord Bacon observes, that there are many excellencies in the human soul above those of brutes; and that where so many and such great excellencies are found, a specific difference should always be made. Hence he highly disapproves of the confused and promiscuous manner of philosophers in treating of the functions of the human soul, as if it differed in degree rather than kind from the souls of brutes. However, he allows, that the doctrine concerning the rational soul of man must be deduced from revelation: for as its substance, in its creation, was not formed out of the mass of heaven and earth, but immediately inspired by God; and as the laws of the heavenly bodies, together with those of our earth, make the subject of philosophy, so no knowledge of the substance of the rational soul can be had from philosophy. But he might have said the same of corporeal substances, since, as Mr. Locke justly observes, we have no idea of one more than of the other. See **ESSENCE**.

It is only from the primary, or essential, qualities of body, viz. extension, solidity, &c. that we form an idea of it; and why may we not frame the complex idea of a soul, or spirit, from the operations of thinking, understanding, willing, &c. which are experiments in ourselves? This idea of an immaterial substance is as clear as that we have of a material one: for though this notion of immate-

rial substances may be attended with difficulties, we have no more reason to deny or doubt of its truth, than we have to deny or doubt of the existence of the body.

That the soul is an immaterial substance appears from hence, that its primary operations of willing and thinking have not only no connection with the known properties of body, but seem plainly inconsistent with some of its most essential qualities. For the mind not only discovers no relation between thinking and the motion and arrangement of parts; but it likewise perceives that consciousness, a simple act, can never proceed from a compounded substance, capable of being divided into many parts. To illustrate this, let us only suppose a system of matter endowed with thought; then either all the parts of which this system consists, must think, which would make it not one but a multitude of distinct conscious beings; or its power of thinking must arise from the connection of the parts one with another, their motion and disposition, &c. which, all taken together, contribute to the production of thought.

But it is evident, that the motion of parts, and the manner of combining them, can produce nothing but an artful structure and various modes of motion. Hence, all machines, however artfully their parts are put together, and however complicated their structure, though we conceive innumerable different motions, variously combined, and running one into another with an endless variety, yet never produce any thing but figure and motion. If a clock, or watch, tells the hour and minutes of the day, it is only by the motion of the different hands, pointing successively at the different figures marked on the hour-plate for that purpose. We never imagine this to be the effect of thought or intelligence, nor conceive it possible, by any confinement of structure, so to improve the composition as that it shall become capable of knowledge and consciousness; and the reason is plainly this, that thought being something altogether different from motion and figure, without the least connection between them, it can never be supposed to result from them.

This, then, being evident, that intelligence cannot arise from an union or combination of unintelligent parts; if we suppose it to belong to any system of matter, we must necessarily attribute it to all the parts of which that system is composed; whereby, instead of one, we shall, as was before observed, have a multitude of distinct conscious beings. And because matter, how far soever we pursue the minuteness of its parts, is still capable of repeated divisions, even to infinity, it is plain, that this absurdity will follow us through all the suppositions that make thought inherent in a material substance. Wherefore, as consciousness is incompatible with the cohesion of solid separable parts, we are necessarily

rily led to place it in some other substance, of distinct nature and properties; and this substance we call spirit, which is altogether distinct from body, nay, and commonly placed in opposition to it: for which reason, the beings of this class are called immaterial; a word that implies nothing of their true nature, but merely denotes its contrariety to that of matter.

As to the immortality of the human soul, the arguments to prove it may be reduced to the following heads: 1. The nature of the soul itself, its desires, sense of moral good and evil, gradual increase in knowledge and perfection, &c. 2. The moral attributes of God.

Under the former of these heads it is urged, that the soul, being an immaterial intelligent substance, as has been already proved, does not depend on the body for its existence; and therefore may, nay, and must, exist after the dissolution of the body, unless annihilated by the same power which gave it a being at first; which is not to be supposed, as there are no instances of annihilation in nature. This argument, especially if the infinite capacity of the soul, its strong desire after immortality, its rational activity and advancement towards perfection, be likewise considered, will appear perfectly conclusive to men of a philosophical turn; because nature, or rather the God of nature, does nothing in vain.

But arguments drawn from the latter head, viz. the moral attributes of the Deity, are not only better adapted to convince men unacquainted with abstract reasoning, but equally certain and conclusive with the former: for as the justice of God can never suffer the wicked to escape unpunished, nor the good to remain always unrewarded; therefore, arguments drawn from the manifest and constant prosperity of the wicked, and the frequent unhappiness of good men in this life, must convince every thinking person, that there is a future state wherein all will be set right, and God's attributes of wisdom, justice, and goodness fully vindicated. We shall only add, that had the virtuous and conscientious part of mankind no hopes of a future state, they would be of all men most miserable: but as this is absolutely inconsistent with the moral character of the Deity, the certainty of such a state is clear to a demonstration.

**SOUND**, *Sonus*, a simple perfection, or idea, communicated to the soul, by means of the ear, which is the primary organ of hearing. See the article **EAR**.

Sound is caused by an undulatory, or wave-like motion of the air, arising from the tremulous motion of the parts of any sonorous body when struck upon; for those undulations, or pulses of the air, beating on the tympanum or drum of the ear, convey by the auditory nerves the sensation of sound to the mind. See the article **HEARING**.

For that sound has a necessary dependence on the air, is proved by the experiment of the bell in an exhausted receiver; and the parts of a sonorous body being put into motion by percussion, excite concentric vibrations in the air all around the said body; so that let a person be any how, or any where situated within the verge of those motions, and he will equally hear the sound, at equal distances from the body whence it comes.

**SOUND**, in music. The principal affection of sound, whereby it becomes fitted to produce harmony, and raise agreeable sensations, is that whereby it is distinguished into acute and grave; the cause of which appears to be no other than the different velocity of the vibrations of the sounding body.

**SOUND**, in geography, denotes in general any strait, or inlet, of the sea, between two headlands. However, the name Sound is given, by way of eminence, to the strait between Sweden and Denmark, joining the German ocean to the Baltic, being about four miles over.

**SOUND-BOARD**, in an organ, is a reservoir into which the wind, drawn in by the bellows, is conducted by a port-vent, and hence distributed into the pipes placed over holes in its upper-part: this wind enters them by valves, which open by pressing upon the stops or keys; after drawing the registers, which prevent the air from entering any of the pipes, except those it is required in.

**SOUNDING**, in navigation, is the trying the depth of the water, and the quality of the bottom, either by an inch or three quarter rope, with a deep sea-lead at the end of it. The sounding line or rope, is marked at two, three, and four fathoms, with a piece of black leather betwixt the strands; and, at five fathoms, with a piece of white leather, or cloth. The plummet, or lead, is usually in the form of a nine-pin, and weighs eighteen pounds; and its lower end is frequently greased, to know whether the bottom is sandy, rocky, &c. Near banks, shores, &c. they sound continually.

**SOUP**, or *Soop*, a kind of pottage made of bread and broth, or the juice of flesh, or some other matters, usually served at the beginning of a meal.

Soup is esteemed essential to a French dinner; sometimes they heighten the relish by the addition of onions, or leeks, or cabbage, &c.

**SOURIS**, in the manege, is a cartilage in the nostrils of a horse, by means of which he snorts. See the article **SNORT**.

**SOUTH**, in cosmography, one of the four cardinal points. See the article **COMPASS**.

**SOUTHERNWOOD**, *Abrotanum*, in botany, a species of artemisia. See **ARTEMISIA**.

The common southernwood rises to the height of three or four feet, having many hard brittle branches, which are full of a white pith, and of a brown

brown colour; these are furnished with many narrow leaves, which, when bruised, emit a strong odour, and have a bitterish taste: the flowers come out on the sides of the branches, and are like those of wormwood: it is easily propagated by slips or cuttings, planted in the spring, on a bed of light earth.

Southernwood is an attenuant, and is serviceable in all obstructions of the viscera, and in destroying worms; it is recommended in suppressions of urine, and against the gravel; also it is said to resist poisons, particularly from the bites of venomous creatures.

SOW, in zoology, the female of the hog-kind. See the article HOG.

Sow, in the iron-works, the name of the block or lump of metal they work at once in the iron-furnace. The size of these fows of iron is very different, even from the same workmen, and the same furnace. These furnaces having sand-stones for their hearths and sides up to the height of a yard, and the rest being made of brick, the hearth by the force of the fire is continually growing wider, so that if it at first contains as much metal as will make a sow of six or seven hundred weight, it will at last contain as much as will make a sow of two thousand weight.

SOW-BREAD, *Cyclamen*, in botany. See the article CYCLAMEN.

SOW-THISTLE, *Sonchus*, in botany. See the article SONCHUS.

SOWING, in husbandry, &c. See the article SEED, SEMINATION, &c.

One great article in sowing to advantage, Mr. Tull observes, is to know exactly at what depth the seed may be laid without danger of burying it. Seed is said to be buried, when it is laid at a depth below what it is able to come up at. Different sorts of seeds come up at different depths, some six inches and more, and others will not bear to be buried at more than half an inch. For coming at an accurate knowledge of the depth at which every seed will come up best from the sowing, Mr. Tull proposes to make gages; for the method of conducting which, we refer the reader to his own account of it, in page 58, of his Horse-hoeing Husbandry.

However, it is to be observed, that it is not proper to sow the seeds of all plants at the greatest depths at which they will come up; for it may be so deep as that the wet may rot or chill the first root, as is the case with wheat in moist land. The nature of the land, and the manner how it is laid, either flat or in ridges, and the season of sowing, with the experience of the husbandman, must determine the proper depths for different sorts of seed.

The quantity of seed is to be different also, according to the manner of the sowing. The proper quantity to be drilled on an acre is much less than

must be sown in the common way, not because hoeing will not maintain as many plants as the other, for on the contrary, it will maintain many more; but the difference is upon many other accounts, as that it is impossible to sow it so even by hand as the drill will do. For let the hand spread it ever so exactly, which yet is difficult enough to do with some seeds in windy weather, yet the unevenness of the ground will alter the situation of the seeds, the greatest part of them rebounding into holes, and the lowest places; or else the harrows, in covering, drawing them down thither; so that these low places may have ten times too much seed, and the high places may have little or none of it; and this inequality lessens in effect the quantity of the seed, because fifty seeds in room of one, will not produce so much as one will do; and where they are too thick, they cannot be well nourished, their roots not spreading to near their natural extent, for want of hoeing, to open the earth and give them way.

The distance of the rows is one extremely material point in the obtaining a good crop; but as a much larger distance is to be allowed in these than common practice has been used to, it is very difficult to persuade the farmer to venture a trial at such distances as he may have experience from.

SOWNE, a term used in the exchequer, where estreats that sowne not, are such as the sheriff by his care and diligence cannot levy, wherefore they are not regarded; and the estreats that sowne, are such as he may levy.

SPACE, *Spatium*, is defined by Mr. Locke, to be a simple idea, which we attain both by our sight and touch. The modes whereof are distance, capacity, extension, duration, &c. See the articles DISTANCE, CAPACITY, &c.

Space considered barely in length, between two bodies, is the same idea which we have of distance. If it be considered in length, breadth, and thickness, it is properly called capacity; when considered between the extremities of matter which fills the capacity of space with something solid, tangible, and moveable, it is then called extension; so that extension is an idea belonging to a body, but space, it is plain, may be conceived without it. Each different distance is a different modification of space, and each idea of any different space is a simple mode of this idea: such are an inch, foot, yard, &c. which are the ideas of certain stated lengths, which men settle in their minds for the use, and by the custom of measuring. When these ideas are made familiar to mens thoughts, they can repeat them as often as they will, without joining to them the idea of body, and frame to themselves the ideas of feet, yards, or fathoms, beyond the utmost bounds of all bodies; and by adding these still one to another, enlarge their idea of space as much as they

they please. From this power of repeating any idea of distance without ever coming to an end, we come by the idea of immensity.

Another modification of space is taken from the relation of the termination of the parts of extension, or circumscribed space, amongst themselves; and this is what we call figure. This, the touch discovers in sensible bodies, whose extremities come within our reach; and the eye takes, both from bodies and colours, whose boundaries are within its view; where observing how the extremities terminate, either in straight lines, which meet at discernible angles; or in crooked ones, wherein no angles can be perceived: by considering these as they relate to one another in all parts of the extremities of any body or space, it has that idea we call figure, which affords to the mind infinite variety. See FIGURE.

Another mode belonging to this head is, that of place.

There is another mode of space, the idea of which we get from the fleeting and perpetually perishing parts of succession, which we call duration.

Space is usually divided into absolute and relative. Absolute space is that considered in its own nature, without regard to any thing external, which always remains the same, and is infinite and immoveable.

Relative space, is that moveable dimension, or measure of the former, which our senses define by its positions to bodies within it, and this is the vulgar use for immoveable space.

Relative space in magnitude and figure, is always the same with absolute; but it is not necessary it should be so numerically; as if you suppose a ship to be, indeed, in absolute rest, then the places of all things within her will be the same, absolutely and relatively, and nothing will change its place: but suppose the ship under sail or in motion, and she will continually pass through new parts of absolute space; but all things on board, considered relatively in respect to the ship, may be, notwithstanding, in the same places, or have the same situation and position in regard to one another.

Proper and absolute motion is defined to be the application of a body to different parts of absolute, that is, infinite and immoveable space. The Cartesianists, who maintain extension the essence of matter, assert, that the space any body takes up is the same thing with the body itself; and that there is no such thing as mere space void of all matter in the universe.

SPACE, in geometry, denotes the area of any figure, or that which fills the interval or distance between the lines that terminate it.

SPACE, in mechanics, the line a moveable body, considered as a point, is conceived to describe by its motion.

SPADE, an instrument for digging up the ground, the handle or shaft whereof is about three feet long; the head is all of iron; the upper part being flat for the workman to set his foot on, to force it into the ground; the length of the head is about a foot or fifteen inches, and the breadth six or eight.

SPAGIRIC ART, *Ars Spagirica*, a name given by authors to that species of chemistry which works on the metals, and is employed in the search of the philosopher's stone.

SPAN, a measure taken from the space between the thumb's end and the tip of the little finger, when both are stretched out. The span is estimated at three hands breadth, or nine inches.

SPANIEL, in zoology, a species of the canis, or dog-kind. See the article CANIS.

There are two sorts of spaniels which necessarily serve for fowling: the first of these finds game on land, and the other on the water. Such spaniels as play their parts by land, do it either by swiftness of foot, by springing the bird, or by discovering to the fowler, by some secret sign, the place where the game lights; they serve the hawk and the net, or train.

The water-spaniel, partly by natural inclination, and partly by being well trained, has recourse to the water for his game, and by this means most of the water-fowl are taken. The size of this spaniel is somewhat larger than the other, but he is generally remarkable for long rough curling hair, which must be clipped at proper times, to render him more light for swimming.

SPAR, in natural history, a class of fossils, not inflammable nor soluble in water; when pure, pellucid and colourless, and emulating the appearance of crystal, but wanting its distinguishing characters; composed of plane and equable plates, not flexible nor elastic; nor giving fire with steel; readily calcining in a small fire, and fermenting violently with acids, and wholly soluble in them.

The spars, in general, are found in the fissure of stones, and about mines. Derbyshire affords enough of them to supply the whole world; and the German mines afford yet larger quantities.

If crystal be subject to a vast variety of appearances, so as to constitute different orders and genera, spar is much more so, there being no less than ten orders of it.

1. The pellucid, crystalliform, and perfect spars, composed of a column terminated at each end by a pyramid.
2. Those composed of two pyramids joined base to base, without any intermediate column.
3. The crystalliform columnar spars, adhering by one end to some solid body, and terminated at the other by a pyramid.
4. The pyramidal crystalliform spars without columns.
5. The spars of a parallelopiped form.
6. The spars externally of no regular form, but breaking into rhomboidal

R r

masses

masses. 7. The crustaceous spars; these are of a crystallino-terrene structure, or debased from their native pellucidity by an admixture of earth, and formed into plates or crusts of a striated figure within. 8. The crustaceous terrene spars; bodies so highly debased with earth, as to appear merely earthy, of an irregular structure, and not striated within: these often encrust fissures of stone, and sometimes vegetable and other extraneous bodies in springs. 9. The spars formed into oblong cylindric bodies, known by the name of stalactitæ, or stony icicles. 10. The spars formed into small round figures composed of various crusts inclosing one another, and generally known by the name stalagmitæ: and adding to these the spars, influenced in their figures by metalline particles, we have the whole series of these bodies, viz. 1. The cubic spars, owing their figure to lead. 2. The pyramidal spars with four planes, owing their figure to tin. 3. The rhomboidal spars, consisting of six planes, owing their figure to iron.

For medicinal use, the purest and most pellucid spars should be chosen: these perfectly dissolve in acids, and are recommended in nephritic cases. Some have used one kind, some another, as the lapis judaicus, the sparry incrustations of caverns, petrified oyster-shells, and water in which large quantities of spar are sustained. After all, the nephritic virtues of spar want sufficient proof; some even suspect its use to be more hurtful than beneficial.

It were to be wished, that whoever attempts to ascertain this point, would choose for the experiment some determinate kind of spar in its natural form, rather than under appearances, whereby its efficacy may be confounded with that of other bodies.

**SPARAGUS**, in botany. See the article **ASPARAGUS**.

**SPARGANIUM**, bur-reed, in botany, a genus producing male and female flowers on different plants; they have no corolla, and are disposed in a roundish amentum; the cup is formed of three linear deciduous leaves; and the fruit is a dry drupe, turbinate with a point, and angulated underneath: the seeds are two osseous, oblongo-ovate, and angulated nuts.

The root of this plant is recommended by Dioscorides as excellent against the poison of serpents, when taken in wine.

**SPARROW**, *Passer*, in ornithology, a species of the fringilla.

The common sparrow is the brown fringilla, with a black throat and brown temples. It is larger than the linnet, and the male is an erect and handsome bird; the head is large, the eyes small, and the beak short; the wings are short, and the tail short and forked.

The reed-sparrow, or the frangilla with a black

head, brown at the sides, and with a white ring round the neck, and a mottled back and white breast, is a very beautiful and singular bird, of the size of the common linnet; the head is small and depressed, the beak short and black, and the eyes hazle; and in most other particulars it corresponds with the common sparrow.

**SPARROW-HAWK**, in ornithology, the yellow-legged falcon, with a white undulated breast, and a fasciated brown tail.

This bird is about the bigness of a pigeon, but considerably longer bodied, in proportion to its thickness; its wings when expanded, measure twice the length of the body and tail; the tail is short but very strong, thick at the base, very sharp at the point and considerably hooked; the head is small, somewhat flattened, and of a brownish colour; the eyes are as it were sunk in the head, and their iris is yellow and bright.

**SPARROW-WORT**, *Passerina*, in botany. See the article **PASSERINA**.

**SPARSED LEAVES**, among botanists, are those which are placed irregularly about the several parts of a plant.

**SPARTIUM**, the broom-tree, in botany, a genus of plants, whose flower is pentapetalous and papilionaceous; the vexillum of which is large, almost heart-shaped, and totally reflexed; the alæ are ovate, oblong, and shorter than the vexillum; and the carina is dipetalous, lanceolated, oblong, and larger than the wings: the fruit is a long, cylindric, obtuse pod, with one cell and two valves, which include a number of round kidney-shaped seeds.

**SPARTIUM**, is also Tournefort's name for the genista of Linnæus, as is genista Linnæus's name for Tournefort's spartium. See the article **GENISTA**.

**SPASM**, *Spasma*, or *Spasmus*, in medicine. See **CONVULSION**.

A spasm, according to Hoffman, may be universal or particular, salutary or morbid. An universal spasm happens if the whole vascular genus, chiefly the heart and arteries, as also the fibres of the system, are affected, and there is a preternatural constriction therein, whereby the systole and diastole are increased, and the progress of the blood accelerated; this constitutes a fever, whereof a frequent pulse is the most certain sign.

The other kind of spasms is particular, and affects only one part of the body, which it constricts, and intercepts the free progress of the blood, rendering it unequal, and sending it in greater plenty to the other parts of the body. But particularly, this spastic affection affects the nervous and membranous parts, such as the stomach, and the whole volume of intestines; whence proceed the hysteric and hypochondriac passions. A spasm is likewise present in hæmorrhages, congestions of the blood, and unequal

equal flux of the fluid in all anxieties and suppressed excretions. See the articles HYPOCHONDRIAC, HYSTERIC, HÆMORRHAGE, &c.

If a violent spasm happens to affect the dura mater, an epilepsy or universal convulsion follows; and convulsive motions of the membranes and nerves have their origin from the medulla spinalis. A spasm is salutary when it destroys the cause of the disease, by taking away the stagnation of the humours, correcting acid caustics, and promoting the excretion of the morbid matter; but it is very pernicious when it constricts the skin and all the excretory vessels, detaining the morbid matter therein, and forcing it upon the vital parts. The causes and treatment of spasms in general, have already been treated of under the articles CONVULSION and CONVULSIVE DISORDERS.

In a spasm of the lower jaw, when the patient can neither open his mouth nor eat, as when persons are wounded, and something foreign is lodged therein, or when the nerves are hurt, or when sharp things, such as vitriol, are applied to stop the blood, the cure must be performed according to the diversity of the causes, as particularly treated of in surgery; but when this happens spontaneously in infants, it is observed that they generally die, though the best nervous and antispasmodic medicines be used.

In the cynic spasm, or, as it is otherwise called, the sardonian laughter, if it proceeds from poisons, as it generally does (especially hemlock or oenanthe) Heister directs that they be expelled immediately from the body by a vomit; then giving generous wines, warm with ginger or pepper, as was the practice of the ancients. If it happens from other causes, it must be treated with antispasmodics and nervous medicines, both inwardly and outwardly, and chiefly with plaster of betony and bayberries prepared with oil of amber, and applied to the temples and behind the ears.

SPASMODIC, something belonging to a spasm or convulsion. See the preceding article.

SPATHA, among botanists, a kind of flower-cup, which consists of a membranaceous matter growing to the stalks of some certain flowers.

This kind of cup is of various figures, often diphyllous, or divided into two parts; sometimes simple, and with others more divided: it incloses sometimes a single flower, sometimes several flowers together, and these have often no perianthium. The spatha is of very different texture and consistence in different plants. From a spatha, or sheath, proceed the flowers of the narcissus, galanthus, pancratium, arum, calla, palm, &c.

Some authors, by this word, express a rib; others, the surgical instrument called spatula; others, a sort of incision-knife, and by others it is taken for a sword, this last being, indeed, its proper signifi-

cation, and all the rest being only metaphorical applications of it to different things, which bear some resemblance to a sword.

SPATHELIA, in botany, a genus of plants, whose flower consists of five oblong equal petals, with five subulated filaments topped with ovate antheræ; the fruit is an oblong trigonal capsule, having three cells, each containing an oblong triquetrous seed.

SPAVIN, in the manege, a disease in horses, being a swelling or stiffness usually in the ham, occasioning a lameness. There are two kinds of spavins, viz. the ox-spavin, which is a callous tumour at the bottom of the ham on the inside, hard as a bone, and very painful; while it is yet recent, some only hault with it at first coming out of the stable: the other, which is the dry spavin, is more easily perceived by the horse's raising one of his hind legs with a twitch higher than the other; but sometimes it is found on both legs. This kind, which some also call stringhalt, frequently degenerates into the ox spavin, for which there is no remedy but to apply the fire, and even this is not always successful.

There are two other kinds of spavin which have their seat in the hoof, viz. the blood-spavin, being a soft tumour which grows through the horse's hoof, and is usually full of blood; the other is the bone-spavin, being a crusty substance growing on the inside of the hoof under the joint.

SPAYING, or SPADING, the operation of castrating the females of several kinds of animals, as sows, bitches, &c. to prevent any further conception, and promote their fattening.

It is performed by cutting them in the mid flank, on the left-side, with a sharp knife or lancet, taking out the uterus and cutting it off, and so stitching up the wound, anointing the part with tar, and keeping the animal warm for two or three days. The usual way is to make the incision aloope two inches and a half long, that the fore-finger may be put in towards the back to feel for the ovaries, which are two kernels as big as acorns on both sides of the uterus, one of which is drawn to the wound, the string thereof cut, and thus both taken out.

SPEAKER of the House of Commons, a member of the house elected by a majority of the votes thereof, to act as chairman or president in putting questions, reading briefs or bills, keeping order, reprimanding the refractory, adjourning the house, &c. The first thing done by the commons, upon the first meeting of a parliament, is to chuse a speaker, who is to be approved of by the king, and who, upon his admission, begs his majesty that the commons, during their sitting, may have free access to his majesty, freedom of speech in their own house, and security from arrests. The speaker

is not allowed to persuade or dissuade in passing a bill, but only to make a short and plain narrative; nor to vote unless the house be equally divided. See **PARLIAMENT**.

The lord chancellor or keeper is usually speaker of the house of lords; the speaker of the convocation is called the prolocutor. See the article **PROLOCUTOR**.

**SPEAKING**, the art or act of expressing one's thoughts in articulate sounds or words.

**SPECIALITY**, is used for a bond, bill, or other deed or instrument executed under the hand and seal of the parties thereto.

**SPECIES**, in logic, a relative term, expressing an idea which is comprized under some general one, called a genus.

The idea of a species is formed, by adding a new idea to the genus: thus if the genus be a circumscribed space, and we suppose this circumscription to be by lines, we shall obtain the notion of that species of figures which are called plane figures; but if we conceive the circumscription to be by surfaces, we get an idea of the species of solid figures. This superadded idea is called the specific difference, not only as it serves to distinguish the species from the genus; but because being different in all the several subdivisions, we thereby also distinguish the species one from another: and as this superadded conception completes the notion of the species, it is plain that the genus and specific difference are the proper and constituent parts of the species.

If we trace the progress of the mind still farther, and observe it advancing through the inferior species, we shall find its manner of proceeding to be always the same; since every lower species is formed, by superadding some new idea to the species next above: thus, if animal be the genus, by superadding the notion of four limbs, we obtain the idea of quadrupeds; if, to this, we add farther, the peculiar form and characters which distinguish mankind, we get the idea of the human species; and by adding the peculiarities which distinguish a particular person from all others, we form the notion of an individual, which is called the last species, or species specialissimum. See **DEFINITION**.

**SPECIES**, in logic, is one of the five words called by Porphyry, universals.

**SPECIES**, in rhetoric, is a particular thing, contained under a more universal one.

**SPECIES**, in optics, the image painted on the retina, by the rays of light reflected from the several points of the surface of an object.

**SPECIES**, in commerce, are the several pieces of gold, silver, copper, &c. which, having passed their full preparation and coinage, are current in public. See the article **COIN**.

**SPECIES**, in algebra, the characters or symbols made use of to represent quantities. See the article **CHARACTER**.

**SPECIES**, in pharmacy, denotes the ingredients of a compound medicine, as the diascordium in a dry form, or only reduced to powder. See **DIASCORDIUM**.

The species aromaticæ, according to the Edinburgh Dispensatory, consist of equal parts of canella, lesser cardamom-seeds, mace and ginger, reduced to powder: but the college of physicians, London, order them to be made of cinnamon two ounces; and lesser cardamom-seeds husked, ginger and long pepper, of each one ounce, all beat together into a powder. Both these compositions are agreeable, hot, spicy medicines; and as such may be usefully exhibited in cold phlegmatic habits and decayed constitutions, for warming the stomach, promoting digestion, and strengthening the tone of the viscera in general. The dose is from ten grains to a scruple and upwards.

*Change of SPECIES*, in husbandry, is the sowing first one kind of plant, then another, and then a third, and so on, upon the same land; by this means the most is made of the soil; and it is found, when it will no longer give a good crop of the first corn planted on it, that it will still give a good one of some other species; and, finally, of pease after all. After this last change of species, it is found necessary, in the common method of husbandry, to renew the land with fallowing and manure, in order to its producing any thing again.

**SPECIFIC**, in philosophy, that which is peculiar to any thing, and distinguishes it from all others.

**SPECIFIC**, in medicine, a remedy whose virtue and effect is peculiarly adapted to some certain disease, is adequate thereto, and exerts its whole force immediately thereon.

The illustrious Hoffman has given a curious account of specific medicines, but it is too long to be inserted here.

**SPECIFIC GRAVITY**, is that by which one body is heavier than another of the same dimension, and is always as the quantity of matter under that dimension. See the article **GRAVITY**.

As to the method of finding the specific gravities of bodies, see **HYDROMETER** and **HYDROSTATICAL BALLANCE**.

**SPECIOUS-ARITHMETIC**, the same with algebra. See the article **ALGEBRA**.

**SPECTACLES**, in dioptrics, a machine consisting of two lenses, set in silver, horn, &c. to assist the defects of the organ of sight. See **LENSES**.

**SPECTRE-SHELL**, *Concha Spectrorum*, a species of voluta, variegated with several reddish fasciæ or bands. See the article **VOLUTA**.

**SPECULARIS-LAPIS**, in natural history, a genus of talcs, composed of large plates visibly separate, and of extreme thinness; and each fissile again separated into a number of plates still finer. See **TALC**.

**SPECULATIVE**, something relating to the theory of some art or science, in contradistinction to practical. See the article **THEORY**.

**SPECULUM**, a looking glass, or mirror, capable of reflecting the rays of the sun, &c. See the article **MIRROR**.

**SPECULUM**, in surgery, an instrument for dilating a wound, or the like, in order to examine it attentively.

**SPEECH**, in general, the art or act of expressing a person's thoughts, by means of articulate sounds, which we call words. See the article **WORD**.

**SPEEDWELL**, *Veronica*, in botany. See the article **VERONICA**.

**SPELL**, in general, denotes the same with charm or amulet. See the articles **CHARM** and **AMULET**.

In the sea-language, the word spell signifies to do any work for a short time, and then leave it; therefore a fresh spell, is when fresh men come to work; and to give a spell, is to work in another's room.

**SPELLING**, in grammar, that part of orthography which teaches the true manner of resolving words into their syllables. See the article **ORTHOGRAPHY**.

All words are either simple or compound, as *use, disuse; done, undone*: and the rules for dividing each, must be such as are derived from the analogy of language in general, or from the established custom of speaking; which, for the English language, are reduced to the following rules: 1. A consonant between two vowels must be joined with the latter in spelling, as *na-ture, ve-ri-ly, ge-ne-rus*: except, however, the letter *x*, which is joined to the first, as in *flax-en, ox-en*, &c. and compound words, as in *up-on, un-used*, &c. 2. A double consonant must be divided, as in *let-ter, man-ner*, &c. 3. Those consonants which can begin a word, must not be parted in spelling, as in *de-fraud, re-prove, di-stinct*: however, this rule is found sometimes to fail; for though *gn* begins a word, as *gnaw, gnat*, &c. yet it must be divided in spelling, as in *cog-ni-zance, ma-lig-ni-ty*, &c. 4. Those consonants which cannot begin a word must be divided, as *ld* in *sel-dom*, *lt* in *mul-ti-tude*, *mp* in *tem-per*, *rd* in *ar-dent*; but, in final syllables, there are exceptions, as *tl* in *ti-tle*, *dl* in *han-dle*, &c. 5. When two vowels come together, and are both of them distinctly sounded, they must be separated in spelling, as in *co-e-val, mu-tu-al*, &c. 6. The grammatical terminations, or endings, must be separated in spelling, as *ed* in *wing-ed, edst* in *de-li-ver-edst, ing* in *hear-ing, ance* in *de-li-ver-ance*, &c. 7. Compound words must be resolved into their simple or component words, as *up-on, in-to, ne-ver-be-les, not-with-stand-ing*, &c.

**SPELTER**, in natural history, the same with zinc. See the article **ZINC**.

**SPENT**, in the sea language, signifies the same as broken.

**SPERGULA**, **SPURRY**, in botany, a genus of plants, whose flower consists of five ovate, concave, patent petals; with ten subulated filaments, shorter than the petals, and topped with roundish antheræ; the fruit is an ovate, close, unilocular capsule, opening with five valves, and containing many depressed globular seeds, surrounded with an emarginated border.

**SPERMA-CETI**, in pharmacy, a white flaky substance, prepared from the oil of a species of whale, called by ichthyologists, catodon, by reason it has teeth only in the under jaw. See **CATODON**.

The ignorance of the people who first used this medicine, gave it a name which seemed to express its being the semen of the whale; but it is, in reality, no more than a preparation of the oil, with which that fish abounds.

*Sperma-ceti* is a fine, bright, white, and semipellucid substance, composed of a fine surfuraceous substance, formed into oblong flakes, very light, soft, and unctuous to the touch, inflammable, soluble in oil, but not in watery menstrua; of scarce any smell, when fresh, and fine, and of a soft, agreeable, and unctuous taste. The largest, firmest, and whitest flakes of it are to be chosen. It is liable to become rancid and yellowish in keeping, and the smaller fragments contract this bad quality sooner than the larger.

The *sperma-ceti* of the shops was first made from the head of this fish; the oil obtained from its brain, and the diploe of the cranium, furnishing all that we had of it; and hence the considerable price it was long kept at. It was some time after found out, however, that any whale-oil would do as well as this, which occasioned the price to fall considerably. At present it is made in England from whale-oil of any kind, the settlings of our oilmen's larger vessels particularly, which are boiled with a lixivium of German pot-ash, or pearl-ashes, till white and firm; and after several other meltings, and a thorough separation of what saline particles might have got into the matter, it is, when cold, cut out with knives into the flakes we see it in. The process is easy, but it requires care, and a nice inspection towards the end: if not enough boiled, it is apt to turn yellow, and soon grow rancid.

*Sperma-ceti* is, therefore, oil of the animal-kind, rendered very sweet, and fit for internal use. Its virtues are emollient and pectoral; it is good in coughs and other disorders of the breast; and excellent in external applications, such as liniments, and the like: it readily dissolves in oil, or other fatty substances, for the latter purposes; and, for the former, it blends with the yolk of an egg, and after that mixture with an aqueous fluid, and makes a pleasant emulsion.

**SPERMACOCE**, **BUTTON-WEED**, in botany, a genus of plants, whose flower is monopetalous

and funnel-shaped, the tube is cylindric, narrow, and longer than the cup, and the limb is divided into four obtuse, spreading, and reflexed segments; the stamina are four subulated filaments, topped with single antheræ, and the fruit consists of two oblong capsules growing together, gibbous on one side, and flat on the other, each having two horns or points; the seeds are single and roundish. This genus being natives of Jamaica, require a stove for their preservation in this climate.

**SPERMATIC**, in anatomy, something belonging to the sperm or seed.

**SPERMATOCELE**, in medicine and surgery, the same with the circocele, or hernia varicosa. See the article **CIRSOCELE**.

**SPHACELUS**, in surgery and medicine, an absolute and perfect corruption or death of the parts; whereby it is distinguished from a gangrene, which is that very great and dangerous degree of inflammation, wherein the parts affected begin to corrupt and put on a state of putrefaction. See **GANGRENE**.

In cases of a perfect sphacelus, or mortification, wherein the parts are become absolutely dead, and wholly without sense, and soft so as to retain the impressions of one's finger-end, and are plainly fetid and corrupted, all the medicines in the world will be insufficient to restore the parts to life again; and all that remains to be done, is the one miserable remedy of preserving the rest of the body, by cutting off that part, to prevent the mortification from spreading farther. A different method, however, is to be taken in this operation, according to the degree of the symptoms and the parts affected. If only some extremity of the foot, tarsus, metatarsus, ancle, or instep, or only the bare skin and fat are sphacelated, the whole foot, in that case, ought not to be amputated, but preserving the limb entire, the surgeon is only to remove that part which is vitiated: and Heister's opinion is, that this is frequently best of all done by suppuration; or else by caustic medicines. When it is to be done by suppuration, that is to be brought on as fast as possible: and when it is done, the crust, or eschar, of the ulcer, is to be suppurated from the sound parts with proper caution. To hasten effectually a suppuration in these cases, nothing is so serviceable as the making numerous long and deep scarifications near the sound parts; and afterwards the incised parts are to be well anointed with the common digestive ointment, and after that treated with the balsamic cataplasms and fomentations, in common use on the like occasions. A fomentation also serviceable in these cases, is made by mixing, in a quart of a decoction of scordium, or of barley-water, vinegar of rue, six ounces; spirit of wine with Venice-treacle, four ounces; and an ounce or two ounces of common salt; this is to be applied hot, with compresses to the incised part,

and frequently repeated till the disorder appears to spread no farther, which is known to be the case, when the tumour of the vitiated part subsides, and the edges of the sound part become tumid all round; and the second or third day after this, a suppuration is usually formed, and the sound parts become gradually separated from the vitiated. After this, to soften and promote a speedy separation of the eschar, the following cataplasm is always found highly serviceable: take of scordium, two handfuls; mallows, marsh-mallows, and henbane, of each one handful; lavender flowers half an handful: let these be boiled to the consistence of a cataplasm in vinegar or oxycrate; and when in that state, add to them three ounces of the flower of linseed, one ounce of linseed oil, and two ounces of sal armoniac. This is to be applied warm over the whole, and is to be retained in that condition, as long as shall be found necessary, by means of a brick boiled in water, and applied wrapped in a linen-cloth, or some other like means. See **SUPPURATION** and **FOMENTATION**.

After these medicines have been used, and the whole surrounding skin is gently tumefied with redness, a crust or eschar is then formed by degrees, and the sound flesh begins to separate from the rest; by this we know that the disorder has done spreading, and that an entire suppuration of the vitiated parts will very shortly follow. When this separation shews itself beginning, it should be promoted as much as possible, by dressing the part with the common digestive, either alone, or mixed with Venice-treacle, which must be retained on between the sound and the dead parts. To make way for this, it is sometimes necessary to divide them a little by the lancet; and when that is done, and the dressing has been applied, the before-described cataplasm should be laid on warm; and in all the succeeding dressings, whatever is found loose of the dead part must be carefully removed. And if it be necessary, from the adhesion of the vitiated parts to the sound, to use the scissors, or scalpel, to divide them, this is always to be done with very little either of pain or danger; it will then be proper to dress the part with the digestive, and a plaster of diachylon, or the like, over it, till the corrupted parts are entirely cast off, and the ulcer appears perfectly well cleansed, and the cure is then easily perfected in the common way.

**SPHÆRANTHUS**, globe-flower, in botany, a genus of plants, whose flower is composed of female and hermaphrodite corollulæ, included in a globose imbricated cup; the hermaphrodite florets are barren and placed in the disc; they are monopetalous and funnel-shaped; the female florets are placed round the border, and are tubulated, with the mouth cut into three small segments; there is no pericarpium, but the cup contains the seeds, which are oblong, naked, and placed on a squamous receptacle.

**SPHÆROCARPUS**, in botany, a genus of the cryptogamia class of plants, consisting of foliaceous matter, expanded on the ground, and producing very large and obvious fructifications.

Dr. Hill thinks it probable, that the male flowers are produced on separate plants from the female, and have not been discovered to belong to the same species: no male parts of fructification are described to us; the female parts consist of a tubulated and inflated vagina, within which are contained a large globular capsule, containing a great number of small loose seeds.

**SPHÆROMACHIA**, *σφαίρομαχία*, in antiquity, a particular kind of boxing, wherein the combatants had balls of stone, or lead, in their hands, which were called *σφαίραι*; hence the seventh part of the gymnasium, where this exercise was practised, was called the sphæristerium.

**SPHAGNUM**, in botany, a genus of mosses, consisting of stalks furnished with leaves; there is neither calyx or corolla, but a small membrane runs into the anthera and receptacle; the anthera is globose, with its mouth intire, and the receptacle is margined, obsolete, and under the anthera.

**SPHENOIDAL SUTURE**, in anatomy, a suture thus called from its encompassing the os sphenoides, which it separates from the os frontis, the os petrosum, and the os occipitis. See **SKULL**, and the next article.

**SPENOIDES**, or **Os CRUCIFORME**, in anatomy, the seventh bone of the cranium, or skull.

**SPHENOPHARYNGÆUS**, in anatomy, a pair of muscles, called also the pterygopharyngæus. See **PTERYGOIDÆUS**.

**SPHENOSTAPHYLINUS**, in anatomy, a muscle of the larynx. It descends from a round fleshy origination, near the root of a process of the os sphenoides, and from thence runs obliquely to the uvula, and is inserted into its hinder and upper part, where it joins its partner.

It serves to draw the uvula upwards and backwards, and hinders the masticated aliment from passing into the foramina narium, in deglutition.

**SPHERE**, *Sphæra*, *σφαίρα*, is a solid contained under one uniform round surface, such as would be formed by the revolution of a circle, about a diameter thereof, as an axis.

*Properties of the SPHERE.* 1. All spheres are to one another as the cubes of their diameters. 2. The surface of a sphere is equal to four times the area of one of its great circles, as is demonstrated by Archimedes in his book *Of the Sphere and cylinder*, lib. i. prop. 37. hence, to find the superficies of any sphere, we have this easy rule; let the area of a great circle be multiplied by 4, and the product will be the superficies: or, according to Euclid, lib. vi. prop. 20. and lib. xii. prop. 2. the area of a given sphere, is equal to that of a circle, whose radius is equal to the diameter of the sphere. There-

fore, having measured the circle described with the radius, this will give the surface of the sphere. 3. The solidity of a sphere is equal to the surface multiplied into one third of the radius: or, a sphere is equal to two thirds of its circumscribing cylinder, having its base equal to a great circle of the sphere.

**SPHERE**, in astronomy, that concave orb, or expanse, which invests our globe, and in which the heavenly bodies appear to be fixed, and at an equal distance from the eye.

The better to determine the places of the heavenly bodies in the sphere, several circles are supposed to be described on the surface thereof, hence called the circles of the sphere: of these, some are called great circles, as the equinoctial, ecliptic, meridian, &c. and others, small circles, as the tropics, parallels, &c. See each under its proper article.

**Armillary SPHERE.** See the article **ARMILLARY SPHERE**.

**SPHERE of Activity of a Body**, is that determinate space or extent, to which, and no farther, the effluvia continually emitted from that body, reach; and where they operate according to their nature. See the article **POWER**.

**SPHERICS**, is that part of geometry which treats of the position and mensuration of arches of circles, described on the surface of a sphere.

**SPHEROID**, in geometry, a solid, approaching to the figure of a sphere.

The spheroid is generated by the entire revolution of a semi-ellipsis about its axis. See the article **EL-LIPSIS**.

**SPHINCTER**, in anatomy, a term applied to a kind of circular muscles, or muscles in form of rings, which serve to close and draw up several orifices of the body, and prevent the excretion of the contents: thus the sphincter of the anus closes the extremity of the intestinum rectum.

The sphincter of the bladder is composed of a series of transverse fibres running crosswise, under the strait fibres of the neck of the bladder, in form of a circle, and serving to close it, to prevent the involuntary discharge of the urine.

The sphincter of the pupil of the eye appears upon the posterior surface of the uvea when its blackness is cleared away, and is formed of circular fibres for contraction, as the ciliary fibres are for the dilatation of the pupil.

The sphincter of the vagina is composed of a series of muscular fibres arising from the sphincter of the anus, and surrounds the orifice of the vagina.

**SPHINX**, *σφιγξ*, in sculpture, &c. a figure or representation of a monster of that name, famed among the antients, now mostly used as an ornament in gardens, terraces, &c. It is represented with the head and breasts of a woman, the wings of a bird, the claws of a lion, and the rest of the body like a dog. It is supposed to have been engendered

gendered by Typhon, and sent by Juno to be revenged on the Thebans. Its office, they say, was to propose dark enigmatical questions to all passers by; and if they did not give the explication thereof, to devour them. It made horrible ravages, as the story goes, on a mountain near Thebes, and could not by any means be destroyed, till after Œdipus had solved the following riddle, "What animal is it that in the morning walks on four legs, at noon on two, and at night on three?" The answer was "Man."

Among the Egyptians, the sphinx was the symbol of religion, by reason of the obscurity of its mysteries: and on the same account the Romans placed a sphinx in the porch of their temples.

**SPICA VIRGINIS**, a star of the first magnitude, in the constellation virgo. See **VIRGO**.

**SPIDER**, *aranea*, in zoology, an insect of a roundish or elliptic figure, having eight eyes placed on the hinder part of the thorax, and having also eight legs. This creature has a power of spinning.

The species of spiders are very numerous; but authors have made them more so, by admitting among them other insects of a very different genera.

**SPIDER-WORT**, *phalangium*, in botany, a genus of plants whose flower consists of six oblong, blunt, spreading petals; and six subulated erect filaments, topped with small incumbent furrowed antheræ.

The fruit is a smooth, ovate, three furrowed capsule, containing a number of angulated seeds.

This genus is comprehended among the anthericum by Linnæus.

**Virginia SPIDER-WORT**. See the article **TRASCANTIA**.

**SPIEL**, in the glass-trade, an iron-instrument, hooked at the end and pointed, with which the workmen take the metal up out of the melting-pots, for proofs or essays, to see whether it be fit for work.

**SPIGELIA**, worm-grass, in botany, a genus of plants whose flower is monopetalous and funnel-shaped. The tube is much longer than the cup; and is narrower below than above: and the limb is quinquefid and spreading. The stamina are five in number; and the fruit consists of two globose capsules, which join together, and are placed on the cup. The seeds are roundish, very small and numerous.

This genus are natives of North America, and is much esteemed there for its efficacy in destroying worms, for which purpose it has been long used by the inhabitants of Brasil, and also by the negroes, who taught the inhabitants of the British islands in America the use of it.

**SPIGEL**, *meum*, in botany, a genus of umbelliferous plants, the general corolla of which is uniform. The partial one consists of five inflexo-cordated, unequal petals. There is no pericarpium. The fruit is oblong, striated, and divisible in two

parts. The seeds are two; oval, striated, convex on one side, and plane on the other.

This genus is called *athamanta* by Linnæus.

The root of spigal is used in medicine. It is about the thickness of the little finger, branched, and covered with a bark of a ferruginous colour; but is pale within, a little gummous, and contains a whitish pith. It smells almost like parsnips, though more aromatic; and the taste is not disagreeable, though it is acrid and a little bitter. It is dry and carminative, expelling wind, and helping the cholic and gripes: it is also alexipharmic, and good against pestilential distempers, being an ingredient in the theriaca and mithridate: it is also reckoned good against the stone, and for stoppages of the urine.

**SPIKE**, or *oil of SPIKE*, a name given to an essential oil distilled from lavender, and much used by the varnish makers, and the painters in enamel, and of some use in medicine.

**SPIKENARD**, *nardus*, in botany. See the article **NARDUS**.

**Ploughman's SPIKENARD**, in botany, the same with the conyza, or flea-bane. See the article **CONYZA**.

**SPINA BIFIDA**, in anatomy, a parting of the spinal processes into two rows: the existence of such a case is doubted. See the article **SPINE**.

**SPINA VENTOSA**, in surgery and medicine, that species of corruption of the bones which takes its rise in the internal parts, and by degrees enlarges the bone, and raises it into a tumour, and which, when it happens to children, is termed by Severinus, and many others, *pædarthrocaces*.

**SPINACH**, or **SPINAGE**, *Spinacia*, in botany, a genus producing male and female flowers on different plants. The male flower has no corolla; but the cup is divided into five oblong, obtuse, concave segments; and contains five capillary filaments, topped with oblong twin antheræ. The cup of the female flower is divided into four parts. The corolla is wanting. It contains a roundish compressed germen, which supports four capillary styles, which are each crowned with a single stigma. The seed is inclosed in the cup; and is either of a roundish form, or armed with two or three thorns.

There are two kinds of spinach cultivated in gardens for culinary purposes; and are distinguished by gardeners by the title of prickly spinach, and round leaved spinach. They are both propagated from seeds: the former is sown in August for winter and spring use, which when come up, should be hoed out about three or four inches distance, and, if necessary, repeated a second time, and by having a sufficient quantity, will be fit for use all the winter, observing to crop the larger leaves as they are wanted. The other sort of spinach has rounder leaves, and the seeds are without prickles: this is not so hardy as the winter sort; it is therefore more commonly sown in the spring, on an open spot of ground,

Fig.1. Winding of Silk.

Fig.2.

Siphons.

Fig.3.

Fig.4. Spiral.

Fig.5. Spout.

ground, and when the plants are up should be hoed out as the former; but as they soon run up to seed, and are then unfit for use, it is therefore necessary for their longer continuance to sow at four different seasons in the spring, *viz.* January, February, March, and April, after which time they run to seed almost as soon as the plants are up, particularly in dry weather.

Spinach is said to temperate acrid bilious humours in the first passages; but as it is watery, some correct it with salt, pepper, and other spices. It does not yield much nourishment; but it is not unwholesome, and generally keeps the body open.

It is not used in medicine, except in counterfeiting the colour of some things of value, as particularly giving to Gascoign's powder the same colour as is given by bezoar.

SPINALIS, in anatomy, the names of several muscles, &c. of the spine, but more particularly that of a muscle on the side of the neck, arising from the five superior processes of the vertebræ of the thorax, and the inferior of the neck; and which in its ascent, becoming more fleshy, is inserted into the inferior part of the vertebræ of the neck laterally. It serves to draw the neck backwards.

SPINDLE, in the sea-language, is the smallest part of a ship's capstan, which is betwixt the two decks. The spindle of the jeer-capstan has whelps to heave the viol.

The axis of the wheel of a watch or clock, is also called the spindle. Among miners, the spindle is a piece of wood fastened into either stow-blade.

SPINDLE-TREE, *Euonymus*, in botany. See the article EUONYMUS.

SPINE, SPINA-DORSI, in anatomy, the bony column reaching from the head down to the anus; being the series or assemblage of vertebræ which sustain the rest of the body, contain the spinal marrow, and to which the ribs are connected.

SPINET, or SPINNET, a musical instrument ranked in the second or third place among harmonious instruments. It consists of a chest or belly made of the most porous and resinous wood to be found, and a table of fir glued on slips of wood called summers, which bear on the sides. On the table is raised two little prominences or bridges, wherein are placed so many pins as there are chords or strings to the instrument. It is played on by two ranges of continued keys, the former range being the order of the diatonic scale, and that behind, the order of the artificial notes or semi-tones. The keys are so many flat pieces of wood, which, touched and pressed down at the end, make the other raise a jack which strike and sound the strings by means of the end of a crow's quill wherewith it is armed. The thirty first strings are of brass, the other more delicate ones of steel or iron-wire; they are all stretched over the two bridges already mentioned. The figure of the spinet is a long square or paral-

lelogram; some call it an harp-couched, and the harp an inverted spinet.

SPINNING, in commerce, the act or art of reducing silk, flax, hemp, wool, hair, or other matters, into thread. Spinning is either performed on the wheel with a distaff and spindle, or with other machines proper for the several kinds of working. Hemp, flax, nettle-thread, and the like vegetable matters, are to be wetted in spinning; silks, wools, &c. are to be spun dry, and do not need water; but there is a way of spinning silk as it comes off the cafes or balls, where hot and even boiling water is to be used.

SPINOSE LEAVES, among botanists, are those whose surfaces or edges are armed with cartilaginous points, and so firmly affixed, that they cannot be separated without injuring the body of the leaves: such are those of the holly-tree, &c.

SPINOZISM, or SPINOSISM, the doctrine of Spinoza, or atheism and pantheism proposed after the manner of Spinoza, who was born a Jew at Amsterdam.

The great principle of Spinozism, is that there is nothing properly and absolutely existing besides matter and the modifications of matter; among which are even comprehended thought, abstract and general ideas, comparisons, relations, combinations of relations, &c.

SPINSTER, in law, an addition usually given to all unmarried women from the viscount's daughter downwards; but, according to Sir Edward Cooke, *generosa* is a good addition for a gentlewoman; and that if such a person be named spinster in any original writ, appeal, or indictment, she may abate and quash the same.

SPIRÆA, in botany, a genus of plants whose flower is rosaceous; and consists of five oblong, roundish, petals, which are inserted in a monophyllous cup. The filaments are slender; and twenty or more in number; and terminated with roundish antheræ. The germina are five or more in number, supporting as many slender styles, which are crowned with capitated stigmata. The fruit is an oblong, compressed, acuminate capsule, formed of two valves, containing a few small acuminate seeds.

This genus includes the common spiræa frutex and Hypericum frutex, to which Linnæus has added the filipendula, ulmaria, and barba capræ of Tournefort.

SPIRAL, in geometry, a curve line of the circular kind, which, in its progress, recedes from its center.

A spiral, according to Archimedes, its inventor, is thus generated: if a right line, as AB (Plate LXXXIII. fig. 4.) having one end fixed at B, be equally moved round, so as with the other end A to describe the periphery of a circle; and, at the same time, a point be conceived to move forward

ward equally from B towards A, in the right-line B A, so as that the point describes that line, while the line generates the circle: then will the point, with its two motions, describe the curve-line B 1, 2, 3, 4, 5, &c. which is called the helix or spiral line; and the plane space, contained between the spiral line and the right line B A, is called the spiral space.

If also you conceive the point B to move twice as slow as the line A B, so as that it shall get but half way along the line B A, when that line shall have formed the circle; and if then you imagine a new revolution to be made of the line carrying the point, so that they shall end their motion at last together, there will be formed a double spiral line, and the two spiral spaces, as you see in the figure. From the genesis of this curve, the following corollaries may be easily drawn. 1. The lines B 12, B 11, B 10, &c. making equal angles with the first and second spiral (as also B 12, B 10, B 8, &c.) are in arithmetical proportion. 2. The lines B 7, B 10, &c. drawn any how to the first spiral, are to one another as the arches of the circle intercepted between B A and those lines. 3. Any lines drawn from B to the second spiral, as B 18, B 22, &c. are to each other as the aforesaid arches, together with the whole periphery added on both sides. 4. The first spiral space is to the first circle as 1 to 3. And, 5. The first spiral line is equal to half the periphery of the first circle; for the radii of the sectors, and consequently the arches, are in a simple arithmetic progression, while the periphery of the circle contains as many arches equal to the greatest; wherefore the periphery to all those arches is to the spiral lines as 2 to 1.

**SPIRAL**, in architecture and sculpture, implies a curve that ascends, winding about a cone or spire, so as all the points thereof continually approach the axis. It is distinguished from the helix, by its winding around a cone, whereas the helix winds in the same manner around a cylinder.

**Proportional SPIRALS**, are such spiral lines as the rhumb lines on the terrestrial globe, which, because they make equal angles with every meridian, must also make equal angles with the meridians in the stereographic projection on the plane of the equator; and therefore will be, proportional spirals about the polar point.

**SPIRE**, *spira*, in architecture, was used by the antients for the base of a column, and sometimes for the astragal or tore. But, among the moderns, it denotes a steeple that continually diminishes as it ascends, whether conically or pyramidally.

**SPIRIT**, *spiritus*, in metaphysics, an incorporeal being of intelligence; in which sense, God is said to be a spirit, as are angels and the human soul.

**SPIRIT**, in chemistry, a name applied to several very different substances; however, in general, it denotes any distilled volatile liquor that is not infi-

pid, as phlegm, or pure water, nor inflammable as oil: but under this general idea are comprehended liquors of quite opposite natures, some being acid, and others alkaline; which last are such enemies to the former, that as soon as they are put together they raise a violent effervescence, and grow hot: and to these may be added a third sort, called vinous or inflammable spirits; which though very subtle and penetrating, are not manifestly either acid or alkaline.

**SPIRITS**, or **ANIMAL SPIRITS**, in physiology. See **ANIMAL SPIRITS**.

**SPIRITUAL**, in general, something belonging to, or partaking of, the nature of spirit.

**SPIRITUALITIES** of a *Bishop*, are the profits that he receives as a bishop, and not as a baron of parliament; such are the duties of his visitation, presentation-money, what arises from the ordination and institution of priests, the income of his jurisdiction, &c.

**SPITTLE**, *Saliva*, in physiology. See the article **SALIVA**.

**SPLACHNUM**, in botany, a genus of mosses, the male flower of which is pedunculated, the cup is a smooth conic calyptra; the anthera is cylindric, and opening into eight reflexed dentules at its mouth, but is destitute of a ring, under it is a large coloured membranaceous receptacle; the cup of the female flower is star-shaped, composed of many subulated folioles, placed in an imbricated manner, and contains a number of short, coloured, fastigate, central pistils.

**SPLEEN**, *σπλην*, *Lien*, in anatomy, is a viscus of a deep blackish-red colour, situated on the left side of the stomach, under the diaphragm, near the ribs, and above the left kidney. Its figure is somewhat uncertain; but is usually like that of a tongue, being hollow towards the stomach, and convex towards the diaphragm and ribs: however, it is often irregular, and has in many parts fissures. It is connected with the stomach, by the *vasa brevia*, and with the pancreas, omentum, the diaphragm, and left kidney by membranes. Its size is various, usually five or six inches long, three broad and one inch thick, in the human body: in dogs, hogs, and many other animals, it is much larger and thinner.

**SPLEEN-WORT**, *Lonchitis*, in botany. See the article **LONGCHITIS**.

**SPLENETIC**, a person affected with obstruction of the spleen.

**SPLENIC-VESSELS**, the artery and vein of the spleen.

**SPLENIUS**, in anatomy, a pair of the extensor muscles of the head, which rising from the lower vertebra of the neck, and the five upper ones of the back, is inserted a little above the mastoid processes. See the article **MUSCLE**.

**SPLENT**,

**SPLENT**, or **SPLINT**, among farriers, a calous, insensible excrescence, breeding on the shank-bone of horses; which, when it grows big, spoils the shape of the leg, and generally comes upon the inside: but if there be one opposite to it on the outside, it is called a peg, or pinned splent; because it does, as it were, pierce the bone, and is extremely dangerous.

The simple splents are only fastened to the bone, at a pretty distance from the knee, and without touching the back sinew, and have not a very bad consequence; but those that touch the back sinew, or are spread on the knee, will make a horse lame in a short time.

For the cure of this malady, shave away the hair, and rub and beat the swelling with the handle of a shoeing hammer; then having burnt three or four hazle sticks, while the sap is in them, chafe the splent with the juice, or water that issues out at both ends, applying it as hot as you can, without scalding the part: after that, rub or bruise the swelling with one of the sticks, and continue frequently to throw the hot juice upon the part, but so as not to scald it, and continue still rubbing it, till it grows soft. Then dip a linen-cloth, five or six times double in the hazel-juice, as hot as your hands can endure it, and tie it upon the splent, where let it remain for twenty four hours, keeping the horse in the stable for the space of nine days, not suffering him to be either ridden or led to water; by which time the splent will be dissolved, and the hair will afterwards grow on it again.

**SPLENTS**, or **SPLINTS**, in surgery, pieces of wood, used in binding up broken limbs.

**SPLICING**, in the sea language, is the untwisting the ends of two cables or ropes, and working the several strands into one another by a fidd, so that they become as strong as if they were but one rope. See **CABLE**, &c.

**SPODIUM**, in pharmacy, one of the foulest rements of copper; being nothing but the worst and heaviest parts of the cadmia ostracitis, thrown up in such coarse pieces by the blast of the bellows, that it does not adhere to the roof or sides of the furnace, but falls down again into several parts of the furnace; and being collected along with many other kinds of foulnesses, in form of a blackish heavy matter, is indeed no better than the sweepings of the furnaces, where the copper is refined.

**SPOILS**, *Spolia*, whatever is taken from the enemy, in time of war.

**SPONDEE**, *Spondeus*, in ancient poetry, a foot consisting of two long syllables, as *omnes*. See the article **FOOT**.

**SPONDIAS**, Brazilian plum, in botany, a genus of plants, whose flower consists of five oblong, plane, patent petals; the stamina are composed of ten subulated filaments, shorter than the corolla, but alternately longer; these are topped with ob-

long antheræ: the fruit is a large oblong drupe, containing an ovate, ligneous, fibrous drupe, having five angles and five cells.

**SPONDYLUS**, in anatomy, a name anciently given to a vertebra of the spina dorfi.

**SPONGIOSE**, in anatomy, an appellation given to several parts of the body, on account of their porous and cavernous texture, not unlike that of sponge; as the spongiose or ethmoide bone of the nose, the spongiose bodies of the penis. See **NOSE** and **PENIS**.

**SPONSORS**, among Christians, are those persons, who, in the office of baptism, answer, or are sureties, for the persons baptized.

**SPONTANEOUS**, a term applied to such motions of the body, and operations of the mind, as we perform of ourselves, without any constraint.

**SPOONWORT**, *Cochlearia*, in botany. See the article **COCHLEARIA**.

**SPOONING**, in the sea-language, is said of a ship, which, being under sail in a storm at sea, is unable to bear it, and consequently forced to put right before the wind.

**SPORADES**, among ancient astronomers, a name given to such stars, as were not included in any constellation.

**SPORADIC DISEASES**, among physicians, are such as seize particular persons at any time or season, and in any place; in which sense they are distinguished from epidemical and endemic diseases; the former whereof are peculiar to certain times or seasons, and the latter to certain places or countries.

**SPOTS**, in astronomy, certain places of the sun's or moon's disc, observed to be either more bright, or darker, than the rest; and, accordingly, called *faculae* and *maculae*.

**SPOUT**, or **WATER-SPOUT**, in natural history, an extraordinary and dangerous meteor, observed at sea, and sometimes at land, called by the Latins *typho* and *sipho*. Its first appearance is in form of a deep cloud, the upper part of which is white, and the lower black: then from the lower part of this cloud hangs, or rather falls down, what is properly called the spout, in form of a conical tube, biggest at top; and under this tube, there is always a great boiling and flying up of the water of the sea, as in a jet d'eau. For some yards above the surface of the sea, the water stands as a column or pillar, from the extremity whereof it spreads and goes off, as in a kind of smoke. Frequently, the cone descends so low, as to touch the middle of this column, and continue for some time contiguous to it; though sometimes it only points to it, at some distance, either in a perpendicular or oblique line. Frequently it is scarce distinguishable, whether the cone or the column appear the first, both appearing all of a sudden against each other. But sometimes the water boils up from the sea to a great height, with-

without any appearance of a spout pointing to it, either perpendicularly or obliquely. Indeed, generally, the boiling or flying up of the water has the priority, this always preceding its being formed into a column. Generally, the cone does not appear hollow, till towards the end, when the sea-water is violently thrown up along its middle, as smoke up a chimney. Soon after this, the spout or canal disappears; the boiling up of the water, and even the pillar, continuing to the last, and for some time afterwards; sometimes till the spout form itself again, and appear a-new; which it sometimes does several times in a quarter of an hour. See plate LXXXIII. fig. 5.

**SPRAT**, in ichthyology, a species of clupea, with the lower jaw longest, and the belly very acute.

The sprat has been generally, but erroneously, supposed a herring, not grown to its full size; its usual length is about four or five inches, and its breadth somewhat more, in proportion, than in the herring; there is a spot on each side, near the extremity of the coverings of the gills. It is caught in most of our seas, and brought in surprising quantities to London.

**SPRING**, *Fons*, in natural history, a fountain, or source of water, rising out of the ground.

Various have been the opinions of philosophers concerning the origin of springs; but those which deserve notice, are only the three following ones:

1. That the sea-water is conveyed through subterraneous ducts, or canals, to the places where the springs flow out of the earth: but as it is impossible that the water should be thus conveyed to the tops of mountains, since it cannot rise higher than the surface, some have had recourse to subterraneous heats; by which, being rarified, it is supposed to ascend in vapours through the bowels of the mountains. But as no sufficient proof is brought of the existence of these central heats, or of caverns in the mountains big enough to let the vapours ascend, supposing such heats, we shall not take up our reader's time with a formal refutation of this hypothesis.

2. As to those who advance the capillary hypothesis, or suppose the water to rise from the depths of the sea through the porous parts of the earth, as it rises in capillary tubes, or through sand or ashes, they seem not to consider one principal property of this kind of tube, or this sort of attraction; for though the water rise to the top of the tube or sand, yet it will rise no higher, because it is by the attraction of the parts above that the fluid rises, and where that is wanting it can rise no farther. Therefore, though the waters of the sea may be drawn into the substance of the earth by attraction, yet it can never be raised by this means into a cistern, or cavity, to become the source of springs.

3. The third hypothesis is that of the sagacious naturalist, Dr. Halley, who supposes the true sources

of springs to be melted snow, rain-water, dew, and vapours condensed.

Now, in order to prove that the vapours, raised by the heat of the sun, from the surface of the seas, lakes, and rivers, are abundantly sufficient to supply the springs and rivers with fresh water, the doctor made the following experiment: he took a vessel of water, made of the same degree of saltness with that of the sea, by means of the hydrometer; and having placed a thermometer in it, he brought it, by means of a pan of coals, to the same degree of heat with that of the air in the hottest summer. He then placed this vessel, with the thermometer in it, in one scale, and nicely counterpoised it with weights in the other; after two hours, he found, that about the sixtieth part of an inch was gone off in vapour, and consequently in twelve hours, the length of a natural day, one-tenth of an inch would have been evaporated.

From this experiment it follows, that every ten square inches of the surface of the water yield a cubic inch of water in vapour per day, every square mile 6914 tons, and every square degree (or 69 English miles) 33 millions of tons. Now, if we suppose the Mediterranean to be 40 degrees long, and four broad, at a medium, which is the least that can be supposed, its surface will be 160 square degree, from whence there will evaporate 5280 millions of tons per day, in the summer-time.

The Mediterranean receives water from the nine great rivers following, viz. the Iberis, the Rhine, the Tyber, the Po, the Danube, the Neister, the Borysthenes, the Tanais, and the Nile; all the rest being small, and their water inconsiderable.

Now, let us suppose, that each of these rivers conveys ten times as much water to the sea as the Thames, which, as is observed, yields daily 76,032,000 cubic feet, which is equal to 203 millions of tons; and therefore all the nine rivers will produce 1827 millions of tons, which is little more than one-third of the quantity evaporated each day from the sea. The prodigious quantity of water remaining, the doctor allows to rains, which fall again into the seas, and for the uses of vegetation.

As to the manner in which these waters are collected, so as to form reservoirs for the different kinds of springs, it seems to be this: the tops of mountains, in general, abound with cavities, and subterraneous caverns formed by nature to serve as reservoirs; and their pointed summits, which seem to pierce the clouds, stop those vapours which fluctuate in the atmosphere, and being condensed thereby, they precipitate in water, and by their gravity, easily penetrate through beds of sand and lighter earth, till they are stopped in their descent by more dense strata, as beds of clay, stone, &c. where they form a basin, or cavern, and work a passage horizontally, and issue out at the side of the mountain.

Many

Many of these springs running down by the valleys, between the ridges of hills, and uniting their streams, form rivulets or brooks; and many of these, again, uniting on the plain, become a river.

*Medicinal Virtues, &c. of SPRINGS.* These are owing to the different qualities and temperament of the strata through which these waters may be collected, or pass; if those reservoirs of water in the body of mountains be situated where mineral ores abound, or the ducts and feeding streams run thro' mineral earths, it is easy to conceive that particles of metal will mix with, and be absorbed by, the water, which being saturated therewith, becomes a mineral spring, or well.

If salt, sulphur, lime-stone, &c. abounds in the strata, through which the water passes, it will then be saline, sulphureous, lime-water, &c. If sulphur and iron should both abound in the parts of the hill, whence the waters come, the waters will partake of the warmth or heat which is occasioned by the mixture of two such substances in the earth, where they are found. See MINERAL WATERS, CHALYBEATE WATERS, SEA WATER, BATH WATERS, &c.

*SPRING, Ver,* in cosmography, implies one of the seasons of the year; commencing, in the northern parts of the world, on the day the sun enters the first degree of Aries, which is about the twenty-first of March, and ending when the sun leaves Gemini.

*SPRING, Elater,* in mechanics, denotes a thin piece of tempered steel, or other elastic substance; which, being wound up, serves to put several machines in motion by its elasticity, or endeavour to unbend itself: such is the spring of a clock, watch, and the like.

The spring of a lock, gun, pistol, or the like, is a piece of steel, violently bent; which, being set at liberty, beats back the bolt of the lock, or strikes down the cock.

*SPRING-TIDE.* See the article TIDE.

*SPRINGE,* among sportsmen, a device made of twisted wire, to catch birds or small beasts.

*SPRINGING of a Mast,* in the sea-language, is when it cracks, but is not quite broken in any part of it; as the partners, hounds, &c.

*SPRINGY BODIES,* the same as elastic ones; or such as, having had their figure changed by the stroke of another body, can recover again their former figure, which bodies not elastic cannot do. See the article ELASTICITY.

*SPUNGE, Spongia,* in botany, a genus of submarine plants, belonging to the cryptogamia lithophyta class: it consists of a soft, tough, and elastic matter, formed usually into rude masses of a cavernous structure, and having very little of the appearance of plants.

Upon a nice examination, sponge appears to be composed of capillary fibres, which are hollow and implicated in a surprising manner; and are surrounded by thin membranes which arrange them into a cellular form. This structure, no less than the constituent matter, of sponge, renders it the fittest of all bodies to imbibe a great quantity of any fluid, and upon a strong pressure, to part with almost the whole quantity again.

Sponge, calcined to a blackness, and reduced to powder, has been lately brought into great use as a sweetner of the blood, and a diuretic: some have pretended even to cure leprosy with it, and others have extolled it against the bite of a mad dog; but these are virtues less certainly known of it.

In the larger and coarser pieces of sponge, there are often small stones found imbedded in the substance of the matter; and yet, more frequently, a crustaceous sparry matter gathered round the surface of certain parts of the plants; both these substances are called by the common name of lapis spongiæ, the sponge-stone; and both are recommended as diuretics, and remedies against the stone and gravel. See the article SPAR.

*Pyrotechnical SPUNGES,* are made of the large fungous excrescences growing on old oaks, ashes, fir, &c. which being boiled in common water, then dried and well beaten, are put in a strong ley, prepared with salt-petre, and again dried in an oven. These make the black match, or tinder, brought from Germany, used to receive and sustain the fire struck from a flint and steel, &c.

*SPUNGE,* is also used, in gunnery, for a long staff, or rammer, with a piece of sheep or lamb-skin wound about its end, to serve for scouring great guns, when discharged, before they are charged with fresh powder.

*SPUNGE of a Horse-Shoe,* the part next the heel, where the calkins are made.

*SPUNGING,* in gunnery, the cleaning a gun's inside with a sponge, in order to prevent any sparks of fire from remaining in her, which would endanger the life of him who should load her again.

*SPUN-YARN,* among sailors, is a kind of line made from rope yarn, and used for seizing or fastening things together.

*SPUR,* a piece of metal, consisting of two branches encompassing a horseman's heel, and a rowel in form of a star, advancing out behind to prick the horse.

*SPUR-WAY,* a road through another's ground, through which one may ride by right or custom.

*SPURGE, Tithymalus,* in botany, a genus of plants, according to Tournefort, but comprehended among the euphorbias by Linnæus. See the article TITHYMALUS.

The common spurge, which grows wild in gardens, &c. is full of a milky juice, which, applied

# S Q U

to the skin, corrodes it into a scar, and is therefore used by beggars to excite compassion: it is seldom used in any medicinal forms; but the common people use it to eat off warts, which it will do, by frequent application, if the crust which hardens on them be cut off between whites.

**SPURGE-LAUREL**, in botany, a species of daphne. See the article **DAPHNE**.

This is a low evergreen shrub, which rises with several stalks from the root to the height of two or three feet, dividing upwards into several branches, which are furnished with thick spear-shaped leaves coming out irregularly on every side, and sitting pretty close to the branches, and are of a smooth and lucid green; between these, towards the upper part of the stalks, come out the flowers in small clusters of a yellowish green, in January, and are succeeded by oval berries, which are green till June, when they ripen to a black colour, and then fall off.

The whole plant is of a hot caustic taste, burning and inflaming the mouth and throat; it is but little used in medicine.

**SPURIOUS DISEASES**, such as, in some symptoms, cannot be reduced to any one kind; and therefore, are denominated from those with which they agree in most particulars: thus we say, a spurious or bastard pleurisy, quinzy, &c.

**SPURKETS**, in a ship, spaces between the upper and lower futtocks, or between the rungs fore and aft.

**SPURRY**, *Spergula*, in botany. See the article **SPERGULA**.

**SPUTUM**, among physicians, denotes the same with the saliva, or spittle. See the article **SPITTLE**.

**SPY**, a person hired to watch the actions, motions, &c. of another; particularly of what passes in a camp. When a spy is discovered, he is hanged immediately.

**SQUADRON**, in military affairs, denotes a body of horse, whose number of men is not fixed, but is usually from one to two hundred.

**SQUADRON of Ships**, a division or part of a fleet, commanded by a vice-admiral, or commodore.

**SQUAMOUS**, or **SQUAMOSE**, in anatomy, an appellation given to the spurious or false sutures of the skull, because composed of squamæ, or scales, like those of fishes, or like tiles laid so as to reach over one another.

**SQUARE**, *Quadratum*, in geometry, a quadrilateral figure, both equilateral and equiangular.

To find the area of a square, seek the length of one side; multiply this by itself, and the product is the area of the square.

**SQUARE-NUMBER**, the product of a number multiplied into itself.

Thus 4, the product of 2 multiplied by 2; or 16, the product of 4 multiplied by 4, are square numbers.

# S T A

**SQUARE-ROOT**, a number considered as the root of a second power or square number; or a number, by whose multiplication into itself, a square number is generated. See the article **EXTRACTION**.

**SQUARE-BATTLE**, or **BATTALION of Men**, is one that hath an equal number of men in rank and file.

**Hollow SQUARE**, in the military art, is a body of foot drawn up with an empty space in the middle for the colours, drums, and baggage; faced and covered by the pikes every way, to keep off horse.

**SQUARE**, *Norma*, an instrument consisting of two rulers, or branches, fastened perpendicularly at one end of their extremes, so as to form a right angle: it is of great use in the description and mensuration of right angles, and laying down perpendiculars.

**SQUASH**, in botany, a name used for a particular species of cucurbita. See **CUCURBITA**.

**SQUILL**, *Scilla*, in botany. See **SCILLA**.

**SQUIRREL**, *Sciurus*, in zoology, the English name of a genus of quadrupeds, the fore-teeth of which are prominent; it has no canine teeth; and its legs are formed both for climbing and leaping.

**STABLE**, a place or house for horses, &c. furnished with stalls and proper apartment to contain their food, &c. See the article **HORSE**, &c.

**STACK of Wood**, among husbandmen, a pile of wood three feet long, and as many broad, and twelve feet high.

**STACHYS**, base-horehound, in botany, a genus of plants whose flower is monopetalous and ringent; the tube is very short; the upper lip is erect, hooked, and often emarginated; and the lower lip is large, reflexed and trifid. There is no pericarpium; but the cup contains four ovate angular seeds.

**STADTHOLDER**, **STADTHOULDER**, or **STATHOLDER**, the principal governor or magistrate of the United Provinces.

**STÆHELINA**, in botany, a genus of plants whose flower is compound and tubulous, consisting of several hermaphrodite corollulæ, which are monopetalous, and funnel-shaped, and contained in an oblong, cylindrical, imbricated cup. The seeds are oblong, very short, and four-cornered, and crowned with a feathery down the length of the cup, and placed on a plane paleaceous receptacle.

**STAFF**, *Baculus*, an instrument ordinarily used to rest on in walking. The staff is also frequently used as a kind of natural weapon both of offence and defence, and for several other purposes.

**STAFF**, in music, five lines, on which, with the intermediate spaces, the notes of a song, or piece of music, are marked.

**STAG**, in zoology, a very stately and beautiful animal. People are apt to confound it with the common fallow deer, but with great impropriety, being

being of twice the size, and different in many other respects: the head is remarkably large: the neck strong and thick: the eyes are full and large: the ears long and patulous: the horns tall, almost erect, and of a beautiful form; they rise each with a single and elegant stem, which continues its form to the top, only sending off branches and divarications: they are hairy when once formed, but afterwards they become very strong, and lose that downy appearance. The body of the stag is rounded and plump: the back somewhat flattened, and the belly prominent; the legs are long: the hoofs cloven: the fur deep, thick, and of a tawny reddish colour.

**STAGE**, in the modern drama, the place of action and representation, included between the pit and the scenes, and answering to the proscenium, or pulpitum, of the ancients.

**STAIR-CASE**, in architecture, an ascent inclosed between walls, or a ballustrade, consisting of stairs, or steps, with landing-places and rails, serving to make a communication between the several stories of a house.

**STAKE**, the name of a small anvil, used by smiths; sometimes it stands on a broad iron-foot on the work-bench, to be moved up and down occasionally; and sometimes it hath a strong iron-spike at the bottom, by which it is fixed to some place on the work-bench. Its use is to set small and cold work straight, by hammering it on the stake; or to cut or punch upon the cold chissel or cold punch.

**STALACTITÆ**, or **STALACTAGNIA**, stony icicles, in natural history, crystalline spars formed into oblong, conical, round, or irregular bodies, composed of various crusts, and usually found hanging in form of icicles from the roofs of grottos, &c. See **SPAR**.

**STALE**, among sportsmen, a living fowl put in a place to allure and bring others where they may be taken. For want of these, a bird shot, his entrails taken out, and dried in an oven in his feathers, with a stick thrust through to keep it in a convenient posture, may serve as well as a live one.

**STALE** is also a name for the urine of cattle.

**STALK**, in botany, that part of a plant which rises immediately from the root, and which supports the leaves of the flowers and the fruit.

The term stalk is used on all occasions; but in speaking of the grasses and gramineous plants, the word culm is used in its place, to distinguish that peculiar kind of stalk, which is general to all these plants, and is not found in any others.

**STALKING**, a term used in fowling, and applied to a kind of screen, or device, to hide the fowler and amuse the game, while he gets within shot.

**STALLION**, or **STONE-HORSE**, in the manege,

an ungelt horse, designed for the covering of mares, in order to propagate the species.

**STAMINA**, among botanists, are the male organs of generation in flowers, and defined by Linnæus as an entrail of a plant designed for the preparation of the pollen or male dust. Each single stamen consists of two parts, a filament and anthera; though sometimes the filament is wanting.

By the construction, number, and distribution of the stamina, Linnæus's system of botany is principally founded and regulated thereby. Tournefort takes the use of the stamina to be as it were so many excretory canals for discharging the growing embryo of its redundant juices; and of these excrements of the fruit, he takes that farina or dust found in the antheræ to be formed: but other writers, as Geoffrey, and Linnæus in particular, assign the stamina a nobler use. These authors explain the generation of plants in a manner analogous to that of animals: they maintain the use of the stamina to be that of secreting in their fine capillary canals a juice, which, being collected, hardened, and formed into a farina, or dust, in the tips of the apices, is thence, when the flower is arrived to maturity discharged by the bursting of the apices or antheræ on the top of the pistil, whence is a passage for it to descend into the uterus or germen; where being received, it impregnates and fecundifies that part which is destined for the fruit and seeds. See **BOTANY**, **GENERATION OF PLANTS**, **FARINA**, and **PISTIL**.

**STAMINA**, in the animal body, are defined to be these simple original parts, which existed first in the embryo, or even in the seed, and by whose distinction, augmentation, and accretion, by additional juices, the animal body at its utmost bulk, is supposed to be formed. See **GENERATION**.

**STAMINEOUS**, in botany, a term used by authors, for those flowers of plants which have no petals or flower-leaves, but consist only of a number of stamina and pistils, placed in a cup. This cup is sometimes mistaken for a flower, and its leaves thought to be true petals, but they remain when the stamina are fallen, and become the capsules, containing the seed; which according to Tournefort is the true character of a cup, not of a flower.

**STAMPT-DUTIES**, certain impositions laid on all parchment and paper, on which deeds, grants, or other instruments, or any process in law or equity, are ingrossed or written.

The stamp-duties are also extended to almanacs, news-papers, pamphlets, cards and dice. All pamphlets above a sheet, and under six sheets in octavo, twelve in quarto, or twenty in folio, are subject to a stamp duty.

**STAMPS**, in metallurgy, a sort of large pestles, lifted

# S T A

lifted up by water wheels, and serving to beat to powder the ores, and the refuse of ores, of metals. This engine is called the stamping-mill, and sometimes the knocking-mill.

**STANCHION**, or **STANCHIONS**, in a ship, those pillars, which being set up pillar-wise, do support and strengthen the waste-trees.

**STAND**, in commerce, a weight, from two hundred and a half to three hundred, of pitch.

**STANDARD**, in war, a sort of banner, or flag, borne as a signal for the joining together of the several troops belonging to the same body. See **FLAG**, &c.

**STANDARD**, in commerce, the original of a weight, measure, or coin, committed to the keeping of a magistrate, or deposited in some public place, to regulate, adjust, and try the weights used by particular persons in traffic.

**STANDARDS**, or **STANDELS**, in husbandry, are young trees, reserved at the felling of woods, for the growth of timber.

**STANDING**, in the sea-language. Standing part of the sheet, is that part of it which is made fast to a ring at the ship's quarter. Standing part of a tackle, is the end of the rope where the block is fastened. Standing ropes, are those which do not run in any block, but are set taut or let slack, as occasion serves; as the sheet-stays, back-stays, or the like.

**STANNARIES**, the mines and works where tin is dug and purified, as in Cornwall, Devonshire, &c.

**STANZA**, in poetry, a certain stated number of verses, generally containing a perfect sense, that ought to end with some lively and ingenious thought, or just and pertinent reflection.

**STAPES**, in anatomy, one of the ossicula auditoria, being a lesser bone situated in the cavity of the fenestra ovalis: thus called from its resembling a stirrup. See **EAR**.

**STAPLE**, primarily signifies a public place or market, whither merchants, &c. are obliged to bring their goods to be bought by the people.

Formerly the merchants of England were obliged to carry their wool, cloth, lead, and other like staple commodities of this realm, in order to utter the same by wholesale; and these staples were appointed to be constantly kept at York, Lincoln, Newcastle upon Tyne, Norwich, Westminster, Canterbury, Chichester, Winchester, Exeter, and Bristol; in each whereof a public mart was appointed to be kept, and each of them held a court of the mayor of the staple, for deciding differences, held according to the law-merchant, in a summary way.

The staple-commodities of this kingdom are said by some to be these, viz. wool, leather, wool-fells, lead, tin, butter, cheese, cloth, &c. but others allow only the first five to be staple-commodities.

# S T A

**Staple** signifies also a city or town, where the merchants jointly agree to carry certain commodities.

**STAR**, *Stella*, in astronomy, a general name for all the heavenly bodies, which, like so many brilliant studs, are dispersed throughout the whole heavens.

The stars are distinguished, from the phenomena of their motion, &c. into fixed, and erratic or wandering stars; these last are again distinguished into the greater luminaries, viz. the sun and moon; the planets, or wandering stars, properly so called; and the comets; each whereof has been fully considered and explained under their respective articles.

As to the fixed stars, or simply stars, they are so called because they seem to be fixed, or perfectly at rest, and consequently appear always at the same distance from each other.

*Distribution and Number of the fixed STARS.*

An observer will first divide these stars into several classes, according to the splendor of their light; the brightest he will call stars of the first magnitude; those of the next inferior light, he will call stars of the second magnitude; and so in order to those that can barely be seen by the naked eye, which are called stars of the sixth magnitude: and those which cannot be seen but by the help of magnifying glasses, are of the seventh, eighth, &c. magnitudes. Afterwards, to avoid confusion, and to be able to point out any one star, without being obliged to give a particular name to each, he will divide them into separate parcels, of which he will make a particular plan; and to each of these constellations, or parcels of stars, he will assign a figure at pleasure, as that of a ram, a bull, a dragon, a Hercules, &c. but so that all the stars in each of the parcels, drawn in the plan, may be inclosed in the designed figures, and correspond to the different parts from whence they take their name: for example, having drawn the figure of a bull about a parcel, or constellation, of stars, that star which falls in the eye, will be called the star in the bull's eye, or simply, the bull's eye; another, which respects the tip of one horn, will be named the bull's horn; and so of others. A parcel of stars thus contained in any assigned figure, is called a constellation. See **CONSTELLATION**.

By this means, notwithstanding the seeming impossibility of numbering the fixed stars, their relative situations one to another have been so carefully observed by astronomers, that they have not only been able to number them, but even to distinguish the place of each star in the heavens, and that with greater accuracy than any geographer could ever point out the situations of the several cities or towns upon the surface of the earth; and not only the places of those few, if they may be so called, which are to be seen with the naked eye, have been pointed out and registered by them,

but

but even of those which are discovered only by the telescope. The most antient observations of the stars, which have reached these times, were made by Timocharis and Arristillus, about 300 years before Christ. The next after them, who made a catalogue of the stars visible to the naked eye, and registered their places, was Hipparchus of Rhodes; he flourished about 120 years before Christ, and numbered 1022 stars. After him Ptolemy enlarged his catalogue to 1026; Ulug Beigh, the grand-father of Tamerlane the Great, about the year 1437, constructed a new catalogue, more exact than that of Ptolemy, containing 1017 stars: Tycho, in the year 1600, determined the places of 777 fixed stars, and reduced them to a catalogue: Kepler's catalogue contained 1163 stars; and that of the prince of Hesse, 400: Ricciolus enlarged Kepler's catalogue to 1468; and John Bayer, a German, had described the places of 1725 stars: after this, about 1670, Hevelius of Dantzick, composed a catalogue of 1888 fixed stars: Dr. Halley also undertook a voyage to the island of St. Helena, in order to take the position of the stars within the antarctic circle, of which he published a catalogue, containing 373 stars: but the largest and most complete catalogue ever yet published, is that of our accurate astronomer Mr. Flamsteed, in his *Celestial History*, which contains near 3000 stars; all whose places are more exactly determined in the heavens, than the position of cities and other places on the earth.

We ought not however to imagine, that all the fixed stars are thus numbered, and reduced to their respective places in the heavens; since their number continually increases, according to the goodness of the telescope, appearing millions beyond millions, till, by their immense distance, they evade the sight, even though assisted by the best instruments. The telescopic stars with which Mr. Flamsteed has enriched his catalogue, are only the more remarkable ones, whose longitudes and latitudes, or situations in the heavens, it was thought worth while to register and put down. Dr. Hook, with a telescope of twelve feet, saw 78 stars among the pleiades; and with a longer telescope, still more: and, in the single constellation of Orion, which, in Mr. Flamsteed's catalogue, has but 80 stars, there have been seen 2000. We may therefore, venture to pronounce the number of fixed stars, including the telescopic ones, as well as those visible to the naked eye, to be infinitely great, far beyond what it is possible for the best astronomers to calculate, much less to reduce to order. But though the stars are certainly innumerable, yet those visible to the naked eye, in one hemisphere, seldom exceed a thousand; which, perhaps, may appear strange, since, at first sight their number seems immensely great; but this is only a deception of sight, arising from a confused and transient view; for let a person

single out a small portion of the heavens, and after some attention to the situation of the more remarkable stars therein, begin to count, he will soon be surprised to find how few there are therein. However, even the number of stars visible to the naked eye, small as it is in comparison with that of the telescopic ones, is far from being constant; since, besides that the different states of the atmosphere renders many of the lesser stars invisible, some stars have been observed to appear and disappear by turns; particularly one in the chair Cassiopeia, in the year 1572; which, for some time, outshone the biggest of the fixed stars, and in sixteen months time, by degrees, vanished quite away, and was never seen since. In the year 1640, the scholars of Kepler saw a star in the right leg of Serpentarius, which, likewise, gradually disappeared. Fabricius, in the year 1596, gives the first account of the *stella mira*, or wonderful star, in the neck of the whale; which has been since found to appear and disappear periodically, its period being seven revolutions in six years, but is never quite extinguished. Several other new stars have been observed; as one by Hevelius in 1670; and another by Mr. Kirch, in 1689. These new stars are generally observed in the galaxy, or milky-way.

As to the causes of this appearing and disappearing of the fixed stars, Sir Isaac Newton conjectures, that as it is possible our sun may sometimes receive an addition of fuel by the falling of a comet into it; so the sudden appearance of some stars, which formerly were not visible to us, may be owing to the falling of a comet upon them, and occasioning an uncommon blaze and splendor for some time: but that such as appear and disappear periodically, and increase by very slow degrees, seldom exceeding the stars of the third magnitude, may be such as, having large portions of their surfaces obscured by spots, may, by revolving round their axes, like the sun, expose their lighter and darker parts to us successively.

*Nature and Distance of the fixed STARS.* From the similitude there appears to be between them and the sun, it is generally supposed by philosophers, that they are not placed in the heavens by way of ornament only, or to supply us with a faint light in the absence of the moon; but that each of them is placed in the midst of a system of planetary worlds, and that it directs their motions, and supplies them with light and heat, in the same manner that the sun does the several bodies of which our solar system is composed; in short, that they are so many suns, which no doubt, have planets moving regularly round them, though invisible to us.

That this is not mere hypothesis, will appear from the following arguments, drawn from the analogy they bear to our sun: the sun shines by its own native light, and so do the fixed stars: the sun, at the

distance of the fixed stars, would appear no larger than a star; none of our planets, at that distance, could be seen at all: is it not probable, therefore, that each of the fixed stars is a fixed sun, surrounded by a system of planets and comets, which may be again furnished with different numbers of satellites, or moons, though invisible to us.

Besides, as the number of stars is immensely great, dispersed through spaces of the universe, far beyond the reach of the best telescopes, and as God has made nothing in vain, it seems highly probable, that they severally serve the purposes of light and heat for the planets of their systems; since nothing can be more absurd, than to pretend, that myriads of unseen stars were made to twinkle in the unknown regions of the universe.

That the fixed stars shine by their own light, is thus proved: when viewed through a telescope, they appear only as mere lucid points, destitute of all sensible magnitude, and consequently must be at a vast distance; because the satellites of Jupiter and Saturn, when viewed through a telescope, appear of very distinguishable magnitudes, and yet are invisible to the naked eye.

Since, then, the fixed stars are at such a vast distance, that the best telescope has no power to magnify them, and nevertheless shine with a very bright and sparkling light, it is inferred that they must shine with their own proper and unborrowed light; because, if their light was only borrowed, they would, like the satellites already mentioned, be invisible to the naked eye.

The celebrated Huygens found the brightest and largest, and consequently the nearest of the fixed stars (viz. Sirius, or the dog-star) to be in appearance 27664 times less than the sun; and since the distances of objects are greater, as their apparent magnitudes are lesser, the dog-star must be distant from our earth 200000000000, or above two millions of millions of English miles; which is so very great, that a cannon-ball, continuing in the same velocity it acquires when immediately discharged at the mouth of the cannon, would spend almost seven hundred thousand years in passing through it: and it is very probable, that the fixed stars are equally distant from each other, as the nearest of them is from our sun; since, the better the telescopes we make use of, the more stars are seen.

Hence, it is very natural to conclude, that all the fixed stars are not placed at equal distances from us; but that they are every where interspersed, at great distances beyond one another, throughout the universe; and that, probably, the different appearances which they make, in point of splendor and magnitude, may be rather owing to their various distances from us, than to any real difference in their magnitudes.

From what has been said, concerning the number, nature, and distance, of the fixed stars, the

hypothesis of a plurality of worlds, wherein each fixed star serves as a sun to a system of planets, seems rational, worthy a philosopher, and greatly displays the wisdom, and redounds to the glory, of the great Creator and Governor of the universe.

*Apparent Motions of the fixed STARS.* See the article ABERRATION.

*Falling-STARS, Stellæ Cadentes,* in meteorology, fiery meteors, which dart through the sky, in form of a star; being occasioned by a nitro-sulphureous matter, the common cause of all such meteors. See AURORA BOREALIS.

STAR, in heraldry, a charge frequently borne on the shield, and the honourable ordinaries, in figure of a star; which differs only from the mullet, in not being pierced as this last is.

STAR, is also a badge of honour, worn by the knights of the garter, bath, and thistle. See the article GARTER.

STAR, in pyrotechny, a composition of combustible matters, which being thrown aloft in the air, exhibits the appearance of a real star.

STAR of *Bethlehem, Ornithogalum,* in botany. See the article ORNITHOGALUM.

STAR-APPLE, *Chrysophyllum,* in botany. See the article CHRYSOPHYLLUM.

STAR-BOARD, in the sea-language, denotes the right-hand side of a ship: thus they say, star-board the helm, or helm a star-board, when he that commands would have the men at the helm, or steering-wheel, put the helm to the right side of the ship.

STAR-FORT, or REDOUBT, in fortification. See FORT and REDOUBT.

STAR-HYACINTH, *Scilla,* in botany. See the article SCILLA.

STAR-SHOT, a gelatinous substance frequently found in fields, and supposed by the vulgar, to have been produced by the meteor, called a falling-star: but, in reality, is the half-digested food of herons, sea-mews, and the like birds; for these birds, when shot, have been found, when dying, to disgorge a substance of the same kind.

STAR-THISTLE, the English name of a species of centauria, called by some, calcitrapa. See the article CENTAURIA.

STAR-WORT, *Aster,* in botany. See the article ASTER.

STARCH, a fecula, or sediment, found at the bottom of vessels wherein wheat has been steeped in water, of which fecula, after separating the bran from it, by passing it through sieves, they form a kind of loaves, which being dried in the sun or an oven, is afterwards cut in little pieces and so sold.

The best starch is white, soft, and friable, and easily broken into powder. Such as require fine starch, do not content themselves, like the starchmen, with refuse wheat, but use the finest grain.

The process is as follows: The grain, being well cleaned, is put to ferment in vessels full of water,

water, which they expose to the sun while in its greatest heat, changing the water twice each day, for the space of eight or twelve days, according to the season. When the grain bursts easily under the finger, they judge it sufficiently fermented. The fermentation perfected, and the grain thus softened, it is put, handful by handful, into a canvas bag, to separate the flour from the husks, which is done by rubbing and beating it on a plank laid across the mouth of an empty vessel that is to receive the flour.

As the vessels are filled with this liquid flour, there is seen swimming at top, reddish water, which is to be carefully skimmed off from time to time, and clean water is to be put in its place, which, after stirring the whole together, is also to be strained through a cloth or sieve, and what is left behind put into the vessel with new water, and exposed to the sun for some time.

As the sediment thickens at the bottom, they drain off the water four or five times, by inclining the vessel, but without passing it through the sieve. What remains at bottom is the starch, which they cut in pieces to get out, and leave it to dry in the sun. When dry, it is laid up for use.

To use starch, they take as much as is needed, and steep it in water over night, changing the water four or five times.

The starchmen using the refuse of wheat, only observe a part of these things in their process, but their starch falls far short of this. Starch is used along with smalt, or stone-blue, to stiffen and clear linen; the powder thereof is also used to whiten and powder the hair. It is also used by the dyers to dispose their stuffs to take colours the better.

**STARLING**, *Sternus*, in ornithology, a distinct genus of birds, of which there is only one known species, viz. the common starling, much about the size of the black-bird, only that it stands more erect, and the body is slenderer.

Its general colour is black, variegated with grey spots, and the tips of the feathers of the neck and back are yellowish: the principal feathers of the wings and tail are brown, and have some yellow at their edges.

The starling is frequent with us, and may be taught to imitate the human voice.

**STARTING**, in the manege. A horse is said to be starting, skittish, or timorous, that takes every object he sees to be otherwise than it is; whence he frequently stops, flies out, and starts suddenly to one side, inasmuch that the rider cannot make him go forwards.

This fault is more common to geldings than stone-horses, and these are most subject to it who have bad eyes, as well as those that have been kept long in a stable without airing: but these last are easily cured of it. You should not beat a starting horse

in his consternation, but get him to advance gently, and by fair means, to the object that alarms him.

**STATERA ROMANA**, or steel-yard, a name given to the Roman balance. See the article **BALANCE**.

**STATICE**, thrift, in botany, a genus of plants, whose flowers are collected in a head; the cup is scaly, and the corolla is funnel-shaped, consisting of five petals, which are narrow at their bottoms, and broad, patent, and obtuse at their tops: the stamina are five subulated filaments, inserted in the unguis of the corolla, and terminated with incumbent antheræ: there is no pericarpium; but the cup, which is constricted about the neck, and its limb expanded, contains the seeds, which are single, very small, and roundish.

The common thrift is propagated by parting its roots in autumn: it is often used for edgings in flower-gardens; but as it will not stand well above two years without replanting, and there being divers other plants more proper for that purpose, it is by many rejected.

This genus includes the limonium of Tournefort.

**STATICS**, that branch of mathematics which considers the motion of bodies arising from gravity.

Statics then is the doctrine, or theory, of motion, considered merely as arising from the weight of bodies; in which sense it is distinguished from mechanics, which is the application of statics to machines, engines, &c. though it must be owned, that statics and mechanics are frequently confounded. See the articles **MECHANICS** and **MOTION**.

**STATICS**, *Statici*, in medicine, a kind of epileptics, or persons seized with an epileptic fit; during which, they contemplate some strong and lively idea, whereby they are distinguished from cataleptics, or persons seized with a catalepsy.

**STATION**, in geometry, surveying, &c. a place pitched upon to make an observation, take an angle, or the like.

**STATIONARY**, in astronomy, signifies the appearance of a planet, when it seems to remain immoveable on the same point of the zodiac for several days.

As the earth, whence we view the motions of the planets, is out of the center of their orbits, the planets appear to proceed irregularly; being sometimes seen to go forwards, that is, from west to east, which is called the direction; sometimes to go backwards, or from east to west, which is called the retrogradation.

Now, between these two states there must be an intermediate one, wherein the planet neither appears to go backwards nor forwards, but to stand still, and keep the same place in her orbit, which is called her station; and this will happen, when the line that joins the earth's and planet's center is constantly directed

directed to the same point in the heavens; that is, when it keeps parallel to itself. For all right-lines, drawn from any part of the earth's orbit, parallel to one another, do all point to the same star; the distance of these lines being insensible, in comparison of that of the fixed stars.

Saturn is seen stationary at the distance of somewhat more than a quadrant from the sun; Jupiter at the distance of fifty-two degrees; and Mars at a much greater distance.

Saturn is stationary eight days, Jupiter four, Mars two, Venus one and an half, and Mercury an half, though the several stations are not always equal.

**STATIONARY FEVER**, a peculiar kind of fever, adapted and owing to some general constitution of the air and seasons.

Sydenham observes, that there are certain general constitutions of years, which owe their origin neither to heat, cold, dryness, nor moisture, but rather depend upon a certain secret and inexplicable alteration in the bowels of the earth, whence the air becomes impregnated with such kinds of effluvia, as subject the human body to peculiar distempers, so long as that kind of constitution prevails, which after a certain course of years declines, and gives way to another.

Each of these general constitutions is attended with its own proper and peculiar kind of fever, which never appears in any other; and this is thence called a stationary fever.

**STATUARY**, *Statuaria*, a branch of sculpture, employed in the making of statues.

**STATUE**, *Statua*, is defined to be a piece of sculpture in full relievo, representing a human figure.

Daviler more scientifically defines statue a representation, in high relievo and insulate, of some person distinguished by his birth, merit, or great actions, placed as an ornament in a fine building, or exposed in a public place to preserve the memory of his worth. In strictness, the term statue is only applied to figures on foot, the word being formed from *statura*, the size of the body.

Statues are formed with the chissel, of several matters, as stone, marble, plaster, &c. They are also cast of various kinds of metal, particularly gold, silver, brass, and lead. For the method of casting statues, see **FOUNDRY** of *Statues*.

Statues are usually distinguished into four general kinds: the first are those less than the life, of which kind we have several statues of great men, of kings, and of gods themselves; the second are those equal to the life, in which manner it was that the ancients, at the public expense, used to make statues of persons eminent for virtue, learning, or the services they had done: the third, those that exceed the life, among which, those which surpassed the life once

and a half, were for kings and emperors, and those double the life, for heroes: the fourth kind were those that exceeded the life twice, thrice, and even more, and were called colossuses. See **COLOSSUS**.

Every statue, resembling the person it is intended to represent, is called *statua iconica*. Statues acquire various other denominations. Thus,

1. Allegorical statue, is that which, under a human figure, or other symbol, represents something of another kind, as a part of the earth, a season, age, element, temperament, hour, &c.

2. Curule statues, are those which are represented in chariots drawn by bigæ, or quadrigæ, that is, by two or four horses; of which kind there were several in the circuses, hippodromes, &c. or in cars, as we see some, with triumphal arches, on antique medals.

3. Equestrian statue, that which represents some illustrious person on horse-back, as that famous one of Marcus Aurelius, at Rome; that of king Charles the first, at Charing-Cross; king George the second, in Leicester-square, &c.

4. Greek statue, denotes a figure that is naked and antique; it being in this manner the Greeks represented their deities, athletes of the Olympic games, and heroes: the statues of heroes were particularly called Achillean statues, by reason of the great number of figures of that prince in most of the cities of Greece.

5. Hydraulic statue, is any figure placed as an ornament of a fountain or grotto, or that does the office of a jet d'eau, a cock, spout, or the like, by any of its parts, or by any attribute it holds; the like is to be understood of any animal serving for the same use.

6. Pedestrian statue, a statue standing on foot; as that of king Charles the second, in the Royal-Exchange; and of king James the second, in the Privy-Gardens.

7. Roman statue, is an appellation given to such as are clothed, and which receive various names from their various dresses: those of emperors, with long gowns over their armour, were called, *statuæ paludatæ*: those of captains and cavaliers, with coats of arms, *thoracatæ*: those of soldiers, with cuirasses, *loricatæ*: those of senators and augurs, *trabeatæ*: those of magistrates, with long robes, *togatæ*: those of the people, with a plain tunic, *tunicatæ*: and, lastly, those of women, with long trains, *stolatæ*.

The Romans had another division of statues into divine, which were those consecrated to the gods, as Jupiter, Mars, Apollo, &c. Heroes, which were those of the demi-gods, as Hercules, &c. and Augusti, which were those of the emperors, as those two of Cæsar and Augustus, under the portico of the capitol.

In repairing a statue cast in a mould, they touch it up with a chissel, graver, or other instrument,

to finish the places which have not come well off: they also clear off the barb, and what is redundant in the joints and projectures.

**STATURE**, the size or height of a man.

**STATUTE**, *Statutum*, in its general sense, signifies a law, ordinance, decree, &c.

**STATUTE**, is also used for a short instrument in writing, termed statute-merchant, or statute-staple, which are in the nature of bonds, and called by the name statutes, on account of their being made pursuant to the forms prescribed by certain statutes, whereby it is directed, before what persons, and how they are to be made.

**STATUTE-SESSIONS**, is taken for a meeting of constables and house-keepers in some hundreds, by custom, for the debating of differences between masters and servants, the rating of servants wages, and bestowing persons in service, &c.

**STAUERS**, or **STAGGERS**, among farriers, a giddiness in a horse's head, which ends in madness.

This disease is frequently occasioned by turning out a horse to grass too soon, before well cold, where, by hanging down his head to feed, bad vapours and humours are generated, which oppressing the brain, are the proximate cause of this disease. Sometimes it comes by over exercise in hot weather, which inflames the blood, &c. and sometimes by noisome smells in the stable, excessive eating, &c. The signs of it are dimness of sight, reeling and staggering, watery eyes, &c. At length, for perfect pain, he beats his head against the wall, thrusts it into the litter, rises and lies down with fury, &c.

For the cure of this distemper there are various prescriptions, one of which is, first to bleed the horse, then to dissolve the quantity of a hazle-nut of sweet butter in a saucer full of wine; then taking some lint, or fine flax, dip it in the mixture and stop his ears with it, and stich them for twelve hours: some boil an ounce and a half of bitter-almonds, two drams of ox-gall, half a penny worth of black-hellebore made into powder, grains of castoreum, vinegar and varnish, of each five drams; which they boil and strain, and then put into his ears.

**STAVESACRE**, in botany, the English name for a species of delphinium. See the article **DELPHINIUM**.

It grows in shady places in the southern parts of Europe, and is cultivated in our gardens for the sake of its flowers, which are like those of the larkspur.

**STAY**, in the sea-language, a big strong rope, fastened to the top of one mast, and to the foot of that next before it, towards the prow, serving to keep it firm, and prevent its falling astwards or towards the poop.

All masts, top-masts, and flag-staves, have their stays, except the sprit-sail top-masts. That of the mast is called the main-stay. The main-mast, fore-mast, and those belonging to them, have also back-

stays to prevent their pitching forwards or over-board, as going on either side of her.

To stay a ship, or to bring her on the stays, is to manage her tackle and sails so that she cannot make any way forwards; which is done in order to her tacking about.

**STEADY**, a word of command, at sea, for the man at the helm to keep the ship steady in her course, and not to make angles (or yaws, as they call them) in and out.

**STEATOMA**, a kind of encysted tumour, consisting of a matter like suet or lard, soft, without pain, and without discolouring the skin.

**STEEL**, a kind of iron refined and purified by the fire with other ingredients.

Steel, of all other metals, is that susceptible of the greatest degree of hardness when well tempered, whence its great use in the making of tools and instruments of all kinds. Mr. Cramer observes, that the difference between iron and steel is, that the latter being much harder, will not yield to the hammer, but is brittle instead of being ductile, and resists the file. Malleable iron grows rigid by being simply extinguished in cold water, but it yet retains a considerable degree of ductility in the cold, and may be extended in all dimensions with the hammer. Steel, however, if heated again, and cooled by slow degrees, may be filed and extended more or less by the hammer. But there are many degrees in the hardening of steel; for if it has been extremely red hot, and then quenched in cold water in motion, it becomes greatly harder than if it had been but moderately red hot, and had been quenched in warm water. Steel is also of a darker colour than iron, and the surface of it, when broken, appears to consist of smaller granulated, or even striated, particles than the iron it was made of. Mr. Cramer further observes, that the method of making steel out of iron is either by cementation or by fusion. That by cementation may be performed in the following manner: choose some bars of pure iron, not too thick, and quite free from heterogeneous matter, the flexibility of it, both when hot and cold, being a very good sign thereof: prepare a cement of charcoal-dust, moderately pulverized, one part: or of charcoal-dust two parts, bones, horns, or hair of animals, burnt to a blackness, in a close vessel and in a gentle fire, and afterwards reduced to a powder, one part; wood-ashes, half a part: mix them together; prepare an earthen cylindrical vessel, two or three inches higher than the bars are long; put into the bottom of this vessel the cement, prepared as before directed, so that being gently pressed down it may cover the bottom of the vessel an inch and half deep; place then the bars perpendicularly, so that they may be every where about an inch from the sides of the vessel and from each other; fill the interstices with the same cement,

cement, and cover also the bars with it, so that the vessel may be quite full; next cover it with a tile, and stop the joints with thin lute: put this vessel into a furnace, and keep it moderately but equally red hot, for six or ten hours together; when this is over, take the red hot bars out and dip them in cold water, they will then be brittle, and turned to steel. See CEMENTATION.

The method of making steel by fusion is as follows: take of iron-ore, or of unmallegable iron, of the first fusion, divide it into small parcels, and put them into a bed made of charcoal-dust, in a smith's forge: let the quantity of iron be but small for the experiment; put to it, as a defensitive menstruum, some of the vitrescent scoræ of sand, or stones of the same nature; then put upon them a quantity of charcoal; light this, and admit only a gentle blast of the bellows, that the scoræ and the metal may both melt regularly: when this has been some time kept in fusion, take it out, and divide it into two parts, which make red hot, and hammer into long bars: finally, beat them red hot, and plunge them into cold water, and they will be found to be steel, so very hard as not to be fileable, and so brittle as to break asunder when struck with considerable force.

A bar of iron, when converted into steel, is not equally so converted in all its parts; the fire has always acted more strongly upon its surface than on its central parts, and it is therefore more perfect steel there than in its inner parts; but a perfection in the operation is not necessary to the steel's being good and useful, for the whole bar is often very good steel, as are also many bars made at the same time, yet all, perhaps, differently affected.

If the composition which is to convert the iron into steel be too strong, or if the fire be too violent, or the matter continued too long in it, in all these cases the steel will be over made. The way to meliorate such steel as this, must be to divest it of part of its salts and its sulphur, but particularly the latter; and M. Reaumur found, that, burying the bars of such steel in lime, or any other alkaline substance that would readily absorb the sulphurs, and placing it for a proper time in the fire, it would be in a manner decomposed again, and come out a very good and perfect steel.

By this management steel may again be converted or reduced to its primitive iron, and a body of any middle degree between steel and iron may be produced by stopping the process at different points of time, or continuing it till all the adventitious salts and sulphurs are drawn off or absorbed.

Annealing or nealing of steel, is by some used for the softening it, in order to make it work the easier, which is usually done by giving it a blood-red heat in the fire, and then taking it out and letting it cool of itself: some have pretended to secrets in annealing, by which they could bring down iron

or steel to the temper of lead: this was done by often heating the metal in melting lead, and letting it cool again out of the lead. But this method is found by Moxon to have no other effect than what it had from the former. Steel may, indeed, be made a little softer than in the common way, by covering it with coarse powder of cow-horn or hoofs; thus inclosing it in a leam, heating the whole in a wood-fire till it be red hot, and then leaving the fire to go out of itself, and the steel to cool.

STEELYARD, *Statera Romana*. See the article BALLANCE.

STEEPLE, an appendage erected generally on the western end of a church, to hold the bells. Steeples are denominated from their form, either spires or towers; the first are such as ascend continually diminishing either conically or pyramidally. The latter are mere parallelopipeds. See SPIRE and TOWER.

STEERAGE, on board a ship, that part of the ship next below the quarter-deck, before the bulkhead of the great cabin, where the steersman stands in most ships of war.

STEERING, in navigation, the directing a vessel from one place to another by means of the helm and rudder. He is held the best steersman who causes the least motion in putting the helm over to and again, and who best keeps the ship from making yaws, that is, from running in and out. There are three methods of steering, 1. By any mark on the land, so as to keep the ship even by it. 2. By the compass, which is by keeping the ship's head on such a rhumb or point of the compass, as best leads to port. 3. To steer as one is bidden or conned, which, in a great ship, is the duty of him that is taking his turn at the helm.

STEEVE, on board a ship. The seamen say the bowsprit or the beak-head of a ship steeves, when it stands too upright, or not straight enough forward.

STEGANOGRAPHY, the art of secret writing, or of writing in cyphers, known only to the persons corresponding.

STELLARA, in botany, a genus of plants, whose flower consists of a pentaphyllous cup, with five bipartite, plane, oblong, withering petals; the stamina consists of ten slender filaments, topped with roundish antheræ; the fruit is an ovate, close, unilocular capsule, opening with six valves, and contains a number of compressed roundish seeds. This genus includes the alfine of Tournefort.

STELLATE-PLANTS, among botanists, are those whose leaves are placed in the form of a star at certain joints or distances on the stalks, such are madder, clivers, &c.

STELLERA, in botany, a genus of plants, whose flower is monopetalous, funnel-shaped, and persistent; the tube is long and slender, and the limb

limb is divided into four or five ovate lobes; the filaments are eight or ten in number, and very short, and topped with oblong antheræ; there is neither pericarpium nor calyx; the seed is single, beaked, and shining.

**STEM**, in botany, that part of a plant arising immediately from the root, and which sustains the branches, leaves, flowers, and fruit. See **STALK**.

**STEM of a Ship**, that main piece of timber which comes bending from the keel below, where it is scarfed, as they call it; that is, pieced in; and rises compassing right before the forecable. This stem it is, which guides the rake of the ship, and all the but-ends of the planks are fixed into it.

**False stem**, in a ship, is that fixed before the right one, where that is made too flat for the ship to keep the wind well.

**STEMODIA**, in botany, a genus of plants, whose flower is monopetalous and irregular; the tube is the length of the cup, and the limb is erect and almost bilabiated; the upper lip is ovate and intire, and the under one is divided into three roundish equal parts; the stamina are four almost equal filaments, which are terminated with eight antheræ: the fruit is an ovate, oblong, bilocular capsule, containing a great many globose seeds.

**STEMPLES**, in mining, cross bars of wood in the shafts which are sunk to mines. In many places the way is to sink a perpendicular hole or shaft, the sides of which they strengthen from top to bottom with wood-work, to prevent the earth from falling in; the transverse pieces of wood used for this purpose, they call stemples, and by means of these the miners, in some places, descend without using any rope, catching hold of these with their hands and feet.

**STENTOROPHONIC TUBE**, a speaking-trumpet, thus called from Stentor, a person mentioned by Homer.

**STERCULIA**, in botany, a genus of plants, producing male and female flowers, which are apetalous; the male flower consists of a large coriaceous cup, divided into five lanceolated segments, with fifteen very short filaments joined in a column, and topped with ovate antheræ; the cup of the female flower is the same as the male, and the fruit is depressed and orbiculated, containing a great number of oval kernels.

**STEREOGRAPHIC PROJECTION**, is the projection of the circles of the sphere on the plane of some one great circle, the eye being placed in the pole of that circle. The method and practice of this projection in all the principal places, viz. on the planes of the meridian, equinoctial, and horizon, have already been given under the articles **MAP** and **PROJECTION**.

**STEREOGRAPHY**, the art of drawing the forms and figures of the solids upon a plane.

**STEREOMETRY**, *σεπεδομετρία*, that part of geometry which teaches how to measure solid bodies, i. e. to find the solidity or solid content of bodies, as globes, cylinders, cubes, vessels, ships, &c.

**STEREOTOMY**, the art or act of cutting solids, or making sections thereof, as walls or other members in the profiles of architecture.

**STERILITY**, the quality of a thing that is barren, in opposition to fertility.

**STERLING**, a term frequent in British commerce. A pound, shilling, or penny sterling, signifies as much as a pound, shilling, or penny, of lawful money of Great-Britain, as settled by authority.

**STERN of a Ship**, usually denotes all the hindmost part of her, but properly it is only the outmost part abaft.

**STERN-FAST**, denotes some fastenings of ropes, &c. behind the stern of a ship, to which a cable or hawser may be brought or fixed, in order to hold her stern to a wharf, &c.

**STERN-POST**, a great timber let into the keel at the stern of a ship, somewhat sloping, into which are fastened the after-planks; and on this post, by its pintle and gudgeons, hangs the rudder.

**STERNOHYOIDÆUS**, in anatomy, a long, thin, flat muscle, fixed by its lower extremity in the superior and lateral part of the inner or posterior side of the sternum, in the posterior part of the sternal extremity of the clavicle, in the transverse ligament which connects these two bones, and in the inner or backside of the cartilage of the first rib; from hence it runs up to the foreside of the aspera arteria, joins its fellow by a membrane which forms a sort of linea alba, and is inserted laterally in the lower edge of the basis of the os hyoides.

**STERNUM**, in anatomy, the breast-bone, being a cartilaginous sort of bone which composes the forepart of the breast, and into which the ribs are fitted.

In adults this bone is often single, but sometimes it has two, sometimes three, pieces concurring to form it. Its substance is fungous and spongy; its upper part is called the manubrium or handle, and in this there is on each side a cavity for the articulation of the clavicles. In the middle it is narrow, and broad at the lower part. To this also there adheres a cartilage, called from its figure cartilago ensiformis, or xiphoides. This is usually single; sometimes it is bifurcated, and not unfrequently bony throughout; and on each side of the sternum there are seven cavities for the articulation of the seven true ribs.

**STERNUTATION**. See **SNEEZING**.

**STERNUTATIVE**, or **STERNUTATORY**, a medicine proper to produce sneezing.

Sternutatives are of two kinds, gentle and violent. Of the first kind are betony, sage, marjorum, tobacco,

bacco, and the whole fashionable tribe of snuffs. Of the latter kind are euphorbium, white hellebore, pellitory, &c. Sternutatives operate by their sharp pungent parts, vellicating the inner membrane of the nose, which is exceeding sensible, and occasioning the serous matter contained in the glands of the nose and in several sinuses situated in the base of the cranium and the os frontis, to be expelled.

STEW, a small kind of fish-pond, the peculiar office of which is to maintain fish, and keep them in readiness for the daily use of a family, &c. The fish bred in the large ponds, are drawn out and put in here. For two large ponds of three or four acres a-piece, it is adviseable to have four stews, each two rods wide, and three long. The stews are usually in gardens, or at least near the house, to be more handy, and the better looked to. The method of making them is to carry the bottom in a continued decline from one end, with a mouth to favour the drawing with a net. See the article FISH-POND.

STEWs, or STUES, were also places anciently permitted in England to women of professed incontinency, for the proffer of their bodies to all comers. These were under particular rules and laws of discipline, appointed by the lord of the manor.

STEWARD, an officer appointed in another's stead or place, and always taken for a principal officer within his jurisdiction. Of these there are various kinds. The greatest officer under the crown is the lord high steward of England, an office that was anciently the inheritance of the earls of Leicester, till forfeited by Simon de Mountfort, to king Henry III. But the power of this officer is so very great, that it has not been judged safe to trust it any longer in the hands of a subject, excepting only *pro hac vice*, occasionally: as to officiate at a coronation, at the arraignment of a nobleman for high-treason, or the like. During his office, the steward bears a white staff in his hand, and the trial, &c. ended, he breaks the staff, and with it his commission expires. There is likewise a lord steward of the king's household, who is the chief officer of the king's court, has the care of the king's house, and authority over all the officers and servants of the household, except such as belong to the chapel, chamber, and stable. See the article HOUSEHOLD.

There is also a steward of the Marshalsea, who has judicial authority. And in most corporations, and all houses of quality in the kingdom, there is an officer of the name and authority of a steward. The steward of a ship is he who receives all the victuals from the purser, and is to see it well stowed in the hold; all things of that nature belonging to the ship's use are in his custody; he looks after the bread, and distributes out the several messes of victuals in the ship; he hath an apartment for himself in the hold, which is called the steward's room.

STEWARTIA, in botany, a genus of plants, whose flower consists of five large oval patent petals, with a great number of slender filaments, joining towards their base in a cylindric form, and terminated with roundish incumbent antheræ; the fruit is a dry apple, having five lobes and five cells, which contain in each an ovate compressed seed.

STIGMA, in botany, the extreme part of the pistillum, or female organ of generation in flowers; it is generally covered with a moisture for breaking the farina or male dust, which it dissolves, and is supposed to discharge a sufficient quantity of it to impregnate the germen below. See the articles BOTANY, GENERATION, PISTILLUM, &c.

STIGMATA, in natural history, the apertures in different parts of the bodies of insects, communicating with the tracheæ, or air-vessels, and serving for the office of respiration.

Nature has given to these minute animals a much larger number of tracheæ and bronchia than to us; all the two-winged and four-winged flies, which have a single or undivided corcelet, to which their legs are all fixed, have also four stigmata in that corcelet, two on each side; they have them also on the rings of their body, but those on the corcelet are the most considerable. Of the four on the corcelet, the two anterior ones are usually the largest; these, as well as the posterior ones, are oblong, and placed obliquely to the length of the body.

The colour of the stigmata frequently differs from that of the corcelet; some are yellowish, others of a coffee-colour, or some degrees of a fallow-colour, in flies whose corcelet is brown, black, or blue.

Flies have, beside these, several stigmata also in the rings of their bodies, perhaps in every one of them: these stigmata are not like those of the corcelet, but are round, usually a little eminent above the rest of the surface, and resembling a pin's head.

STIL DE GRAIN, in the colour-trade, the name of a composition used for painting in oil or water, and is made by a decoction of the lycium or avignon-berry in alum-water, which is mixed with witing into a paste, and formed into twisted sticks.

It ought to be chosen of a fine gold-yellow, very fine, tender, and friable, and free from dirt.

STILE, *Stilus*. See the article STYLE.

STILLATITIOUS OILs, such as are produced by distillation, in opposition to those got by infusion, expression, &c.

STILL-BOTTOMS, in the distillery, a name given by the traders to what remains in the still after the working the wash into low wines.

These bottoms are procured in the greatest quantity from the malt-wash, and are of so much value to the distiller, in the fattening of hogs, &c. that he often finds them one of the most valuable articles of the business. They might also, as Dr. Shaw observes,

observes, be put to other uses, such as the affording a large proportion of acid spirit, an oil, a fuel, and a fixed salt, and with some address and good management, a vinegar and tartar. Another advantageous use of them, is the adding them to the next brewing of the malt for more spirit: the increase of the produce from this is more than is easily conceived. It also more readily disposes the new wash to ferment, and gives the spirit a vinosity, that it cannot have without it; the proportion in this case must never exceed that of a fifth or sixth part of the whole quantity of liquor employed.

**STILL-HOUSE.** The Dutch have much the advantage of us in the structure of their still houses. The general rules in building those houses, according to Shaw, should be such as follow:

The first caution, is, to lay the floor, aslope, not flat, where any wet work is to be performed. It should also be well flagged, with broad stones, so that no wet be detained in the crevices, but all may run off, and be let out at the drains made at the bottom and sides. The stills should be placed abreast on that side of the still-house to which the floor has its current. Fronting the stills, and adjoining to the back of the wall, should be a stage for holding the fermenting backs, and these being placed at a proper height, may empty themselves by means of a cock and a canal into the stills, which are thus charged with very little trouble. Near this set of fermenting backs should be placed a pump or two, that may readily supply them with water, by means of a trunk, or canal, leading to each back; under the pavement adjoining to the stills, should be a kind of cellar, wherein to lodge the receivers, each of which should be furnished with its pump, to raise the low wines into the still for rectification; and through this cellar the refuse wash, or still-bottoms, should be discharged by means of a hose, or other contrivance.

**STIMULATING,** *Stimulus*, a property in angular or sharp bodies, whereby they vellicate and cause vibrations and inflections of the fibres of the nerves, and a greater derivation of nervous fluid into the parts affected.

Stimulants produce pain, heat, redness, &c. They may be reduced to violent penetrating depilatories, gentle sinapisms, vesicatories, and caustics. See **SINAPISM**, **VESICATORY**, &c.

**STING,** *Auleus*, an apparatus in the body of certain insects, in form of a little spear, serving them as a weapon of offence. The sting of a bee or wasp, is a curious piece of mechanism, it consists of a hollow tube, at the root of which there is a bag full of sharp, penetrating juice, which in stinging, is injected into the flesh, through the tube: within the tube, Mr. Durham has observed, there lie two sharp small bearded spears: in the sting of a wasp, he told eight beards on the side of each spear, somewhat like the beards of fish-hooks. One of these

spears in the sting, or sheath, lies with its point a little before the other, to be ready, as should seem, to be first darted into the flesh, which once fixed by means of its foremost beard, the other then strikes too, and so they alternately pierce deeper and deeper, their beards taking more and more hold in the flesh; after which the sheath or sting follows to convey the poison into the wound, which that it may pierce the better, is drawn into a point with a small slit below that point for the two spears to come out at. By means of these beards it is, that the animal is forced to leave its sting behind it, when disturbed, because it can have no time to withdraw the spears into the scabbard.

**STINK,** or **STENCH**, a disagreeable smell exhaling from a corrupted, or other body, and which is prejudicial to the nose and brain.

**STIPA**, in botany, a genus of frumentaceous plants; the flower is a bivalvular glume; the top of the outer valve is terminated with a very long arista or awn; the stamina are three capillary filaments, topped with linear antheræ; the seed is single, oblong, and closed in the chaff.

**STIPEND,** *Stipendium*, among the Romans, signified the same with tribute; and hence stipendiarii were the same with tributarii.

**STIPULATION**, in the civil law, the act of stipulating, that is, of treating and concluding terms and conditions to be inserted in a contract.

**STIRRUP**, or **STIRROP**, in the manege, a rest, or support for the horseman's foot, serving to keep him firm in his seat, and to enable him to mount.

**STIRRUP of a Ship**, a piece of timber put upon a ship's keel, when some of her keel happens to be beaten off, and they cannot come conveniently to put or fit in a new piece; then they patch in a piece of timber, and bind it on with an iron, which goes under the ship's keel, and comes up on each side of the ship, where it is nailed strongly with spikes, and this they call a stirrup.

**STOAKED**, on board a ship. When the water in the bottom cannot come to the well of the pump, they say, the ship is a-stoak, or stoaked: so they say also, the limber-holes are stoaked, when the water cannot pass through them; and the pump is stoaked, when something is got into it, which choaks it up, so that it will not work.

**STOCK**, in gardening, the stem or trunk of a tree: it is also a term used for those young plants which are intended to be grafted or inoculated.

**STOCK-GILLIFLOWERS**, *Cheiranthus*, in botany; of these there are several very beautiful species raised in gardens, and known by the names of the ten-weeks stock, the queen-stock, the Brampton-stock, and the white stock; of the former there are four varieties, producing white, red, purple, and striped flowers, with several other sorts; those with double flowers are held most in esteem, tho' the single flowered stocks must be noticed, for it is

from

from them the seeds are produced by which the double ones are obtained. The single flowers of all the sorts are tetrapetalous and cruciform, and the fruit is a long compressed pod, with two cells, which contain a number of compressed seeds, having membranaceous margins. The ten-weeks stock seed should be sown in February for the first crop, but will require a little heat to forward them, and in April the plants may be removed to where they are intended to remain; the second crop should be sown in the latter end of March, in the places where they are designed to blow: this sort flowers the same year. The queen-stock produces its flowers in May and June the second year after sowing; this sort should be sown in March, and afterwards transplanted into beds, at about six or seven inches asunder, and in August may be removed to where they are intended to flower. The Brumpton-stock is an exceeding fine flower when blown in perfection, but is very apt to be destroyed in severe winters, unless properly protected. The season for sowing this sort is in April, though it may not be amiss to sow some of the seed in March. The white and purple stocks may be managed in the same manner as the queen-stock.

The best method to obtain double flowers from any of the sorts is, not to sow the seed until it is two years old, or, if it will vegetate at three years, there will be the greater chance.

To the stocks, botanists join the wall-flower, which are called by one general name, cheiranthus. See CHEIRANTHUS and WALL-FLOWER.

*Dwarf-Stock*, *Hesperis*, in botany. See HESPERIS.

**STOCK-JOBBER**, the art or mystery of trafficking in the public stocks or funds. If stock-jobbers make any contract for the sale of stock, when they are not actually possessed of, or intitled to the same, those contracts will be deemed void. Likewise the parties so agreeing to sell, are liable to a penalty of 500 l. The time of tendering stock sold, is held to be the last hour of the day on which it was to be transferred, and then an actual transfer is not necessary, unless the person to whom it ought to be made be at the place and time ready to receive the same.

**STOCK-FISH**, or **STOCK FISCH**, in commerce, a kind of dried salted-fish, of a greyish ash-colour, and the belly somewhat whiter, being only cod-fish cured in a particular manner, which makes it necessary to beat it with sticks before it is fit for dressing.

**STOCKING**, that part of the cloathing of the leg and foot which immediately covers their nudity, and screens them from the cold, &c. Anciently, the only stockings in use were made of cloth, or of milled stuffs sewed together; but since the invention of knitting and weaving stockings of silk, wool, cotton, thread, &c. the use of cloth stock-

ings is quite out of doors. The modern stockings, whether woven or knit, are a kind of plexuses, formed of an infinite number of little knots called stitches, loops, or meshes, intermingled in one another.

Knit stockings are wrought with needles made of polished iron or brass wire, which interweave the threads, and form the meshes the stockings consists of. This operation is called knitting, the invention whereof is commonly attributed to the Scots, on this ground, that the first works of this kind came from thence. It is added, that it was on this account that the company of stocking-knitters established at Paris, in 1527, took for their patron St. Fiacre, who is said to be the son of a king of Scotland. Woven stockings are ordinarily very fine; they are manufactured on a frame, or machine of polished iron, the structure and apparatus whereof is exceedingly ingenious.

The English and French have greatly contested the honour of the invention of the stocking-loom; but we are assured, whatever pretensions the French claim to this invention, that the same was certainly devised by William Lee, of St. John's college, Cambridge, in the year 1589, though it is true, that he first made it public in France, after despairing of success in his own country.

**STOCKS**, among ship-carpenters, a frame of timber, and great posts made ashore, to build pin-naces, ketches, boats, and such small craft, and sometimes small frigates. Hence we say, a ship is on the stocks, when she is building.

**STOCKS**, *Cippus*, a wooden machine to put the legs of offenders in, for the securing of disorderly persons, and by the way of punishment in divers cases, ordained by statute, &c.

**STOEBE**, in botany, a genus of plants, whose flower is composed of a number of monopetalous hermaphrodite corollulae, which are divided into five segments at the limb, and contained in one common, roundish, imbricated cup; there is no pericarpium, but the seeds, which are oblong and crowned with a long feathery down, are contained in the cup.

**STOECHAS**, in botany, Tournefort's name for a kind of Lavender, now comprehended by Linnaeus among the lavenders. See the article LAVANDULA.

**STOICS**, a sect of ancient philosophers, the followers of Zeno, thus called from the Greek *στοα*, which signifies a porch or portico, in regard Zeno used to teach under a portico, or piazza. It was the common fault of the Stoics to introduce abundance of subtilty and dryness into their disputations, either by word of mouth, or in writing. They seemed as carefully to avoid all beauty of style, as depravity of morals. Chrysippus, who was one of the Stoics, did no great honour to his sect, and could only disgrace it. He believed the gods perishable,

able, and maintained, that they would actually perish in the general conflagration. He allowed the most notorious and most abominable incests, and admitted the community of wives among sages.

To the praise of the stoics, in general, it must, however, be confessed, that, less intent than other philosophers upon frivolous and often dangerous speculations, they devoted their studies to the clearing up of those great principles of morality which are the firmest supports of society; but the dryness and stiffness that prevailed in their writings, as well as in their manners, disgusted most of their readers, and abundantly lessened their utility.

Zeno's chief followers, among the Greeks, were Lucippus, Cleanthus, Chrysippus, Diogenes Babylonius, Antipater, Panætius, Possidonius, and Epictetus. Among the Romans, Cato, Varro, Cicero, Seneca, the emperor Antoninus, &c.

The Stoics cultivated logic, physics, metaphysics, &c. but especially ethics. The principal of their dogmata, of the former kinds, are, that there are certain catalepsias, or comprehensions, called also *καὶ εἰσβολαί*, innate ideas, or principles naturally found in the mind: that God is the seminal cause of the universe, and with the Platonists, that the world is an animal, by reason of God's inhabiting and informing every part thereof: that nature is an artificial fire, tending to generation: and that the world is at last to be destroyed by a conflagration.

As for the morality of the Stoics, it was couched much in paradoxes; as, that a wise man is void of all passions, or perturbation of mind; that pain is no real evil, but that a wise man is always happy in the midst of torture, is always the same, and is always joyful; that there is none else free; that none else ought to be esteemed king, magistrate, poet, or philosopher; that all wise men are great men; that they are the only friends or lovers; that nothing can happen to them beyond their expectations; that all virtues are insensibly connected together; that all good things are equal, and equally to be desired; that goodness admits of no increase or diminution.

They own but one God, whom they, however, call by various names, as Fate, Jupiter, &c. by which they did not mean various things, but various powers and relations of the same thing. Providence they expressed under the name Fate, which Chrysippus defines to be a natural series, or composition of things mutually following each other, by an immutable nexus, or tie, fixed from all eternity. They held the immortality of the soul.

STOLE, *Stola*, a sacerdotal ornament worn by the Romish parish-priests over their surplice, as a mark of superiority in their respective churches; and by other priests, over the alb, at celebrating of mass, in which case it goes across the stomach; and by deacons, over the left shoulder, scarf-wise; when the priest reads the gospel for any one, he lays the

bottom of his stole on his head. The stole is a broad swath, or slip of stuff hanging from the neck to the feet, with three crosses thereon. The bishops anciently pretended, that the parish-priests were never to appear before them, but in their stoles. In Flanders and Italy, they always preach in stoles; it is supposed to be a representation of the extremities of the long robe, worn by the high-priest of the Jews.

*Groom of the STOLE*, the eldest gentleman of his majesty's bed-chamber, whose office and honour it is to present and put on his majesty's first garment, or shirt, every morning, and to order the things in the chamber. See BED-CHAMBER.

*Order of the STOLE*, an order of knights instituted by the kings of Arragon.

Another military order, at Venice, is called the order of the golden stole; thus called from a golden stole, which those knights wore over their shoulder, reaching to the knee, both before and behind, a palm and a half broad. None are raised to this order but patricians, or noble Venetians. It is uncertain when either of these orders was instituted.

STOMACH, *στομαχος*, in anatomy, is a hollow membranous part, placed mostly in the left hypochondrium, immediately under the diaphragm, and in an oblique situation, between the liver and the spleen. Its figure, as may be seen in our figure and description of the intestines, is like that of the bag of a pair of bag-pipes. Its division is into two parts, viz. into two orifices and a bottom. Its left orifice, called cardia, is placed much higher than its right, and is continuous with the gula, and furnished with a great number of nerves. Its right orifice is called the pylorus, and is connected with, or opens into the intestines. In this part there is a singular valve, the office of which is to close the stomach. The pylorus is connected to the upper part of the stomach by a ligament. See HYPOCHONDRIA, DIAPHRAGM, &c.

The size of the stomach in human subjects is various; in people addicted to gluttony, it is usually very large; and in men it is in general larger than in women. In the human body it is always single, but many of the beasts have several stomachs. Its vessels are arteries, veins, nerves, and lymphatics. Its arteries, called gastricae, it receives from the coeliac: the gastric veins all run to the vena portae; among these are observable, the vasa brevia, which go off to the splenic branch, and the vena coronaria, which surrounds the stomach. Its nerves principally enter at the left orifice; they come from the par vagum, and are very large, and hence it is that the stomach is so sensible: the lymphatics go to the receptaculum chyli.

The substance of the stomach is membranaceous, and is composed of four coats. The first coat is membranaceous, in the strict sense of the term: the fibres of this run transversely. The second is muscular;

culous; in this the course of the fibres is various, and as it were inextricable. Some of them run circularly, as it were, from the upper part to the lower; and others, only on the upper part of the stomach, between the two orifices; others run obliquely from the left side to the right, and some surround the orifice. The third coat of the stomach is nervous; this forms a multitude of wrinkles, and is furnished with a number of sanguiferous vessels, and small glands, which secrete the liquor gastricus, or liquor of the stomach; this is more readily observed in hogs, than in the human body. The fourth is a thin, villose, and porous coat, and adheres very firmly to the former.

The use of the stomach is for the digestion of our food, that is, to receive, contain, dissolve, and change what is swallowed by the mouth; and after a sufficient concoction, to expel it through the pylorus into the intestines; possibly it also absorbs, and retains the most subtle parts of what it has thus prepared for nutrition. It also is the organ in which the sensation of hunger resides.

For the action of the stomach in turning the aliments into chyle, see **CHYLIFICATION**.

*Heart-Burn, or Pain in the Stomach.* See the article **CARDIALGIA**.

**STOMACHIC FEVER.** See the article **MESENTERIC FEVER**.

**STOMACHIC**, in pharmacy, medicines that strengthen the stomach, and promote digestion, &c. See the article **DIGESTION**.

Stomachic corroborants are such as strengthen the tone of the stomach and intestines, among which are carminatives, as the roots of galangals, red gentian, zedoary, pimpinella, calamus aromaticus, and arum. Of barks and rinds, those of canella alba, sassafras, citron, Seville and China oranges, &c. Of spices, pepper, ginger, cloves, cinnamon, cardamums, and mace.

Other things of this nature are, among simples, Roman and common chamæmile, wormwood, mint, carduus benedictus, and the four carminative seeds. Of preparations, the oil of cedar, oil of oranges by expression, oils of common chamæmile, daucus creticus, anisum stellatum, cumin, caraway, mint, and wormwood, with the spirit of salt and sweet nitre.

Among compounds, are the sal volatile sylvii, the stomachic elixir, the essence of orange-peel, with sweet spirit of nitre, tincture of tartar, oils of oranges prepared by expression, the compound essence of wormwood, &c.

**STOMACHIC**, is also applied to the arteries, veins, &c. of the stomach. See the article **STOMACH**.

**STOMATICA**, a term used by some for all medicines used in disorders of the mouth and fauces.

**STONES**, in natural history, are defined to be essentially compound fossils, not inflammable, nor soluble in water or oil, nor at all ductile; found in continued strata, or beds, of great extent; formed either of a congeries of small particles, in some degree resembling sand, and lodged in a smother cementitious matter, and the grit or sand-like particles, running together into one smooth mass; or, finally, of granules cohering by contact, without any cementitious matter among them; or composed of crystal or spar, usually debased by earth, and often mixed with tale, and other extraneous particles.

Of this class of fossils there are three orders; and under these, eight genera.

The first order comprehends all the coarse, harsh, and rough stones, of a lax texture, and composed of a visible grit, resembling sand in form, and usually immersed in a cementitious matter, and of little natural brightness; scarce capable of any polish, and naturally mouldering away in form of powder from the tools of the workmen. The genera of this order are two, viz. the amnochista and psaduria; the former of which constitute our grey and rough slates, and the latter comprehends most of the stones used in building, particularly Portland stone. See the articles **SLATE** and **PORTLAND-STONE**.

The second order consists of stones moderately fine, of a more compact and even texture, scarce distinguishable construction, and affording no sand-like particles to the view; of some natural brightness, capable of a tolerable polish, and flying off from the tools of the workmen in form of small chips. Under this order are comprehended the symplexia and stegania. See the articles **SYMPEXIA** and **STEGANIA**.

The third order consists of stones of a very fine substance and elegant structure, naturally of a great brightness, and capable of an elegant polish; composed of granules of various shapes and sizes, but usually flattish, sometimes more, sometimes less distinct; and, in some species, running together into uniform masses, but never lodged in any cementitious substance. Of this order are the marbles, alabastrs, porphyries, and granites.

**STONE**, *Lithiasis*, and *Calculus Humanus*, in medicine, a stony or terrestrial concretion in any of the urinary passages, which occasions a difficulty in making water, and a pain in the small of the back, or about the os pubis.

When this collection is so large as to form one or more bodies (unable by reason of their size to pass through the conduits of urine) they frequently cause great pain, ulcers in the parts, and an intire suppression of urine; and, from the part where this obstructing matter happens to lodge, this distemper receives its denomination, as from the kidneys, bladder, ureters, or urethra.

This

This disorder, says Dr. Shaw, may sometimes have an hereditary cause; that is, the urinary passages may be naturally straighter than they ought to be; or the constitution may be naturally disposed to generate a stony matter; an obstructed perspiration, and a cold or moist air, may also give rise to it; for by means hereof the more heavy particles of the animal fluids will be detained in the body.

Another occasion of this distemper may be the use of such waters, as by running through various strata of the earth, are impregnated with stony particles. There are some wines too, and other liquors, which being either foul or not sufficiently fined down, or abounding in tartar, or other terrestrial corpuscles, may lay the foundation for the stone. Again, in persons subject to the asthma or gout, who have a weak digestion, viscid chyle, and stony concretions in the joints, there are manifest seeds of this distemper. In short, whatever can bring on an accumulation of earthy particles in the urinary passes, whether by obstructing or lessening the capacity of the canals, or by immediately or remotely producing the substance itself, will cause gravel, and in time the stone.

The symptoms of the gravel or stone are, frequently, a nausea and vomiting, with a numbness down the leg and thigh of the party affected; a pain fixed or moveable, great or less, in proportion to the bulk of impacted matter felt generally about the region of the loins, os pubis, and parts adjacent. This pain is very acute, and almost continual, when the gravel or stone remains at the head of the ureters; but begins to lessen, as it is protruded forwards. Sometimes when the stone is angular, or continues long fixed, the urine is bloody; and, generally in nephritic obstructions, it is thin, and made in a small quantity, especially at the beginning of the fit. Sometimes there happens a total suppression of it, in which case both the ureters may be obstructed.

When the obstructed matter is forced into the bladder, the urine is turbid, and comes away plentifully; and there appears in it much sand, and sometimes small stones; which when angular, are seldom voided without much pain; and when the paroxysm is violent, and of long continuance, there sometimes happens an entire suppression of stool, so far, that cathartics lose their force; and sometimes too, though rarely, the terrestrial matter is deposited in such parts where the canals are lax and the circulation languid, so as at the same time to occasion both an arthritic and nephritic fit. When a stone is lodged in the urethra, the pain generally proves exquisite, but limited to the part, where sometimes the stone will bulge outwards, and may be felt with the fingers.

All paroxysms, in case of a confirmed stone, are dangerous. An accumulation of sand in the kidneys or ureters, is less dangerous than a formed stone.

A stone in the kidneys is of worse consequence than in the ureters, and more or less so in proportion to its bigness. The largest stone, naturally capable of passing the urethra in men, is supposed to be about the size of a small hazle-nut; but in women, one considerably larger may pass the meatus urinaris. When both kidneys, or both ureters, are affected, it is so much the more dangerous, especially if attended with sharp pain, exulceration, inflammation, want of sleep, loss of strength, a fever, suppression of urine, &c. When the symptoms continue many days without intermission, the case is desperate; especially if coldness has seized the extremities, the pulse ticks, and the patient has cold sweats, &c. When the case is habitual or hereditary, or happens in old age, or gouty constitutions, it is difficult.

The symptoms of bloody urine, continuing after the fit is gone off, prove hard to remove. When the urine is plentifully discharged, has its ordinary sediment, is turbid, and the symptoms decrease, it is a sign the paroxysm is going off. If a large stone be long detained in the urethra, especially if it be rugged, and can neither be propelled backwards nor forwards, and there be a total suppression of urine, the case usually proves mortal.

As to the method of cure, it consists in the easy exclusion of the stone, and the preventing of breeding of others. To this purpose, Sydenham recommends bleeding, a posset-drink, in which two ounces of marsh-mallow roots have been boiled, and an emollient clyster; after which he advises a pretty large dose of an opiate; that is, about twenty-five drops of the thebaic tincture, or fifteen grains of the saponaceous pills. And Huxham tells us, that nothing is so efficacious to ease the pain, and promote the descent of the stone through the ureters, as a tepid and emollient bath.

Dr. Mead assures us, that it is an error in practice, to give strong forcing diuretics, with a view of driving out the gravel with the urine: whereas this intention is answered with greater safety, in most cases, by relaxing and lubricating medicines; especially if, in case of violent pain, bleeding be premised, and anodynes interspersed. He therefore advises, to give three or four grains of opium, dissolved in five or six ounces of the common decoction, by way of clyster. However, he allows, there are conjunctures, after the pain is abated, when powerful diuretics may be administered; but with this precaution, that as soon as they have had their effect, they are no longer to be continued. All this time, the body should be kept open, by giving a turpentine clyster, and sometimes purging gently with an infusion of fenna and manna, because strong cathartics are to be avoided.

The chief lubricating medicines are oil of sweet almonds, syrup of marsh-mallows, emulsions made with almonds, and the like; to which may be added the

the use of the warm bath. Soap and lime-water are also celebrated lithontriptics.

Such as have a stone in the bladder, should, while they are taking the foresaid medicines, have four ounces or upwards of tepid oyster-shell lime-water injected into the bladder every day; taking care to evacuate their urine before injection, and to retain it as long as they can without pain. And, were it not for the trouble of introducing the catheter, the injection might be made at least twice every day; and if a flexible catheter were always kept in the bladder, it might be done at pleasure, and the dissolution of the largest stone quickly procured. The lime-water will be safer, and yet lose nothing of its virtue, if a dram of starch, or the fourth part of the yolk of an egg, be boiled in six or seven ounces of it.

Those who, though they have no stone in the bladder, are nevertheless frequently troubled with fits of the gravel in the kidneys, may probable put a stop to the disorder, by drinking every morning a pint of oyster-shell lime-water, two or three hours before breakfast. Its disagreeable taste may be mitigated, by adding a very small quantity of new milk to it: also a dram and a half, or two drams, of juniper-berries, infused in every quart bottle of it, will mend its taste much.

As to the regimen to be observed, Dr. Mead recommends a mild diet, and such as is easy of digestion; and wine and water, mead, or new soft ale, for drink; and gentle exercise, especially riding. See the articles DIET and REGIMEN.

For the several operations in cutting for the stone, or the method of cure by extraction, see the article LITHOTOMY.

STONE, also denotes a certain quantity or weight of some commodities. See the article WEIGHT.

A stone of beef, at London, is the quantity of eight pounds; in Herefordshire, twelve pounds; in the north, sixteen pounds.

A stone of wool (according to the statute of 11 Hen. VII.) is to weigh fourteen pounds; yet in some places it is more, in others less; as in Gloucestershire, fifteen pounds; in Herefordshire, twelve pounds.

A stone, among horse-courfers, is the weight of fourteen pounds.

STONE-CROP, in botany, a species of sedum. See the article SEDUM.

STONEHENGE, in antiquity, a famed pile or monument of huge stones on Salisbury plain, six miles distant from that city.

It consists of the remains of four ranks of rough stones, ranged one within another, some of them, especially in the outermost and third rank, twenty feet high, and seven broad; sustaining others laid across their heads and fastened by mortises: so that the whole must have anciently hung together.

Antiquaries are now pretty well agreed that it

was a British temple; and Dr. Langwith thinks it might easily be made probable, at least, that it was dedicated to the sun and moon. Inigo Jones has given a fine scheme of the work, and strives hard to persuade the world, that it was Roman: but Dr. Langwith, who took his measures on the spot, assures us he could by no means reconcile them with that scheme.

STONY LANDS, in agriculture, such as are full of flints, pebbles, or small fragments of free-stone.

These lands, in many places, yield good crops; and the general rule is, that, in cold and stiff lands, the stones should be carefully removed; but, in light and dry lands, it will be advantageous to leave them. However, they always fallow these lands every other year, unless they sow pease upon them; sometimes they sow them with lentils; and when they are quite worn out, they lay them down for clover, or rey-grass.

STOOL, *Alvus*, in medicine, an evacuation or discharge of the feces, &c. by the anus.

STOOMING of Wine, is the putting bags of herbs, or other ingredients, into it. See the article WINE.

STOP, in the manege, is a pause, or discontinuance of a horse's motion.

To form a stop, you must, in the first place, bring to the calves of your legs to animate him, bend your body backwards, raise the bridle-hand without moving the elbow, then vigorously extend your hams, and rest upon your stirrups; and make him form the times or motions of his stop, in fal-cading his haunches three or four times.

STOPS, or points, in grammar. See the articles POINT and PUNCTUATION.

STOPPER, in a ship, a piece of cable-laid rope, having a wale-knot at one end, with a laniard fastened to it; and the other end is spliced round a thimble in the ring-bolts upon deck, and at the bits: its use is to stop the cable, that it may not run out too fast; in order to which, they make turns with the laniard about the cable, and the wale-knot stops it, so that it cannot slip away faster than is necessary.

STORAX, or STYRAX, in natural history and pharmacy, a dry and solid resin, of a reddish colour, and a peculiarly fragrant smell, of which there are two kinds, the styrax calamita, or styrax in tears, and the styrax vulgaris, whereof the former is by far the purer and finer kind, imported in small loose granules; or else in large masses composed of such granules: it antiently used to be packed up in reeds, for the more secure carriage; whence the name. The common storax is likewise a fine and pure resin, though less so than the former; and is brought to us in large lumps, not formed of granules, but of one uniform consistence.

These

These are the two genuine kinds of storax ; but neither of them is that met with in our shops, which is a kind of saw-dust connected into lumps, by just so much of the storax-resin, as will make the other matters hang together. This is what our apothecaries use, under the name of storax ; but it is advisable, to strain carefully the pure resin from the filth, and use no part of the latter.

The two genuine kinds of storax, which ought always to be used where they can be had, differ only in this ; that the granulated storax flows naturally from the styrax-tree, and the common kind is obtained from the same tree, by incision.

Storax is brought to us from Syria, and the East-Indies ; and ought to be chosen pure, very fragrant, and of an acrid taste. It is much recommended as a detergent and balsamic, in disorders of the breast : it is also esteemed a cordial, and is recommended in vertigos, and other disorders of the head and nerves.

**Liquid STORAX**, in pharmacy, is a drug very different from the resin above described ; being a resinous juice, of the consistence of Venice-turpentine, or thicker : it is, when clean, pellucid, of a brownish colour, with a cast sometimes of reddish, and sometimes of greyish in it. Its smell is somewhat like that of common storax, only much stronger, and even disagreeable : its taste is acrid, aromatic, and somewhat bitterish ; and it is oily, or unctuous. It should be chosen thin, pellucid, of a clean brown colour, and of a very strong smell.

There is another coarser and very impure kind, not at all pellucid, and of a grey or brownish colour : its smell is much more languid, and also more disagreeable than that of the pure kind ; whereof it seems to be only the dregs, though it is by much the most common liquid storax in the shops.

Petiver gives the most rational account of the origin of liquid storax ; which, he says, is prepared from the bark of a tree, called by the Turks *rosa mallos*, which is frequent in the island Cobras. The bark of this tree being bruised and macerated in sea-water, is boiled to the consistence of bird-lime ; they then collect the resinous matter that swims on the top ; which, being foul, is boiled again in sea-water, and strained : what passes the is the finer, and what remains in them the coarser liquid storax. He adds, that liquid storax is much esteemed in the east, as a perfume. As to its medicinal virtues, they are nearly related to those of turpentine : it is prescribed, internally, as a detergent and diuretic ; and externally, to prevent mortifications. The French speak much of the virtues of the ointment called *unguentum de styrace*, which is thus prepared : melt in five ounces of nut-oil, gum elemi and yellow wax, of each three ounces and three drams ; add of colophony, seven ounces and a half : and when all these are perfectly melted

together, add three ounces and three drams of pure liquid storax ; and let the whole be well mixed, and then cool.

**STORK**, *ciconia*, in ornithology, a species of ardea, with the long wing-feathers black : its general colour is white, which with the black wing-feathers makes a very pleasing variegation : the legs are red, very long, and naked a great way up : when it stands erect, it is between three and four feet high ; and its body is about the size of a goose.

But besides the common stork, there are two other species of ardea known by the same name, viz. the black stork, with the breast and belly white, an erect and beautiful bird, somewhat larger than the common heron ; and the brasilian stork, variegated with black and white, much about the size of the common heron.

**STOVE**, in gardening, a kind of conservatory, artificially warmed for the preservation of those tender exotic plants that are natives of the torrid zone, which without such assistance are incapable of enduring the cold of this climate.

Stoves differ from green-houses by being constantly warmed by fire ; whereas green-houses are designed for less tender plants, and merely to exclude the sharpness of the external air in winter.

Of stoves there are two kinds, the dry and bark stove ; and are of various constructions, according as conveniency or fancy directs. Of the dry stove we must refer to the article green-house, it being more immediately connected with it. The stove for the ananas or pine-apple, is explained under the article hot-house : but the following is a description of a stove intended for those very curious exotics which cannot possibly exist in this country, were it not for these artificial contrivances ; such as the cashew, all-spice, banane, cabbage-tree, cocoa-nut tree, date-tree, fustic-tree, ginger, guaiacum, log-wood, manie, manchineel, mimosa, bondue, palm, plantain, sugar-cane, sugar apple, tamarind, with numbers of other plants which are natives of the East and West-Indies, Africa, &c. In Plate LXXXV. fig. 1, 2, 3, is a view of a stove of this kind, with the ground plan and section, where *d* is the fire-places ; *f* the flues ; *w* the walk. The length of this stove is forty feet ; and the breadth, exclusive of the shed, is fifteen feet five inches ; the back wall one foot two inches ; the flue one foot ; the walk two feet ; the wall of the bark-bed nine inches ; the width of the bark-bed eight feet ; the walk in front one foot six inches, and the front wall nine inches. This sort of stove may be extended to any length at pleasure, allowing a fire-place for every twenty feet, otherwise the house cannot be sufficiently warmed in severe weather. The shed at the back is absolutely necessary, not only to keep the back of the stove warm, but also to receive the plants when it should be necessary in winter to stir up the bark and refresh

refresh it with new; as also to shelter the fires from the winds. The top and front of the stove should be covered in bad weather either with tarpaulins or shutters, which will considerably add to the warmth, and save much fuel. The stove plants may be arranged according to their hardiness; those which are most susceptible of cold should be plunged in that part of the bark-bed which is nearest to the fire-place, there being the greatest heat; the other sorts which are less tender may occupy the other parts of the bed; but they all should be placed so as to form a theatrical surface; that is, the tallest plants in the back, and the shortest in front, by which disposition they will better receive the rays of the sun: see the section in the plate. In the stove there should be kept a well graduated thermometer, by which the heat may be regulated: this should be hung up in the coolest part of the house, with the back of it towards the sun, whereby the temperature of the air may be more accurately known, and the fires increased or diminished accordingly.

**STRAIGHT, STREIGHT, or STRAIT**, in hydrography. See **STRAIT**.

**STRAIN**, in surgery, a violent extension of the sinews, or tendons, of some muscle.

**STRAIT, or STREIGHT**, in hydrography, is a narrow passage out of one sea into another, as those of Gibraltar and Magellan.

**STRAKES**, in the sea-language, signify the uniform ranges of planks on the bottom, decks, and sides of ships; and the garboard-stroke is that next the keel.

**STRAMONIUM**, in botany, Tournefort's name for the datura of Linnæus. See **DATURA**.

**STRAND**, signifies any shore of the sea, or bank of a great river: hence an immunity from paying customs on goods or vessels, was antiently expressed by strand and stream.

**STRANDED**, among seamen, is said of a ship that is driven ashore by a tempest, or runs on ground through ill steerage, and so perishes.

Where any vessel is stranded, the justices of the peace are impowered to command the constables near the sea-coast to call assistance, in order to preserve the same, if possible.

**STRANGURY**, in medicine, a difficulty of making water, wherein the urine comes away drop by drop, and is attended with a spasmodic pain about the sphincter and neck of the bladder; in which sense it is distinguished from a dysury and ischury. See **DYSURY** and **ISCHURY**.

As to the treatment, in order to obtund the acrimony of the blood, and take off the spastic motions, there is no medicine so useful as nitre, whether given alone, or mixed with some absterfve salt, or with an obsorbent, mixed with a small quantity of an acid to saturate it, and with a little cinnabar. A compound powder may be prepared of these ingredients, and a scruple of it given four times a day,

will usually soon take off the complaint. The cooling emulsions, made with barley-water and almonds, and with the cold-seeds, are also of great service: and when there is farther occasion for medicines, gum arabic, and pills of boiled turpentine, are found very good ones; and decoctions of liquorice roots in barley-water, with syrup of marsh-mallows, may be drank in large draughts. Many people are also fond of external remedies, and recommend onions, roasted and buttered, to be applied to the pubes, and goat's suet to be rubbed warm about the navel.

A common strangury is often carried off by mere diluters, such as tea, barley-water, or any other watery liquor, drank in large quantities, till a sweat comes on; and in the gentler cases, where these alone are not quite effectual, there is no better addition to them than a little nitre. Bleeding in time often prevents great mischiefs from these disorders; and in cases of a dysury, brought on by the taking cantharides, there is no remedy so powerful as warm milk alone, drank in large quantities. Mr. Boyle has also said much in favour of Venice-soap on this occasion.

**STRAP**, among surgeons, a strong piece of leather, or the like, used for stretching limbs, in the setting broken or dislocated bones.

**STRAPS of a Saddle**, are strong leather thongs, nailed to the bows of a saddle, in order to make the girths, &c. fast.

**STRAP**, in a ship, is a rope spliced about any block, or made with an eye, to fasten it any where on occasion.

**STRATA**, in natural history, the several beds or layers of different matters, whereof the body of the earth is composed.

The strata include all the layers of earths, minerals, metals, stones, &c. lying under the upper tegument, or stratum, the turf or mould.

The time when the several strata were laid, was doubtless at the creation; unless, with some great naturalists, as Steno, Dr. Woodward, &c. we suppose the globe of the earth to have been dissolved by the deluge.

The most frequent opportunities we have of observing these in England, is in the coal-mines; where we find them lying in a regular manner, on what appears to us a plane, as we see any small part of it: but when we consider the same strata, according to the globular figure of the earth, and suppose the mass of the earth to consist of the foregoing, and perhaps in different parts, and at different depths, of strata of ten thousand other kinds, all originally, while in a soft and fluid state, tending toward the center, we shall find that it must mechanically and almost necessarily follow, by the continual revolution of the crude mass from west to east, like the winding up of a jack, or the rolling up of the leaves of a paper-book, that every one of these

strata,

strata, though they each reach the center, must, in some place or other, appear to the day, or on the surface. In which case there needs no specific gravitation to cause the lightest to be uppermost; and were it practicable to sink to the center of the earth, all the strata that are would be found in every part, and, according to the poet, *ponderibus liberata suis*. Add to this, that, according to an observation of Dr. Stukely, the precipices of all hills are to the westward, whereas the ascent to the east is more gradual.

**STRATAGEM**, or **STRATEGEM**, in the art of war, any device for the deceiving an surprising an enemy.

**STRATIFICATION**, in chemistry, the ranging any thing to be calcined in several layers or strata one above another; which operation is denoted by the abbreviation *s. s. f.*

**STRATOITES**, in botany, an aquatic plant growing in standing waters in several parts of England; the leaves are of a greyish colour, about a foot long, serrated on their edges, and disposed like those of the *aloe*: from the center arise two or three stalks, which are terminated by a diphyllous, compressed, obtuse spatha, from which bursts a white flower, consisting of three roundish heart-shaped petals, with many yellow stamina, and six pistils divided into two parts, which are succeeded by a hexangular capsule with six cells, containing a great many oblong-incurved seeds.

This is the same with the *aloides* of Boerhaave.

**STRAWBERRY**, *Fragaria*, in botany, a genus of plants, whose flower consists of five roundish patent petals, disposed in the form of a rose, and inserted in the cup; the stamina are twenty subulated filaments, topped with lunulated antheræ; the germina are small, numerous, and collected into a head, which afterwards becomes a well known large soft pulpy fruit, containing a great number of small angular seeds.

There are several kinds of strawberries, as the common or wood-strawberry, the white wood-strawberry, the hautboy-strawberry, the scarlet strawberry, the large Chili-strawberry, the green or pine-apple strawberry; the first and second sorts are found wild in the woods, from whence they are transplanted into gardens, by which the fruit is much improved. The best soil for these plants is a fresh loam. They are all propagated from runners, which they produce in great plenty in July, and if the weather is moist they quickly take root, which when they have sufficiently obtained, should be planted out where they are intended to fruit, taking the opportunity of moist weather; they should be planted in beds about three feet and a half wide, leaving a path for the conveniency of watering and gathering the fruit. The wood-strawberry may be planted at about six inches asunder, but the other sorts require a greater distance. When the fruit is

ripe and gone, the runners should be taken off, and the old plants cleaned of decayed leaves, and the earth stirred about them. These will not last well above three years; therefore there should be a fresh plantation made every year, in order to have the quantity required. If the weather is dry when they are in flower, it is necessary to water them on evenings, but not to wet the blossoms. In autumn, the walks between the beds should be dug up, and a little fine earth thrown on the beds, so as not to bury the plants, this will greatly strengthen them for fruiting the following year.

Strawberries do very well forced in the spring, either on hot-beds or in a stove; in the latter they should be planted in pots the preceding autumn and about Christmas, and placed in the front of the place where they can conveniently stand: the most common sorts forced are the wood and scarlet-strawberries, which, if properly managed, will produce ripe fruit in February; and by putting them in at different periods, may be continued till those in the natural ground are ripe. To have strawberries in autumn, the best method is to cut them down when in flower at the natural season, afterwards a second crop of blossoms succeed, and the fruit ripens in September and October.

Strawberry-leaves are frequently used in gargarisms for sore mouths, quinies, and ulcers of the throat.

The fruit is very grateful both to the palate and stomach, abating heat, quenching thirst, loosening the belly, promoting urine, and expelling small gravel.

**STRAY**, or **ESTRAY**, in law. See the article **ESTRAY**.

**STRENGTH**, *Vis*, in physiology, the same with force.

**STRENGTHENERS**, in pharmacy, medicines that add to the bulk and firmness of the solids: and such are all absorbent, agglutinant, and astringent medicines.

**STRIATED**, among botanists, a term applied to those leaves or fruit which have a number of longitudinal furrows on their surfaces.

**STRICTOR**, in anatomy, the same with constrictor and sphincter.

**STRIKE**, a measure of capacity, containing four bushels.

**STRIKE**, among seamen, is a word variously used; when a ship, in a fight, or on meeting with a ship of war, lets down or lowers her top-sails, at least half-mast high, they say she strikes, meaning she yields, or submits, or pays respect to the ship of war. Also, when a ship touches ground, in shoal-water, they say she strikes. And when a top-mast is to be taken down, the word of command is, Strike the top-mast, &c.

**STROBILUS**, among botanists, a kind of pericarpium, formed of an amentum. See the article **AMENTUM**.

**AMENTUM.** It consists of a number of vaginæ, with contorted points applied to each other.

**STROPHE**, in ancient poetry, a certain number of verses, including a perfect sense, and making the first part of an ode. See the article **ODE**.

**STUMÆ**, scrophulous tumours arising on the neck and throat, constituting what is commonly called the king's evil. See the article **SCROPHULA**.

**STRUMPFIA**, in botany, a genus of plants, whose flower consists of five oblong, obtuse, patent petals, with the same number of ovate antheræ joined in a body; the fruit is a roundish, unilocular berry, crowned with the cup, and contains a roundish seed.

**STUC**, or **STUCCO**, in building, a composition of white marble, pulverised and mixed with plaster of lime; and the whole being sifted and wrought up with water, is to be used like common plaster: this is what Pliny means by *marmoratum opus*, and *albarium opus*,

**STUFF**, in commerce, a general name for all kinds of fabrics of gold, silver, silk, wool, hair, cotton, or thread, manufactured in the loom; of which number are velvets, brocades, mohairs, fattsins, taffeties, cloths, serges, &c.

**STUM**, in the wine-trade, denotes the unfermented juice of the grape, after it has been several times racked off, and separated from its sediment. The casks are, for this purpose, well matched, or fumigated with brimstone every time, to prevent the liquor from fermenting, as it would otherwise readily do, and become wine. See the article **MATCHING**.

It is this fume of the sulphur from the match, that prevents, in this case, all tendency to fermentation, and continues the natural juice of the grape in a sweet state, fit to be readily mixed with wines instead of sugar; for which purpose it is very much used in Holland, and some other countries; as also for giving a new fret, or briskness to decayed wines; so that very large quantities of this stum are annually imported to all parts, along with the foreign wines. And after the same manner a stum is prepared in England, from the juice of apples, which serves the ordinary purposes of the wine-cooper. In the preserving this liquor in this state, we see the vast use of brimstone, for it could never be done otherwise than by the matching of the casks.

Dr. Shaw gives the following method of preparing an artificial stum, nothing inferior to the natural: and as fit for the refermenting, fretting, improving, or making of wines, vinegars, and spirits. Take three pound of fine lump-sugar, or such as has been well refined from its treacle; melt it in three quarts of water, and add, in the boiling, of rhenish tartar, finely powdered, half an ounce; this dissolves with a remarkable ebullition, and gives a grateful aci-

dity to the liquor; take the vessel from the fire, and suffer it to cool, and you have an artificial must, which in all respects resembles the natural taste and sweet juice of a white flavourless grape, when well purified, and racked off from its sediment, in order to make stum. If this artificial must be stummed, that is, well fumigated with burning brimstone, it becomes a perfect stum, and may be made of any flavour, at the discretion of the artist.

**STUPOR**, a numbness in any part of the body, whether occasioned by ligatures obstructing the blood's motion, by the palsy, or the like.

**STURGEON**, *Sturio*, in ichthyology, a very large fish, growing to fourteen, sixteen, or eighteen feet in length; though the greater part are caught much smaller.

There are four cirri at the extremity of the under jaw; the eyes are large, and stand at a great distance from the extremity of the rostrum or snout: but what is very singular in the sturgeon, are the spinose tubercles, of which there are several series or rows.

**STYE**, or **STITHE**, a disorder of the eye-lids; being a small encysted tumour, about the bigness of a barley-corn.

The sty frequently occasions much pain and uneasiness, and must be treated with great caution, on account of the tenderness of the eye. Some recommend cataplasms, and the like applications; but the eye is often hurt by those, and it is observed besides, that these tubercles seldom give way to topical applications of any kind.

When they are small, Heister thinks it best to let them take their own course; but if so large as to occasion deformity, or danger of hurting the sight, the way to extirpate them, is to make a longitudinal incision on the part, and carefully take them out whole; or, if it cannot be thus got out clean, it must be cut out, as far as may be done, with scissars, and dressed with Egyptian ointment, and a little red precipitate, or touched at times with the common caustic, till eaten thoroughly away, and then the wound dressed and healed in the common manner.

This is the method by which the flat and broad-bottomed tumours of this kind are to be extirpated; and in this, great care must be taken that none of the sharp applications touch the eye, as they might injure the sight.

It is common, however, with these tumours, to hang by a sort of small root, and then they are much more easily managed, there being no more necessary than the cutting them close off with a pair of scissars, or the tying them firmly round with a piece of silk or horse-hair. They are sometimes, if taken in time, dispersed by rubbing them with fasting-spittle, or by applying the pulp of a roasted apple mixed with some saffron and camphor.

**STYGIAN LIQUORS**, an appellation given to caustic and corrosive waters, and particularly to aqua-regia. See the article **AQUA-REGIA**.

**STYLE**, a word of various significations, originally deduced from *στυλος*, a kind of bodkin, wherewith the ancients wrote on plates of lead, or on wax, &c. and which is still used to write on ivory-leaves, and paper prepared for that purpose, &c.

**STYLE**, in botany, is that part of the pistillum, or female organ of generation, which serves to elevate the stigma from the germen, on the top of which it is generally placed, and is of various figures. In some genera it is very short, as in the farracenia; and in others is entirely wanting, as in celandina and poppy. See the articles **GERMEN**, **PISTILLUM**, and **STIGMA**.

**STYLE**, in dialing, denotes the gnomon or cock of a dial, raised on the plane thereof, to project a shadow.

**STYLE**, in matters of language, a particular manner of expressing one's thoughts agreeably to the rules of syntax; or, as F. Buffier more accurately defines it, the manner wherein the words, constructed according to the laws of syntax, are arranged among themselves, suitably to the genus of the language.

From this description it appears, that the style supposes or includes the syntax; and that syntax does not extend so far as style, for the syntax may be just where the style is wretched.

A fault in style is not less a fault against grammar, than is a fault in syntax; only the former is less precise and palpable than the other. A very common error in grammarians, F. Buffier adds, is to confound two kinds of styles in one: grammatical style, or that directed by the rules of grammar; and the personal style, which depends less on the grammar than on the person that writes, whether with regard to his particular taste and genius, or with regard to his matter, or the kind or character of his work. There are a great many differences between the two; the most essential is, that the one may be diversified an infinite number of ways, and the other cannot. In effect, the personal style is naturally variable, according to the different genius, humours, and complexions.

It is the imagination that acts, that conceives, that proposes, and that expresses things, according to its character, which is different in all men, and which is to be varied according to the particular kind of the work. Hence arise the gay, the grave, the florid, the jejune, the copious, the concise, the poetical, the epistolary, and the burlesque styles. These personal styles are all independent on the grammatical; and we have authors who excel in the one, and are miserably defective in the other. The personal style is not under the direction of grammar, but of the imagination, or rather of rhetoric, that art having to do directly with our thoughts, as

grammar with our words. This, however, may be said, that grammar is far from being able to vary the same words of a phrase, with equal perfection; and that there is but one way of delivering them in the taste and genius of the language.

In oratory and poetry, style is restrained wholly to what F. Buffier calls the personal style. Language refers principally to the matter of the discourse, viz. the words; elocution to the particular members or parts thereof; and style, to the whole composition.

The masters of the art reduce the kinds of style to three; the sublime, the low, and the intermediate or equable style. The sublime style, is that consisting in magnificent words and sentences; which, by its noble boldness, ravishes the hearers, and extorts admiration, even from the unwilling. See the article **SUBLIME**.

Low, or simple style, is that ordinarily used in smaller or humbler works, as epistles, dialogues, and common discourse. The chief virtues hereof are perspicuity, smoothness, easiness, and cleanliness. It must be very sparing in the use of tropes and figures, especially the more violent ones, as the prosopopœia, apostrophe, &c.

Intermediate, or equable style, partakes of the magnificence of the sublime, and the simplicity of the low. It neither rises to the majesty of the one in words and sentences, nor yet is smartly pointed like the other. Tully calls this the polished and florid style; it being in this, that all the graces and beauties of language are principally to be used.

As to the choice of style in the general, the nature of the subject is to determine it.

Such style, says Cicero, is to be chosen, as expresses great things magnificently, middle things moderately, and low things subtilly: but more particularly, as there are three branches of the duty of an orator, to teach, to delight, and to move; the simple style is used to teach, the middle to delight, and the sublime to move.

Again, the simple or low style is fit for comedy, the sublime for tragedy, and the middle for history. Again, the simple style is fit for bucolics and eclogues, the intermediate for georgics, and the sublime for epics: which triple difference we may discern in Virgil, though he sometimes mixes them all in the *Æneid* itself, using the simple style in the fifth book, where he describes games; and the intermediate in the beginning of the poem.

Care is still to be taken that the style be not flat and dull, on pretence of being simple.

**Old-STYLE**, the Julian manner of computing times, as the

**New-STYLE**, is the Gregorian method of computation. See the articles **JULIAN**, **GREGORIAN**, **BISSEXTILE**, &c.

**STYLITES**, an appellation given to a kind of solitaries, who spend their lives seated on the tops of columns,

columns, to be, as they imagine, the better disposed for meditation, &c.

Of these we find several mentioned in ancient writers, and even as low as the eleventh century. The founder of the order was St. Simon Stylites, a famous anchorite in the fifth century, who took up his abode on a column, six cubits high; then on a second, of twelve cubits; a third, of twenty-two; and, at last, on another of thirty-six. The extremity of these columns were only three feet in diameter, with a kind of rail or ledge about it that reached almost to the girdle, somewhat resembling a pulpit. There was no lying down in it. The faquirs, or devout people of the East, imitate this extraordinary kind of life even to this day.

**STYLOGLOSSUS**, in anatomy, a muscle arising from the apex of the styloide process; and, descending obliquely to the side and root of the tongue, moves it sideways, backwards, and forwards.

**STYLOHYOIDÆUS**, in anatomy, a pair of muscles arising in the styloide process, and terminating in the horn and the base: this is often perforated by the digastric muscle of the jaw. These muscles draw laterally upwards.

**STYLOIDES**, in anatomy, an apophysis of the os petrosum; thus called, from its resembling a style or stylet.

**STYLOPHARYNGÆUS**, in anatomy, one of the six pair of muscles which serve to dilate the pharynx.

The stylopharyngæus arises from the beginning of the styloide process, and is inserted on both sides into this and into the thyroide process: it serves also to elevate as well as dilate the pharynx.

**STYPTIC**, *στυπτικόν*, in pharmacy, medicines which, by their astringent qualities, stop hæmorrhages. See the article **AGARIC**.

**STYRAX**, in botany, the storax tree. It rises with a woody stalk, twelve or fourteen feet high, covered with a smooth greyish bark, and sends out many slender ligneous branches on every side; these are furnished with oval leaves about two inches long, of a bright green on their upper side, but hoary on their under; they have no indentures, and are placed alternately on short foot-stalks: the flowers come out from the sides of the branches in bunches; they are white, monopetalous, and funnel-shaped, having a short cylindric tube, with a large spreading limb, divided into five obtuse segments: the fruit is a roundish unilocular drupe, containing two roundish acuminate nuts, which are convex on one side and plane on the other.

This tree is a native of several parts of Europe, and of the East. The gum which is obtained by making incisions on its trunk, is used in medicine. See the article **STORAX**.

**SUBALTERN**, a subordinate officer, or one who discharges his post under the command, and subject to the direction of another; such are lieutenants, sub-lieutenants, cornets, and ensigns, who

serve under the captain; but custom has now appropriated the term to those of much lower rank, as serjeants, and the like. We also say subaltern-courts, jurisdictions, &c. such are those of inferior lords, with regard to the lord paramount; hundred courts, with regard to county-courts, &c.

**SUBCLAVIAN**, *Subclavius*, in anatomy, is applied to any thing under the arm-pit or shoulder, whether artery, nerve, vein, or muscle.

Subclavius more particularly denotes a small oblong muscle lying between the clavicle and first rib. It is fixed by one end in the middle lower portion of the clavicle, at the distance of about an inch from each extremity, and by the other in the cartilage, and a small part of the bone of the first rib.

**SUBCOSTAL MUSCLE**, *Subcostales*, in anatomy. These muscles are fleshy planes of different breadths, and very thin, situated more or less obliquely on the inside of the ribs, near their bony angles, and running in the same direction with the external intercostals. They are fixed by other extremities in the ribs, the inferior extremity being always at a greater distance from the vertebræ than the superior, and several ribs lying between the two insertions. These muscles are more sensible in the lower ribs than in the upper, and they adhere closely to the ribs that lie between their insertions.

**SUBCUTANEOUS**, in anatomy, a thin membranous muscle, running under the skin, called also quadratus genæ, and platisma myoides. It arises with a pretty broad origin from the hind part of the neck, and from the pectoral muscle below the clavicle. It adheres firmly to the panniculus carnosus, from which it is not separated without difficulty, and therefore it was not anciently distinguished from it. It is inserted obliquely on each side into the lower jaw bone, near the skin, lips, and sometimes the bottom of the nose, all which parts it draws downwards and awry. A convulsion herein is called the cynic spasm. In some persons it reaches to the ears, which is the reason that some have the faculty of moving their ears which others want.

**SUBDUCTION**, in arithmetic, the same as subtraction. See **SUBTRACTION**.

**SUBDUPLERATIO**, is when any number or quantity is contained in another twice; thus 3 is said to be subduple of 6, as 6 is duple of 3.

**SUBDUPLICATE RATIO**, of any two quantities is the ratio of their square roots. See the article **RATIO**.

**SUBER**, the cork-tree, in botany. See the article **CORK-TREE**.

**SUBJECT**, *Subditus*, a person under the rule and dominion of a sovereign prince or state.

**SUBJECT**, *Subiectum*, is also used for the matter of an art or science, or that which it considers, or wherein it is employed: thus the human body is the subject of medicine. In this sense the anatomists call

call the body they are dissecting, and whereon they read lectures, their subject. The subject of logic is thinking or reasoning; but more particularly in a syllogism one of the terms of a proposition is called the subject, and the other the attribute. In poetry, the subject is the matter treated of, or the event related or set to view. Subject also denotes the substance or matter to which an accident is added, whence the maxim that two contraries can never subsist in the same subject.

**SUBJUNCTIVE**, in grammar, the second mood of verbs, thus called because subjoined to another verb, or particle at least, and not standing alone in a sentence: thus, *Orat ut ad se venias. Quid faciam prorsus ignoro. Though this were true, &c.*

**SUBLIMATE**, a chemical preparation, the basis whereof is mercury or quicksilver.

There are two kinds of sublimate, corrosive sublimate, and sweet sublimate, or mercurius dulcis sublimatus; which see under **MERCURY**.

**SUBLIMATION**, the condensing and collecting in a solid form, by means of vessels aply constructed, the fumes of bodies raised from them, by the application of a proper heat.

Sublimation is in all respects the same with distillation, except that in the first the produce is solid, but in the latter fluid. The only variation, therefore, necessary in the operation, is the accommodating the recipient part of the apparatus to this difference, which admits, in most cases, that one vessel may perform the office both of condenser and receiver, as the matter cannot, like fluids, flow to another part, but must remain where it first settles, except in some instances, where the matter is extremely volatile, or where a fluid rising with it renders a depending receiver necessary.

The vessels proper, in respect of the different subjects of this operation, vary in their structure and the substance of which they are made, as well on account of the degree of heat requisite to be employed, as the nature of the matter to be sublimed, since corrosions of them are here, and indeed in all other cases, to be carefully avoided.

In sublimations of mercury, whether combined with acids or sulphur, of sal ammoniacum and of sulphur alone, a single vessel may answer all the purposes, as their necessity of a great heat to keep them in the condition of fumes, renders the upper part of the glass capable of detaining them when they are raised thereto; but it is proper, in these instances, that a glass in sand, or earthen ware, should be used. A glass body, in a strong sand heat, may very well serve for all these; but sublimate of mercury is frequently sublimed in a bolt-head, or mattrass; and the factitious cinnabar, by those who make large quantities, in an earthen vessel made in the shape of an egg.

In the sublimation of volatile salt of amber, and flowers of Benjamin, a container and condenser are

separately necessary, and may in all these cases be extremely well supplied by a retort and receiver, though bodies with alembic heads, and receivers of glass fitted to them, have been generally recommended in several of them; but the trouble of luting two junctures, and the difficulty of fitting them to each other, with several other reasons, make retorts far more convenient. A retort and receiver are likewise proper in the case of cinnabar of antimony; for though the cinnabar might be restrained in one glass, the butter of antimony makes the receiver necessary.

In sublimations of factitious cinnabar, mercury sublimate, and sal ammoniacum, it is sufficient to cover the aperture or neck of the vessel with a tile; and in the sublimation of cinnabar of antimony, and flowers of Benjamin, in retorts, it is unnecessary to lute on the receiver; but in the sublimation of volatile salts, it is requisite to lute the vessels as secure as possible, leaving only a small vent till they attain the greatest heat they are to suffer during the operation.

The requisite degree of heat in sublimation varies in almost every different subject of the operation. The limits are from the greatest degree that can be given in sand, to a degree something less than that which will make water boil.

Hoffman observes, that only those things are sublimable which contain a dry exhaleable matter in their original construction, and among these is found a great variety, which require various methods and means to execute that effect.

Among the minerals, sulphur, antimony, and orpiment, are named as the principal sublimable bodies: these are of a very lax compage or structure, and easily raised by fire in small particles, which concrete again on being stopped from flying off by the cover of the vessel; while, on the contrary, iron, silver, and the other metals, being of a closer structure, remain fixed in the greatest heat, and never ascend without being mixed with some volatile substance, that is of itself capable of rising and taking up some of them with it. Thus copper and iron will be raised in sublimation by means of sal ammoniac mixed with them; and even gold itself is said to be subject to the same law; Mr. Boyle assuring us, that he had a secret method of preparing a certain saline substance, by means of a very small admixture of which, gold would be made to rise in sublimation, and form fine purple crystals.

The admixtures which make bodies sublimable that are not so in themselves, are to be of various kinds, according to the nature of the body to be sublimed. Among these, some act by rendering the body more easily fusible, and disuniting those particles more readily which the fire is expected to carry up: others act again by preventing the cohesions of the particles of the substance to be sublimed, which heat would otherwise occasion: and, finally, others,

## S U B

by entering the body of the fixed substance they are mixed with, and giving wings, as it were, to its subtle particles, so that they may ascend with its easily-sublimable matter, and join with it in the formation of one mixed substance in the top of the vessel, by partaking of the nature of both. Others act potentially in the same way, but by different means, themselves not-being capable of sublimation, but acting on the substance to be sublimed, by enervating, weakening, or absorbing those substances, or parts, of the mixed body, which would otherwise have prevented the ascent of the rest: and, finally, some act as dissolvents only, and by that means render things easy of sublimation, which would have been very difficultly so, while their parts were in a more strict continuity.

**SUBLIME**, in discourse, is defined by Boileau, to be something extraordinary and surprising, which strikes the soul, and makes a sentiment or composition ravish and transport.

From this definition it appears, that the sublime is a very different thing from what the orators call the sublime style. The sublime style necessarily requires big and magnificent words; but the sublime may be found in a single thought, a single figure, a single turn of words. A thing may be in the sublime style, and yet not be sublime; that is, it may have nothing extraordinary and surprising.

Longinus makes five sources of the sublime: the first, a certain elevation of the mind, which makes us think happily: the second is the pathetic, or that natural vehemence and enthusiasm which strikes and moves us; these two are wholly owing to nature, and must be born with us; whereas the rest depend partly on art: the third is the turning of figures in a certain manner, both those of thoughts and of speech: the fourth, nobleness of expression; which consists of two parts, the choice of words, and the elegant figurative diction: the fifth, which includes all the rest, is the composition and arrangement of the words in all their magnificence and dignity.

**SUBLINGUAL GLANDS**, in anatomy, two glands under the tongue, placed one on each side thereof. These, called also hypoglossides, filtrate a serous humour of the nature of saliva, which they discharge by little ducts near the gums into the mouth.

**SUBMULTIPLE**, in geometry, &c. A submultiple number, or quantity, is that which is contained a certain number of times in another, and which, therefore, repeated a certain number of times, becomes exactly equal thereto: thus 3 is a submultiple of 21; in which sense submultiple coincides with an aliquot part.

**SUBMULTIPLE RATIO**, is that between the quantity contained and the quantity containing: thus the ratio of 3 to 21 is submultiple. In both cases submultiple is the reverse of multiple, 21, e. g.

## S U B

being a multiple of 3, and the ratio of 21 to 3 a multiple ratio. See the article **RATIO**.

**SUBNORMAL**, in geometry, a line which determines the point in the axis of a curve, where a normal or perpendicular, raised from the point of contact of a tangent to the curve, cuts the axis. Or the subnormal is a line which determines the point wherein the axis is cut by a line falling perpendicularly on the tangent in the point of the contact.

**SUBPŒNA**, in law, a writ whereby all common persons, or those under the degree of peerage, may be called into chancery, in any case where the law cannot afford a remedy.

**SUBREPTION**, *Subreptio*, the act of obtaining a favour from a superior, by surprise, or a false representation. See the next article.

**SUBREPTITIOUS**, or **SURREPTITIOUS**, a term applied to a letter, licence, patent, or other act, fraudulently obtained of a superior, by concealing some truth, which, had it been known, would have prevented the concession or grant; in which case, the benefits of letters, licences, &c. are forfeited.

**SUBROGATION**, or **SURROGATION**, in the civil law, the act of substituting a person in the place, and entitling him to the rights, of another: but, in its general sense, subrogation implies a succession of any kind, whether of a person to a person, or of a person to a thing.

**SUBSCAPULARIS**, in anatomy, a muscle arising from the basis and side of the scapula, and, spreading itself under the whole convex or under-side of it, is inserted by a semi-circular tendon, into the neck of the os humeri, and draws it down to the side of the trunk.

**SUBSCRIPTION**, in general, signifies the signature put at the bottom of a letter, writing, or instrument.

In commerce, it is used for the share or interest, which particular persons take in a public stock, or a trading company, by writing their names, and the shares they require, in the books or register thereof.

Subscription, in the commerce of books, signifies an engagement to take a certain number of copies of a book intended to be printed, and a reciprocal obligation of the bookseller, or publisher, to deliver the said copies, on certain terms.

**SUBSEQUENT**, something that comes after another, particularly with regard to the order of time.

**SUBSIDY**, in law, signifies an aid or tax granted to the king, by parliament, for the necessary occasions of the kingdom; and is to be levied on every subject of ability, according to the rate or value of his lands or goods: but this word, in some of our statutes, is confounded with that of customs.

**SUB-**

**SUBSISTENCE**, in the military art, is the money paid to the soldiers weekly, not amounting to their full pay; because their cloaths, accoutrements, tents, bread, &c. are to be paid. It is likewise the money paid to officers upon account, till their accounts be made up, which is generally once a year, and then they are paid their arrears.

**SUBSTANCE**, *Substantia*, something that we conceive to subsist of itself, independently of any created being, or any particularly mode or accident.

Our ideas of substances, Mr. Locke observes, are only such combinations of simple ideas, as are taken to represent distinct things subsisting by themselves, in which the confused idea of substance is always the chief. Thus the combination of the ideas of a certain figure, with the powers of motion, thought, and reasoning joined to the substance, make the ordinary idea of a man: and thus the mind observing several simple ideas to go constantly together, which being presumed to belong to one thing, or to be united in one subject, are called by one name, which we are apt afterwards to talk of, and consider, as one simple idea.

We imagine these simple ideas do not subsist by themselves, but suppose some substratum wherein they subsist, which we call substance. The idea of pure substances is nothing but the supposed, yet unknown support of these qualities, which are capable of producing simple ideas in us. The ideas of particular substances are composed out of this obscure and general idea of substance, together with such combinations of simple ideas, as are observed to exist together, and supposed to flow from the internal constitution and unknown essence of that substance. Thus we come by the ideas of man, horse, gold, &c. Thus the sensible qualities of iron, or a diamond, make the complex ideas of those substances, which a smith, or a jeweller, commonly knows better than a philosopher. The same happens concerning the operations of the mind, viz. thinking, reasoning, &c. which we concluding not to subsist by themselves, nor comprehending how they can belong to body, or be produced by it, we think them the actions of some other substance, which we call spirit, of whose substance or nature we have as clear a notion as of that of body, the one being but the supposed substratum of the simple ideas we have from without, as the other of those operations which we experience in ourselves within; so that the idea of corporeal substance in matter, is as remote from our conceptions, as that of spiritual substance.

Hence we may conclude, that he has the most perfect idea of any particular substance, who has collected most of those simple ideas which do exist in it, among which we are to reckon its active powers and passive capacities, though not strictly simple ideas.

Substances are generally distinguished by secondary qualities, for our senses fail us in the discovery of primary ones, as the bulk, figure, texture, &c. of the minute parts of bodies, on which their real constitutions and differences depend: and secondary qualities are nothing but powers with relation to our senses. The ideas that make our complex ones of corporeal substances, are of three sorts: first, the ideas of primary qualities of things, which are discovered by our senses; such are bulk, figure, motion, &c. Secondly, the sensible secondary qualities, which are nothing but powers to produce several ideas in us, by our senses. Thirdly, the aptness we consider in substance, to cause or receive such alterations of primary qualities, as that the substance so altered, should produce in us different ideas from what it did before; and they are called active and passive powers: all which, as far as we have any notice or notion of them, terminate in simple ideas.

Besides the complex ideas we have of material substances, by the simple ideas taken from the operations of our own minds, which we experience in ourselves, as thinking, understanding, willing, knowing, &c. co-existing in the same substance, we are able to frame the complex idea of a spirit; and this idea of an immaterial substance is as clear as that we have of a material one. By joining these with substance, of which we have no distinct idea, we have the idea of spirit; and by putting together the ideas of coherent, solid parts, and a power of being moved, joined with substance, of which likewise we have no positive idea, we have the idea of matter. See **MATTER**.

Further, there are other ideas of substances, which may be collective; which are made up of many particular substances considered as united into one idea, as a troop, army, &c. which the mind makes by its power of composition. These collective ideas are but the artificial draughts of the mind, bringing things, remote and independent, into one view, the better to contemplate and discourse of them united into one conception, and signified by one name; for there are no things so remote, which the mind cannot, by this art of composition, bring into one idea; as is visible in that signified by the name universe.

**SUBSTANTIAL**, in the schools, something belonging to the nature of substance.

**SUBSTANTIVE**, in grammar, a noun, or name, considered simply and in itself, without any regard to its qualities, or other accidents, in contradistinction to the noun termed adjective, or that which expresses a certain quality or accident of the noun substantive. Or, a noun substantive is that noun, which, joined to a verb, makes a perfect sentence, as *a man, a horse, a tree*; thus, *a man laughs, a horse gallops, a tree buds*, are each of them perfect

# S U B

perfect sentences. All nouns, to which one cannot add the word *thing*, are substantives; and those to which *thing* may be added, are adjectives.

**SUBSTITUTE**, a person appointed to officiate for another, in case of absence, or other legal impediment.

**SUBSTITUTE**, in medicine, denotes a drug or remedy that may be used instead of another; or that supplies the place of another, of like virtue, which is not perhaps to be had: called also succedaneum.

**SUBSTITUTION**, in grammar, the using one word for another. This the grammarians otherwise call syllepsis.

**SUBSTITUTION**, in the civil-law, a disposition of a testament, whereby the testator substitutes one heir for another, who has only the usufruct, and not the property of the thing left him.

**SUBSTITUTION**, in algebra, is the putting, in the room of any quantity in an equation, some other quantity, which is equal to it, but expressed in another manner.

**SUBTRACTION**, or **SUBTRACTION**, in arithmetic, the second rule, or rather operation, in arithmetic, whereby we deduct a less number from a greater, to learn their precise difference.

**Prob. I.** To subtract integers of like names, when the minuend, or number to be subtracted from, is greater than, or equal to, the subducend, or that which is subtracted.

**Rule 1.** Place the subducend under the minuend, and draw a line under both. 2. Begin at the right hand; take the less from the greater, or equals from equals, and set the difference of each row underneath.

Example in integers alone.

Minuend 638  
Subducend 213

Remainder 425

**Prob. II.** To subtract integers of the same name or denomination, when some of the minuend numbers are less than their inferior in the subducend.

**Rule 1.** Place your numbers, and begin as before. 2. According to their respective value, take one of the next denomination, out of which subtract, and to the remainder add, the minuend, setting their sum underneath. 3. Then add what you took, to the next place, on the left hand, and so proceed by this, or the former rule.

Example in integers alone.

From 2537  
Subtract 1648

Remainder 889

For, by saying 8 from 17, I add 10 to the minuend; but I add also the same to the subducend, by saying, 1 and 4 = 5, therefore the remainder must be the same.

# S U B

For by adding a ten to the units, and taking it away from the tens, the value of the number is not changed.

Examples in integers and parts.

|       | s. | d. |       | l.  | s. | d. |
|-------|----|----|-------|-----|----|----|
| From  | 5  | 3  | From  | 246 | 3  | 4  |
| Subt. | 2  | 9  | Subt. | 68  | 10 | 6  |
| Rem.  | 2  | 6  | Rem.  | 177 | 12 | 10 |

**Theorem.** In subtraction, the subducend, together with the remainder, is equal to the minuend. For all the parts taken together are equal to the whole. And if the subducend be taken from the minuend, there rests the remainder. But if a part be taken from the whole, the remainder will be the other part; therefore, the subducend, together with the remainder, are all the parts of the minuend, and consequently equal to it.

**Corollary.** Hence addition and subtraction serve reciprocally to prove each other. See the article **ADDITION**.

For addition and subtraction are opposite in all cases; and what is done by one, is undone by the other.

|                                              |                                                         |
|----------------------------------------------|---------------------------------------------------------|
| Thus, if to 6<br>be added 4<br>the sum is 10 | And if from 10<br>be subtracted 4<br>the remainder is 6 |
|----------------------------------------------|---------------------------------------------------------|

That is, if  $6 + 4 = 10$ , then  $10 - 4 = 6$ .

**SUBTRACTION**, in algebra, is performed by the following general rule: Change the signs of the quantity to be subtracted, into their contrary signs, and then add it, so changed, to the quantity from which it was to be subtracted, by the rules of addition; the sum arising by this addition is the remainder.

For to subtract any quantity, either positive or negative, is the same as to add the opposite kind. See the article **ADDITION**.

Examples.

|                                                                                 |                                      |
|---------------------------------------------------------------------------------|--------------------------------------|
| From $+5a$<br>Subt. $+3a$<br>Rem. $5a - 3a$ , or $2a$                           | $8a - 7b$<br>$3a + 4b$<br>$5a - 11b$ |
| From $2a - 3x + 5y - 6$<br>Subt. $6x + 4x + 5y + 4$<br>Rem. $-4a - 7x$ $0 - 10$ |                                      |

It is evident, that to subtract, or take away a decrement, is the same thing as adding an equal increment. If we take away  $-b$  from  $a - b$ , there remains  $a$ ; and if we add  $+b$  to  $a - b$ , the sum is likewise  $a$ . In general, the subtraction of a negative quantity is equivalent to adding its positive value.

**SUBSTYLAR LINE**, in dialing, the line whereon the style, or gnomon, of a dial is duly erected.

SUB-

**SUBTANGENT** of a *Curve*, in the higher geometry, is the line which determines the intersection of the tangent with the axis; or, that determines the point wherein the tangent cuts the axis prolonged. See the article *CURVE*.

**SUBTENSE**, in geometry, the same with the chord of an arch.

Hence, the subtense of an angle is a right line supposed to be drawn between the two extremities of the arch that measures that angle.

**SUBTERRANEAN**, or **SUBTERRANEAN**, appellations given to whatever is under-ground: thus, naturalists speak of subterranean fires, damps, &c.

**SUBTILE**, in physics, an appellation given to whatever is extremely small, fine, and delicate; such as the animal spirits, the effluvia of odorous bodies, &c. are supposed to be.

**SUBTRIPLE RATIO**, is when one number, or quantity, is contained in another three times: thus, 2 is said to be subtriple of 6, as 6 is triple of 2.

**SUBULARIA**, in botany, a genus of tetradynamous plants, whose flower consists of four ovate intire petals, disposed in the form of a cross; the germen is ovate, with scarce any style; and the stigma is obtuse: the fruit is an oval compressed pod, having two cells, which contain a few very small roundish seeds.

**SUBULATED**, something in the shape of an awl: thus, a subulated leaf is one of an oblong and narrow figure, broadest at the base, and thence gradually decreasing, till it terminates in a point.

**SUCCEDANEUM**, in pharmacy, denotes a drug substituted in the place of another, in medical composition.

**SUCCESSION**, *Successio*, in philosophy, an idea which we get by reflecting on that train of ideas constantly following one another in our minds, when awake. See the article *IDEA*.

**SUCCESSION**, in law, implies a right to the whole effects left by a defunct.

**SUCCESSOR**, in law, one that succeeds, or comes in the place of, another.

It is held, that a sole corporation may take an estate in fee to them and their successors, but not without the word *successors*: whereas an aggregate corporation may take a fee in succession, without expressing the word *successors*; and likewise may have goods and chattels in succession. See the article *CORPORATION*.

**SUCCINUM**, amber, in natural history. See *AMBER*.

**SUCCISA**, in botany and pharmacy, a species of scabiosa, called by some *morfus diaboli*, devil's bit; and said to be alexipharmic, but is little used in the present practice.

**SUCCORY**, *Cichorium*, in botany, &c. See *CICHORIUM*.

**SUCCULA**, in mechanics, a bare axis, or cylinder, with staves to move it round; but without any tympanum or peritrochium.

**SUCCULENT PLANTS**, in botany, those whose leaves are very thick and full of juice; such are the aloes, &c.

**SUCK-FISH**, *Remora*, in ichthyology. See the article *REMORA*.

**SUCKERS**, in gardening, the same with offsets. See the article *OFF-SETS*.

**SUCKING-PUMP**. See *PUMP*.

**SUCTION**, *Suflio*, the act of sucking or drawing up a fluid, as air, water, milk, or the like, by means of the mouth and lungs.

**SUCULA**, or **SUCCULA**. See the article *SUCCULA*.

**SUDAMINA**, little heat pimples in the skin, like the millet-grains, frequent in youth, especially those of a hot temperament, and that use much exercise.

**SUDATORY**, *Sudatorium*, a name given by the ancient Romans to their hot or sweating-rooms; sometimes also called *loconica*. See the article *BATH*.

**SUDOR**, sweat, in physiology. See the article *SWEAT*.

**SUDOR ANGLICANUS**, the sweating-sickness, a disease so called from its appearing first in England, in the year 1483.

It seized different patients in different manners; for in some it first appeared with a pain in the neck, scapula, legs, or arms; whilst others perceived only a kind of warm vapour, or flatulence, running through those parts. And these symptoms were suddenly succeeded by a profuse sweat, which the patient could not account for. The internal parts became first warm, and were soon after seized with an incredible heat, which thence diffused itself to the extremities of the body. An intolerable thirst, restlessness, and indisposition of the heart, liver, and stomach, were the next symptoms, which were succeeded by an excessive head-ach, a delirium, in which the patient was very trifling and talkative; and after these, a kind of extenuation of the body, and an irresistible necessity of sleeping.

For preventing this disease, temperance is ordered, and the choice of salutary aliments and drinks. No crude pot-herbs or sallads are to be used, because they may have received a noxious quality from the air; or, if they are used, they are to be previously washed with warm water.

**SUDORIFIC**, in pharmacy, an appellation given to any medicine that causes or promotes sweat.

Sudorific, perspirative, and alexipharmic medicines, says Dr. Shaw, make a large part of the common dispensaries. A few medicines well chosen, might supply the place of all these; and of these, the principal one would prove to be camphor, which

which trial will always shew to be greatly superior to bezoar, Gascoign's powder, lapis contrayerva, and the like.

The same gentleman gives the following easy method of preparing a safe and effectual sudorific: take an ounce of refined camphor, beat it in a marble mortar, with two ounces of blanched almonds, till it be reduced to a smooth and even paste. This may be formed into pills, or boluses, and given, according to the strength of the patient, and other considerations, from three grains to forty.

SUET, *Sevum*, or *Sebum*, in anatomy, the solid fat found in several animals, as sheep, oxen, &c. but not in the human species.

SUFFOCATION, in medicine, the privation of respiration, or breathing; which is sometimes occasioned by a congestion of blood in the lungs, so as to prevent the ingress of the air. See the articles ASTHMA, CATARRH, QUINZY, &c.

SUFFOCATION of the *Womb*, or *Matrix*, is a disease pretty frequent in women, called also fits of the mother. See the article HYSTERIC.

SUFFRAGAN, an appellation given to simple bishops, with respect to archbishops, on whom they depend, and to whom appeals lie from the bishop's courts.

SUFFRAGE, *Suffragium*, denotes a vote given in an assembly, where something is deliberated on, or where a person is elected to an office or benefice.

SUFFRUTEX, among botanists, denotes an under-shrub, or the lowest kind of woody plants, as lavender, rue, &c.

SUGAR-CANE, *Saccharum*, in botany, a genus of plants, the corolla of which is composed of two oblong, acuminate, concave, chaffy valves, containing three capillary filaments topped with oblong antheræ: there is no pericarpium, but each flower contains an oblong, narrow, acute-pointed seed.

The root of the sugar-cane is jointed like those of the reed, from which arises several shoots, to the height of eight, nine, or ten feet, according to the goodness of the land where they grow; the stalks are jointed, and the leaves which are placed at each joint, are long, narrow, of a yellowish-green colour, armed with very small sharp serratures, and have each a deep whitish furrow, or hollow midrib, which is broad and prominent on the under side: the flowers are produced in panicles at the top of the stalks; these are from two to three feet long, and composed of many spikes, nine or ten inches long, which are again subdivided in smaller ones; these have long down which incloses the flowers.

It grows spontaneously in both the Indies, and is cultivated in great quantities in the British and French islands in the West-Indies. It is propagated there by cuttings or joints of proper lengths; these are from fifteen to twenty inches long, in proportion

to the nearness of their joints or eyes: these cuttings are generally taken from the tops of the canes, just below the leaves, but if they are chosen from the lower part, where they are less succulent and better ripened, they would not produce so luxuriant canes, but their juice would be less crude, and contain a greater quantity of salts.

The distance which the canes are usually allowed in planting, is from three to four feet, row from row, and the hills are about two feet asunder in the rows; in each of these hills they plant several cuttings. The time for planting the canes is always in the rainy seasons. The method practised in planting them is to make a trench with a hoe, which is performed by hand; into this a negro drops the number of cuttings intended for planting, at the distance the hills are designed; these are, by other negroes, placed in their proper position, and afterwards the earth is drawn up over them. The ground is occasionally to be kept clear from weeds, and in eight or ten months the canes are fit to cut, to make sugar from them, which is properly the essential salt of the cane, as tartar is of the grape. See TARTAR.

The manner in which sugar is made, is thus: They cut off the reeds at one of the joints near the roots; they are then cleared of the leaves, and tied up in bundles, and sent to the mills, which are worked either by water or horses.

The sugar-mill is composed of three rollers of an equal size, and all armed with iron plates, where the canes are to pass between them; only the middle roller is much higher than the rest, to give the larger sweep to the two poles to which the horses are yoked. This great roller in the middle is furnished with a cog full of teeth, which catch the notches in the two side rollers, and force them about to bruise the canes, which pass quite round the great roller, and come out dry and squeezed from all their juice; which runs into a vessel or back under the mill, and is thence conveyed through a narrow spout into the first boiler.

After the juice is let out of the first vessel, it is received into another, in which it is boiled more briskly, and skimmed from time to time with a large kind of spoon, pierced with holes to let the liquor through, while it retains the scum and foulness separated from it in boiling: towards the end of this boiling, they throw into it a strong lixivium of wood ashes, with some quick-lime among it; this greatly promotes the separation of the foulness that yet remains among it; and, after it has boiled some time with this addition, they strain it off. The fæces left in the cloths, make a kind of wine, when fermented properly with water. The strained liquor which is now tolerably clean, is let into a third boiler, in which it is boiled down to the consistence of sugar over a very brisk fire, the people who

who attend it continually stirring and scumming it.

Great caution is to be used that the boiling matter does not rise over the sides of the vessel, which would be of very dangerous consequence: they prevent this by taking up quantities of the boiling matter with a ladle, lifting it up high, and letting it run in again, and by now and then adding a small piece of butter, or fat of some kind, which takes down the bubbling almost instantaneously. They are very careful that no lemon-juice, or any other acid of that kind, comes near the vessels, a very small admixture of that being sufficient to keep the matter from granulating.

When the liquor is boiled enough, which is known by its concreting on throwing a spoonful of it up into the air, it is then let out into a fourth vessel, under which there is a very gentle fire, only kept up that it may have leisure to granulate: when it has begun to granulate, it is let out of this last boiler into a kind of conic earthen vessels, open at both ends; the widest aperture is placed upwards, and the smaller end downwards, its aperture being stopped with a wooden plug.

It is left in these vessels twenty-four hours to concreate; after this, they are removed into sugar-houses, and are there arranged in regular order, with a vessel of earthen-ware under each; the plug is then taken out of the bottom aperture of each, and they are left in this condition for about forty days, that all the thick liquor, or melasses, may run from them: after they have stood thus long to drain of themselves, a quantity of clay is diluted, with water, into a thin paste, and this is poured on the top of every parcel of sugar in the vessels, so as to cover it two or three inches deep. This water, by degrees, all leaves the clay, and penetrating into the mass of sugar, runs through it, and carries off yet more of this foul thick liquid with it, into the vessels placed underneath to receive it.

When the clay is quite dry, it is taken off, and the first preparation of the sugar is now finished; they shake it out of the vessels, and, cutting it into lumps, which are of a dirty, brownish, or greyish colour, they put it up in hogheads, and other casks, under the name of grey or brown sugar.

The sugar, in this state, ought to be dry, not unctuous, and to have no taste of burning. The liquor, which has run from the sugar in standing, is boiled to a consistence, and sold under the name of melasses, or treacle; this affords, by fermentation, a very clean and good spirit. See the article **MELASSES**.

This coarse sugar is afterwards refined to various degrees of purity by new solutions, and is sold at different prices, and under different names, according to the degree of purity it is brought to. Our sugar refiners first dissolve it in water, then clarify the solution by boiling with whites of eggs and despu-

mation; and after due evaporation, pour it into moulds; where the fluid part being drained off, and the sugar concreated, its surface is covered with moist clay, as before. The sugar thus once refined, by repetition of the process, becomes the double-refined sugar of the shops.

The candy-sugar, or that in crystals, is prepared by boiling down solutions of sugar to a certain pitch, and then removing them into a hot room, with sticks placed across the vessel for the sugar to shoot upon: and these crystals prove of a white or brown colour, according as the sugar used in the process is pure or impure.

A pound of sugar purified to the highest degree, and distilled in a retort, yields first about half an ounce of a limpid insipid phlegm, without smell; and after this, comes over a liquor, at first limpid and colourless, afterwards reddish, and, finally, of an empyreumatic smell, in quantity not less than six ounces; this is partly of an acid, partly of an alkaline and urinous taste: after this, comes over a thick and reddish oil, in quantity about three drams; and then more than an ounce of a brown oil of a thicker consistence. The remainder in the retort, calcined and lixiviated, yields a dram of a pure alkaline salt.

Sugar is a true salt, and when perfectly pure, after solution, it concretes into regular crystals; these are of a prismatic figure, and consist of eight plain surfaces, in two of which the opposite bases are equal and parallel, the rest are parallelograms. In its natural state, it manifests not the least token of any thing, either acid or alkaline. It is inflammable, in a great degree, burning with a very brisk white flame. It dissolves with the utmost readiness, in all aqueous menstrooms, but very difficultly in spirituous or oily liquors: mixed with water, it, after a time, ferments, and acquires a vinous flavour; and at this time, an inflammable spirit, like that of wine, may be drawn from it in a considerable quantity.

Many other plants and trees might be found which would yield sugar: thus several species of maple afford a juice which boils into good sugar. But the great quantity of it yielded by the sugar-cane, and its easy culture, renders it unnecessary to look farther after what it so abundantly supplies us with.

The uses of sugar, as a sweetner, are sufficiently known: it promotes the union of distilled oils with watery liquors, and prevents the separation of the butyraceous parts from milk; and hence it is supposed to unite the unctuous part of the food with the animal juices. Sugar is not only innocent, but reconciles to the palate and stomach, substances, of themselves, disgusting to both; and the impure sorts, in consequence of their containing an unctuous or oily matter, prove emollient and laxative. The crystals are the most difficult of solution, and consequently.

quently are most proper, where this lubricating sweet is wanted to dissolve slowly in the mouth.

The medicinal preparations of sugar are, 1. Sugar of roses, *saccharum rosaceum*, thus made: take of red rose buds, freed from the heels, and hastily dried, one ounce; and of double refined sugar, one pound: reduce them separately into powder, then mix and moisten them with water, that they may be formed into troches, which are to be dried with a gentle heat.

2. Red sugar of roses, *saccharum rosatum rubrum*, is made thus: take of white sugar, one pound; juice of red-roses, four ounces; and red-roses dried, one ounce: boil the sugar and juice over a gentle fire, till the juice is almost all evaporated; then throw in the dry roses reduced to a very fine powder. Pour out the matter upon a marble, and form it into lozenges according to art.

These preparations are chiefly valued for their agreeableness to the eye and palate: some likewise esteem them, medicinally, as light restringents; and look upon them, not undeservedly, as an excellent addition to milk, in phthical and hectic cases. Some have been accustomed to add a portion of acid, which improves their colour, but at the same time renders them less proper to be used with milk.

3. Barley-sugar, *saccharum hordeatum seu penidiatum*, is made by boiling white sugar in barley-water, i. e. a decoction of barley, till it acquires such a consistence, as that it may be drawn out, and twisted into threads or strings: this is rarely prepared by the apothecaries, or considered as a medicine.

*SUGAR of Lead, Saccharum Saturni.* See the article SACCHARUM.

Sugar of lead is thus ordered to be made in the London Dispensatory: boil cerus with distilled vinegar, till the vinegar becomes sufficiently sweet; then filter the vinegar through paper, and after due evaporation, set it to crystallize.

**SUGILLATION**, in medicine, an extravasation of blood in the coats of the eye, which at first appears of a reddish colour, and afterwards livid or black. If the disorder is great, bleeding and purging are proper, as are discutients. The following cataplasm is said to be very good: Take of comfrey-root, six ounces; of Solomon's seal, two ounces; of elder-flowers, one ounce and a half; of bean-flour, one ounce; let all these be boiled in a sufficient quantity of spring-water. The decoction may be used as a foment, and the ingredient for a cataplasm.

**SUIT**, in law, is used in different senses, as, 1. For an action, whether personal or real. 2. Suit of court, or suit-service, which is an attendance the tenant owes to his lord's court. 3. Suit-covenant, where a person has covenanted to do service in the court of the lord. 4. Suit-custom, which is where

one and his ancestors have owed suit time out of mind. 5. It is used for a petition to the king, or any person of dignity; where a lord distrains his tenant for suit, and none is due; in this case, the party may have an attachment against him to appear in the king's court. 6. Suit of the king's peace, is an action brought against a person for breach of the king's peace; as in the case of treasons, felonies, or trespasses.

**SUIT-SILVER**, a small sum paid in some manors, to excuse the appearance of freeholders at their lord's courts.

**SULPHUR**, in natural history, a genus of fossils, defined to be dry, solid, but friable fossil bodies; melting with a small heat, when fired in the open air; burning almost wholly away with a blue flame, and noxious vapour; and indued with an electric power, and not dissoluble in acids.

Some have used the word sulphur as a name for the whole series of inflammable bodies, but as we have also been used to distinguish those of a particular kind by the same name, it seems much more eligible to restrain that name to those bodies, and to give some other for the more general classes.

The word sulphur, in this acceptation, becomes the name of a regular genus of fossils, of which there are four known species. 1. The yellow native sulphur, which in its purest state is of a pale straw-colour, and as pellucid as the finest amber; but is more frequently found coarser, and more opaque. It is found in the gold mines of Peru; in Hungary, and in some other places. 2. The green native sulphur. This is harder than the other, and is usually found in small masses composed of several crusts. It is found, so far as is yet known, only about mount Vesuvius. 3. The grey native sulphur, which is common in Iceland, and many other places, and is the coarsest and worst of all the kinds. And 4. The most rare and beautiful of all the kinds, the red native sulphur. This is of a fine glowing red, like cinnabar, and very bright and transparent, and is found, so far as is yet known, only in the gold mines of Peru.

But besides these native kinds of sulphur, there is a factitious sort, by far the most common in the shops, separated from extraneous matters by means of fire. It is sometimes met with in very large masses, and called sulphur in the cake; but what we most frequently see of it is in oblong cylindric rolls of a yellow colour, sometimes with, and sometimes without, an admixture of greenish. The yellow contains less, the greenish more, of the vitriolic salt mixed with it; it is friable, and affords a sort of crackling noise, when rubbed between the fingers; it is very easily reduced to powder, and melts with a small degree of heat. It may be totally sublimed, in a close vessel, without alteration. It takes fire on being brought into contact with a burn-

burning coal, or any ignited matter; and when pure and genuine, for we are liable to great cheats in regard to it, it does not burn away very quickly, but continues a considerable time, emitting a deep blue flame. It is to be chosen for internal use of the purest and brightest yellow, light, easily broken, and appearing very bright and glossy where it breaks. If it be for making oil of sulphur, the greenish rolls are the best, as containing most acid.

This kind of sulphur is separated, by means of fire, from various minerals, which are found naturally to contain it.

The greatest part of what we have, is made from the common vitriolic pyrites, the same mineral yielding both sulphur and vitriol, and often alum. They first give it a degree of fire sufficient to melt the sulphur it contains, and, when this is all run out into vessels prepared to receive it, they expose the remaining matter to the air, after which they boil it in water, and obtain from the lixivium the common green vitriol or copperas; and after all this is obtained, by adding an alkali to the same liquor, they get alum from it. See the articles VITRIOL and ALUM.

Sulphur, under whichever of these forms it appears, is still the same in all its characters; it dissolves in oils, and alkaline substances; it grows red when melted, but turns yellow again when it cools; it affords an acid, the same with that of vitriol, if its fumes in burning be caught in a proper manner; but it will not yield this acid by the common way of distillation.

Sulphur, melted with gold, provided that metal be pure, makes no sort of alteration in it; but this is the only metal that escapes its effects. Thrown upon silver heated red hot, the metal immediately melts, and, if taken from the fire as soon as it does so, it will be found, when cold, to resemble lead rather than what it really is. It retains its malleability perfectly, and cuts easily with a knife; but it is of a dull bluish colour. It is, however, easily reduced again to its proper appearance; for there requires no more to this, than the keeping it a few minutes in a strong fire to burn away the sulphur. If the heat is slackened towards the end of this fusion, the silver will not fall into one uniform mass, but will rise up in small sprigs all over the surface in a very beautiful manner, resembling the branches of silver, sometimes seen on the surface of ores. Tin melted with brimstone, if the metal be first granulated, and the brimstone added in powder in three times its quantity, deflagrates as if nitre had been mixed with it. The remainder becomes solid, while yet in the fire, and, when cold, is a brittle regulus of the colour of lead, and greatly resembling a semi metal in its qualities. Tin may indeed be wholly turned into scoria by burning it with additional parcels of sulphur. Sulphur melted along with lead destroys its malleability, as much as it

does that of tin. It becomes hard and rigid, and very difficult of fusion, and loses the appearance of lead; being, in the regulus thus obtained, composed of broad, bright, and glittering particles. Copper melts immediately upon being made red-hot, if brimstone be added to it; and becomes a black friable substance. Iron of all other metals melts the most freely and readily with the sulphur, but it does not freely part with it again. A red-hot iron applied to a roll of sulphur immediately throws off particles dissolved by the sulphur into a spongy scoria. Regulus of antimony melted with sulphur returns to common crude antimony again. Bismuth melted with it assumes the appearance of antimony, and instead of broad flakes is found to be composed of needles or striæ running across one another. Zink suffers less change from it, and mixes indeed less easily with it; it at length becomes darker coloured, and more brittle.

*Uses and Preparations of SULPHUR.* Besides the great use of sulphur in medicine, chemistry, metallurgy, and the making of gun powder, it is of great service for whitening of silks, and woollen stuffs; for which purpose, its vapour is contrived to be received by them: its vapour also whitens red roses; and even young rooks, taken out of their nests, and exposed thereto, become perfectly white: it has also the same effect upon gold, which may be restored to its colour, by boiling it in water with tartar: and, lastly, its fumes check and prevent fermentation; on which account, it is much used by wine-coopers.

As to the medical virtues of sulphur, it is given, in its crude state, with great success in diseases of the lungs. It strengthens and cleanses them, and promotes expectoration, and has at all times been famous for its virtues against cutaneous diseases. It generally proves a little loosening to the bowels, and increases the discharges by perspiration; it even communicates its smell to the perspired matter for a considerable time after taking it, and will often blacken gold or silver that is worn by people who take any considerable quantity of it.

The preparations of sulphur, in most frequent use in the shops, are, 1. Flowers of sulphur, *flores sulphuris*, a good pectoral medicine. See the article FLOS. 2. Precipitated sulphur, commonly called milk of sulphur, made by boiling flowers of sulphur, with thrice their weight of quick-lime, till the sulphur is dissolved; and then filtering the solution through paper, let a precipitation be made with weak spirit of vitriol; and lastly, by washing the precipitated powder found at the bottom of the vessel, till it becomes quite insipid. This is good in all uses, wherein sulphur in substance, or its flowers, are used; its dose being from ten grains to two scruples. 3. Balsam of sulphur is made by boiling flowers of sulphur in four times their weight of oil of olive, in a pot lightly covered, till the oil and sulphur

sulphur are united into the consistence of a balsam : and in the same manner may a balsam of sulphur be prepared with Barbadoes-tar. This, though highly extolled as a pectoral by some authors, ought to be given with great caution, since its acrimony must render it injurious to weak lungs. 4. Spirit or oil of sulphur is an acid, obtained by retaining in any manner the vapours of burning sulphur ; it is wholly the same with that of vitriol ; being an agreeable acid, and good in every case in which the spirit of vitriol is so. 5. Sulphurated water, *aqua sulphurata*, is made thus : take common water one quart, of pure sulphur half a pound, set a part of the sulphur on fire in an iron ladle, and suspend it in that state over the water in a close vessel ; let the remainder of the sulphur be afterwards fired and suspended in the same manner, and when the operation is over, the water will have acquired a sharp acid taste, and is to be reserved for use. The most commodious vessel for making this is a large glass receiver fitted with a wooden plug, into which the handle of the ladle may be fixed ; as soon as the sulphur is fired, the ladle is to be thrust so far into the receiver, that the plug may come to stop the aperture, and the covering the mouth over this with a wet cloth will be sufficient to keep in the fumes.

This is the liquor called by some authors *gas sulphuris* ; it is an agreeable acid, and is good in malignant and petechial fevers, given in the common drink. It quenches thirst, and cools the mouth and tongue.

SULPHUR-WORT, in botany, a name by which some call the hog's-fennel. See the article PEUCEDANUM.

SULTAN, or SOLDAN, a title of honour, given to the emperor of the Turks. The wife of a sultan is called sultana, and the favourite one haseki-sultana, i. e. the private sultana.

SUM, *Summa*, in mathematics, signifies the quantity that arises from the addition of two or more magnitudes, numbers, or quantities together. See ADDITION.

The sum of an equation is, when the absolute number being brought over to the other side of the equation, with a contrary sign, the whole becomes equal to 0 : thus, the sum of the equation  $x^3 - 12x^2 + 41x - 42 = 0$ , is  $x^3 - 12x^2 + 41x - 42 = 0$ .

SUMACH, *Rhus*, in botany. See the article RHUS.

Myrtle SUMACH, *Coriaria*, in botany. See the article CORIARIA.

SUMMARY, in matters of literature, the same with abridgment.

Summary, however, is often used for a table of contents, placed at the beginning of books, to shew the principal heads treated of therein.

SUMMATORIUS CALCULUS, in mathematics. See the article CALCULUS.

SUMMER, one of the seasons of the year, commencing in these northern regions on the day the sun enters Cancer, and ending when he quits Virgo. Or, more strictly and universally, the summer begins on the day when the sun's meridian distance from the zenith is the least ; and ends on the day, when his distance is a mean betwixt the greatest and smallest. The end of summer coincides with the beginning of winter.

SUMMER, in architecture, is a large stone, the first that is laid over columns and pilasters, in beginning to make a cross vault ; or it is the stone which, being laid over a piedroit or column, is hollowed to receive the first haunce of a platband.

SUMMER, in carpentry, is a large piece of timber which being supported on two stone piers or posts, serves as a lintel to a door, window, &c.

SUMMIT, the top or vertex of any body, or figure ; as of a triangle, cone, pyramid, &c.

SUMMITS of Flowers, the same with the antheræ, or apices.

SUMMONS, in law, a citing or calling a person to any court, to answer a complaint, or even to give in his evidence.

There must also be a summons in real actions, whereby the sheriff warns the party to appear at a day on the tenant's land ; also fourteen days before the return, proclamation is to be made thereof, in order that the grand cape may issue.

SUMMONS and SEVERANCE. See the article SEVERANCE.

SUMMUM BONUM, in ethics. See the articles GOOD and HAPPINESS.

SUN, *Sol*,  $\odot$ , in astronomy, the great luminary which enlightens the world, and by its presence, constitutes day.

The sun is the principal source of heat upon the earth's surface, and the confines of the earth and atmosphere : without this, says Dr. Shaw, all the bodies upon our globe would doubtless grow fixed, rigid and lifeless ; it being the solar heat that stirs within them, as the main spring of their actions ; causing all the operations in the animal, vegetable, and mineral kingdoms ; and hence also, the ocean and atmosphere continue in a fluid state.

Sir Isaac Newton, in his Optics, gives good reasons to suppose the sun and fixed stars to be great earths vehemently hot ; whose heat is conserved by the greatness of their bodies, and the mutual action and reaction between them and the light which they emit ; and whose parts are kept from fuming away, not only by their fixity, but also by the vast weight and density of the atmospheres incumbent on them, and every way strongly compressing them, and condensing the vapours and exhalations which arise from them. The light seems to be emitted from the sun and fixed stars (which probably are suns to other systems) much after the manner as iron,

iron; when heated to such a degree as to be just going into fusion, by the vibrating motion of its parts, emits, with force and violence, copious streams of liquid fire, all around. Great bodies must preserve their heat longest, and that, perhaps, in the proportion of their diameters. See the article *STAR*.

The sun, then, may be conceived to be a huge body of fire, whence all the planets receive their light; and by the emanation of whose rays and beams of light, the whole system of beings about us is illuminated and rendered visible.

By means of the solar spots it hath been discovered, that the sun revolves round his own axis, without moving (considerably) out of his place, in about twenty-five days. And that the axis of this motion is inclined to the ecliptic, in an angle of 87 degrees, 30 minutes, nearly. See the articles *MACULÆ* and *FACULÆ*.

The sun's apparent diameter being sensibly shorter in December than in June, as is plain and agreed from observation, the sun must be proportionably nearer to the earth in winter than in summer; in the former of which seasons will be the perihelion, in the latter the aphelion: and this is also confirmed by the earth's moving swifter in December than it does in June. For since, as Sir Isaac Newton has demonstrated, the earth always describes equal areas in equal times, whenever it moves swifter, it must needs be nearer to the sun. And, for this reason, there are about eight days more from the sun's vernal equinox to the autumnal, than from the autumnal to the vernal.

For the apparent annual motion round the earth, see the article *EARTH*.

If you divide 360 degrees (i. e. the whole ecliptic) by the quantity of the solar year, it will quote 59 minutes 8 seconds, &c. which therefore is the quantity of the sun's diurnal motion. And, if this 59 minutes 8 seconds be divided by 24, you have the sun's horary motion, which is 2 minutes 28 seconds; and, if you will divide this last by 60, you will have this motion in a minute, &c. And this way are the tables of the sun's mean motion, which you have in the books of astronomical calculations, constructed.

For eclipses of the sun, cycle of the sun, maculæ and faculæ of the sun, &c. see *ECLIPSE*, *CYCLE*, &c.

*SUN-DEW*, *Drosera*, in botany. See *DROSERA*.

*SUN-FLOWER*, in botany, the English name for the helianthus. See the article *HELIANTHUS*.

*Dwarf SUN-FLOWER*, *Rudbeckia*, in botany. See the article *RUDBECKIA*.

*SUNDAY*, or the *LORD'S-DAY*, a solemn festival observed by Christians on the first day of every week, in memory of our Saviour's resurrection.

This is the principal and most noted of the Christian festivals, and was observed with great veneration

in the ancient church, from the time of the apostles, who themselves are often said to have met on that day for divine service.

It is likewise called the sabbath-day, as being substituted in the room of the Jewish sabbath. See the article *SABBATH*.

The ancients retained the name Sunday, or *dies solis*, in compliance with the ordinary forms of speech, the first day of the week being so called by the Romans, because it was dedicated to the worship of the sun.

Besides that the most solemn parts of the Christian worship were always performed on Sundays, this day was distinguished by a peculiar reverence and respect expressed towards it in the observation of some special laws and customs. Among these, we may reckon, in the first place, those imperial laws which suspended all proceedings at law upon this day, excepting only such as were of absolute necessity, or eminent charity; such as the manumission of slaves, and the like. Neither was it only the business of the law, but all secular and servile employments were superseded upon this day, still excepting acts of necessity and mercy.

Another thing which the Christian laws took care of, to secure the honour and dignity of the Lord's day, was, that no ludicrous sports or games should be followed on this day; but all such recreations and refreshments, as tended to the preservation or conveniency of life, were allowed of; and therefore, Sunday was always a day of feasting, and it was not allowable to fast thereon, not even in Lent.

The great care and concern of the primitive Christians in the religious observation of the Lord's day, appears, First, from their constant attendance upon all the solemnities of public worship, from which nothing but sickness, imprisonment, banishment, or some great necessity could detain them.

Secondly, from their zeal in frequenting religious assemblies on this day, even in times of the hottest persecution, when they were often beset and seized in their meetings and congregations.

Thirdly, from their studious observations of their vigils, or nocturnal assemblies, that preceded the Lord's day.

Fourthly, from their eager attendance on sermons, in many places, twice upon this day, and their constant resorting to evening prayers, where there was no sermon.

Lastly, from the severe censures inflicted on those who violated the laws concerning the religious observation of this day, such persons being usually punished with excommunication; as appears from the apostolical constitutions, and the canons of several councils.

In the Romish breviary, and other offices, we meet with a distinction of Sundays, into those of the first

first and second class: Sundays of the first class, are, Palm-Sunday, Easter-Sunday, Advent-Sunday, Whit-Sunday, &c. those of the second class are the common Sundays of the year.

By our laws, no person is to do any worldly labour on this day, which is set apart for the service of God, except works of necessity and charity, under the penalty of five shillings. And if any person cry, or expose to sale, any wares or goods on a Sunday, the same will be forfeited to the poor, &c. the offender being convicted thereof before a justice of the peace, who is authorised to cause the penalties and forfeitures to be levied by distress. Yet this extends not to dressing of meat, nor to the crying or selling of milk in the morning or evening, or the selling of mackerel on that day.

The Sunday is not a day in law, so that no process lies, or may be served thereon, except for treason, or felony, or an escape. A sale of goods, or contract made on a Sunday, is deemed void.

**SUNDAY-LETTER.** See the article **DOMINICAL-LETTER**.

**SUPERCARGO**, a person employed by merchants to go a voyage, and oversee their cargo, or lading, and dispose of it to the best advantage. See the articles **CARGO**, **FACTOR**, &c.

**SUPERCILIUM**, in anatomy, the eye-brow. See the article **EYE-BROW**.

**SUPERCILIUM**, in the ancient architecture, the uppermost member of the cornice, called by the moderns corona, crown, or larmier.

**SUPEREROGATION**, in theology, what a man does beyond his duty, or more than he was commanded to do. The Romanists stand up strenuously for works of supererogation, and maintain, that the observance of evangelical councils is such. By means hereof, a stock of merit is laid up, which the church has the disposal of, and which she distributes in indulgences to such as need. The reformed church do not allow of any work of supererogation.

**SUPERFETATION**, *Superfœtatio*, in medicine, a second, or after conception, happening, when the mother, already pregnant, conceives of a later coition; so that she bears at once two fœtuses of unequal age and bulk, and is delivered of them at different times.

**SUPERFICIES**, or **SURFACE**, in geometry, a magnitude considered as having two dimensions; or extended in length and breadth, but without thickness or depth. In bodies, the superficies is all that presents itself to the eye. A superficies is chiefly considered as the external part of a solid. When we speak of a surface simply, and without any regard to body, we usually call it figure. The several kinds of superficies are as follow. Rectilinear superficies, that comprehended between right lines; curvilinear superficies, that comprehended between curve lines; plane superficies, is that which has no

inequality; but lies evenly between its boundary lines; convex superficies, is the exterior part of a spherical, or spheroidal body; and a concave superficies, is the internal part of an orbicular or spheroidal body.

The measure or quantity of a superficies, or surface, is called the area thereof.

The finding of this measure, or area, is called the quadrature thereof.

To measure the surfaces of the several kinds of bodies, as spheres, cubes, parallelepipeds, pyramids, prisms, cones, &c. see the article **SPHERE**, &c.

**Line of SUPERFICIES**, a line usually found on the sector, and Gunter's scale, the description and use whereof, see under **SECTOR** and **GUNTER'S SCALE**.

**SUPERFINE**, in the manufactories, a term used to express the superlative fineness of a stuff; thus a cloth, a camblet, &c. are said to be superfine, when made of the finest wool, &c. or when they are the finest that can be made. The term is particularly used among gold or silver wire-drawers, for the gold or silver wire, which after being drawn through an infinite number of holes, each less and less, is at length brought to be no bigger than an hair.

**SUPERINSTITUTION**, *Superinstitutio*, denotes an institution upon another, as where A B is admitted and instituted to a benefice upon one title, and C D is admitted and instituted on that of another.

**SUPERINTENDANT**, in the French customs, an officer who has the prime management and direction of the finances or revenues of the king. The term is also used for the first officer of the queen's household, who has the chief administration thereof. They have also a superintendent of the buildings, answering to the surveyor of the works among us.

**SUPERINTENDANT** also denotes an ecclesiastical superior in several reformed churches, where episcopacy is not admitted, particularly among the Lutherans in Germany, and the Calvinists in some other places. The superintendent is in effect little other than a bishop, only his power is somewhat more restrained than that of the diocesan bishops. He is the chief pastor, and has the direction of all the inferior pastors within his district or diocese.

**SUPERIOR**, or **SUPERIOUR**, something raised above another, or that has a right to command another.

**SUPERJURARE**, was anciently a term used in our law where a criminal endeavoured to excuse himself by his own oath, or by the oath of one or two witnesses; and the crime charged against him so notorious, that he was convicted upon the oaths of many more witnesses; this was termed superjurare.

**SUPERLATIVE**, in grammar, one of the three degrees of comparison, being that inflection of nouns-adjective that serves to augment and heighten their signification, and shews the quality of the thing denoted to be in the highest degree.

In English, the superlative is usually formed by the addition of *est* to the positive, as *richest*, *greatest*, &c. and frequently by prefixing of *most*, as *most rich*, *most great*, &c.

**SUPERNUMERARY**, something over and above a fixed number. In several of the offices are supernumerary clerks, to be ready on extraordinary occasions. There are also supernumerary surveyors of the excise, to be ready to supply vacancies when they fall; these have but half pay. In music, the supernumerary, called by the Greeks *proslambanomenos*, is the lowest of the chords of their system, answering to *a*, *mi*, *la*, of the lowest octave of the moderns.

**SUPERONERATIONE PASTURÆ**, in law, a judicial writ which lies against a person that is impleaded in the county-court, for surcharging of a common with his cattle, in a case where he was formerly impleaded for it in the same court, and the cause is removed to one of the courts of Westminster.

**SUPER-PURGATION**, *Hypercatarrasis*, in medicine, an excessive over-violent purging, the usual effects of colliquating, corrosive and stimulating medicines. In the beginning of this disorder, a very thin matter is evacuated: but afterwards, when the relaxation and aperture of the vessels are increased, the necessary humours are discharged; there is first an excretion of yellow bile, then of phlegm, then of black bile, and last of all blood. See the article **FLUX**.

Those who labour under a superpurgation, must be treated with frictions of the skin, and a warm bath; drinking, before they bathe, thin, red, or yellow wine, for such is easiest of distribution, with fops of bread, and pomegranates.

If the evacuation continues, let the limbs be bound in such a manner, that the bandage may be carried from the upper to the lower parts. Exhibit also a small quantity of theriaca, to be taken with the flesh of vipers, or, for want of that, troches of theriaca, or troches of seeds, and of the antidote called philonium. Cupping-glasses may also be applied to the stomach, and cataplasms of polenta and mulsam; after which, you may use astringent epithems, but the greatest relief is had from frictions of the whole body, and potable remedies. The patient should keep himself from cold air, or what is very warm. If the evacuation still continues, the aforesaid cataplasms should be applied, and obtundents injected in clysters, such as the fat of geese, sweet wine, oil of spike, and the like.

**SUPERQUADRIPARTIENS**. See the article **RATIO**.

**SUPERSCAPULARIS INFERIOR**, in anatomy, the same with *infraspinatus*. See the article **INFRA-SPINATUS**.

**SUPERSCAPULARIS SUPERIOR**, is the same with *supraspinatus*. See the article **SUPRASPINATUS**.

**SUPERSEDEAS**, in law, according to Fitzherbert, is a writ which lies in divers cases, and in general signifies a command to stay some of the ordinary proceedings in law, which, on good cause shewn, ought not to proceed. It is likewise used for staying of an execution after a writ of error is allowed, and bail put in, but not before bail is given, in case there be a judgment upon verdict, or by default in debt, &c.

A supersedeas is also granted by the court for setting aside an erroneous judicial process, &c. And a prisoner may be thereby discharged upon entering his appearance, and on the plaintiff's not filing a declaration against him. For this writ is as good a cause to discharge the person, as the first process is to arrest him. There is a further writ of supersedeas, where an audita querela is sued, and in cases of surety of the peace, when one is already bound to the peace in chancery, or elsewhere.

**SUPER-STATUTO DE ARTICULIS CLERI**, in law, a writ that lies against the sheriff, or other officer, that distrains in the king's highway, or in the lands anciently given to the church.

**SUPER-STATUTO FACTO POUR SENESCHAL ET MARSHAL DE ROY**, &c. a writ which lies against the steward or marshal, for holding plea of freehold in his court, or for trespass, or contracts not made within the king's household.

**SUPER-STATUTO VERSUS SERVANTES ET LABORATOIRES**, a writ lying against a person who keeps another person's servant departed from his service, contrary to law.

**SUPERSTITION**, extravagant devotion, or religion, wrong directed, or conducted.

**SUPERVISOR**, a surveyor or overseer.

It was formerly, and still remains a custom among some persons, to appoint a supervisor of a will, to see that the executors thereof do punctually observe and perform the same.

Supervisor formerly was used for surveyor of the highways. There are likewise certain officers of the excise, who are called supervisors, on account of their having the supervising and inspecting of the books, &c. of the inferior officers belonging to that branch of the revenue, to prevent their neglect of duty.

**SUPINATION**, in anatomy, the action of a supinator-muscle, or the motion whereby it turns the hand so as that the palm is lifted up towards heaven.

**SUPINATOR**, in anatomy, a denomination given to two muscles of the arm, the one called

the supinator longus, the other the supinator brevis, both serving to turn the palm of the hand upwards. The first has its origin from the exterior spine of the humerus, and its termination at the lower end of the radius; the second rises from the upper part of the ulna, and is inserted into the upper part of the radius, which it totally surrounds and incloses. This last muscle may also be of use in the bending of the cubit.

**SUPINE**, in Latin grammar, part of the conjugation of a verb, being a verbal substantive of the singular number, and the fourth declension.

There are two kinds of supines; one, called the first supine, ending in *um*, of the accusative case, is always of an active signification, and marks a motion, as *abii deambulum*; the other, called the last supine, and ending in *u*, of the ablative case, is of a passive signification, and is governed by substantives or adjectives, as *facile dictu*, &c.

**SUPPLE**, to supple a horse in the manege, is to make him bend his neck, shoulders, and sides, and to render all the parts of his body more pliable.

**SUPPLEMENT** of an Arch, in geometry, or trigonometry, is the number of degrees that it wants of being an intire semicircle; as a complement, signifies what an arch wants of being a quadrant.

**SUPPLEMENT**, in matters of literature, an appendage to a book, to supply what is wanting therein.

**SUPPLICAVIT**, in law, a writ that issues out of the court of Chancery for taking surety of the peace, where a person is in danger of receiving some bodily hurt from another. It is directed to the justices of the peace and sheriff of the county, and is grounded on the statute 1 Edw. III. which appoints, that certain persons shall be appointed by the lord-chancellor to take care of the peace. In order to sue out this writ, the party requiring it first goes before one of the masters in Chancery and makes oath, that he does not desire the same out of any malice, but purely for his own safety, and the security of his person; upon which the master will make out a warrant, ordering the writ to be made out by one of the clerks of the six clerk's office, after which the writ must be delivered to the sheriff to have his warrant thereon for arresting the party, &c.

**SUPPORTED**, in heraldry, a term applied to the uppermost quarters of a shield when divided into several quarters, these seeming as it were supported or sustained by those below. The chief is said to be supported when it is of two colours, and the upper colour takes up two thirds of it. In this case it is supported by the colour underneath.

**SUPPORTERS**, in heraldry, figures in an achievement placed by the side of the shield, and seeming to support or hold up the same. Supporters are chiefly figures of beasts: figures of human crea-

tures, for the like purpose, are properly called tenants. Some make another difference between tenant and supporter: when the shield is borne by a single animal, it is called tenant; when by two, they are called supporters. The figures of things inanimate sometimes placed aside of escutcheons, but not touching or seeming to bear them, though sometimes called supporters, are more properly cotises.

The supporters of the British arms are a lion and an unicorn: those of the French arms are angels &c. See ARMS.

In England, none under the degree of a banneret are allowed supporters, which are restrained to those called the high nobility. The Germans permit none but princes and noblemen of rank to bear them: but among the French the use of them is more promiscuous.

**SUPPOSITION**, in music, the using two successive notes of equal value as to time, one of which, being a discord, supposes the other a concord.

The harmony, Mr. Malcolm observes, is to be always full on the accented part of the measure or bar, and void of discords; yet here discords, by proper resolution and preparation, are even necessary on the accented part of the measure. Discords, by conjoint degrees, may pass without much offence, and it is not there required that the harmony be so complete as on the accented part. This transient use of discords, followed by concords, makes what the French call supposition. There are several kinds of supposition. The first is when the principal parts proceed gradually from concord to discord, and from discord to concord; the intervening discord serving only as a transition to the following concord. Another kind is when the parts do not proceed gradually from discord to concord, but descend to it by the interval of a third. A third kind, like the second, is when the rising to the discord is gradual, but the descending from it to the following concord, is by the distance of a fourth. A fourth kind, very different from all the rest, is when the discord falls on the accented part of the measure, and the rising to it is by the interval of a fourth; in which case it is absolutely necessary to follow it immediately by a gradual descent into a concord that has just been heard before the harmony to make the preceding discord pass without offence, and only seem a transition to the concord.

**SUPPOSITORY**, *Suppositorium*, in pharmacy, a kind of medicated cone, or ball, which is introduced to the anus, for opening the belly.

Suppositories are usually made of soap, sugar, alum, or a piece of tallow-candle, about the length of a man's thumb and the breadth of a finger, tho' they may be made smaller for children, and sometimes a little thicker for adults.

Suppositories are sometimes compounded of ingredients

gredients adapted to the disease and circumstances of the patient, as of honey, salt, powder of aloes, colocynthis, and the like. If one suppository does not occasion a stool, it must be followed by another stronger one; and if that does not succeed, the repetition must be continued till the effect required is produced. They are sometimes lubricated with oil or butter, that they may be introduced with greater ease. Some use a lozenge of sugar, or a piece of thin linen cloth, rolled up with a little lard or salt-butter, which greatly loosens the belly.

For ulcers of the rectum, the best suppositories are made of honey of roses, powder of mastic and myrrh, or of colophony.

The stronger suppositories, which are composed of acrid and stimulating ingredients, are advantageously used in promoting a difficult birth, if the infant be in a natural position; and also for expelling the secundines, when they are tenaciously retained in the uterus.

In exhibiting them, the patient should be put in the same posture as in giving a clyster, and the suppository must be gently thrust up the anus with the finger.

**SUPPRESSION**, in law, the extinction or annihilation of an office, right, rent, or the like.

**SUPPRESSION**, in grammar and rhetoric, denotes an omission of certain words in a sentence, which yet are necessary to full and perfect construction: as, "I came from my father's;" that is, "from my father's house."

Suppression is a figure of speech very frequent in our language, chiefly used for brevity and elegance. Some rules relating hereto are as follow: 1. Whenever a word comes to be repeated in a sentence oftener than once, it is to be suppressed: thus we say, "This is my master's horse;" not "This horse is my master's horse." 2. Words that are necessarily supplied may be suppressed. 3. All words that use and custom suppress in other languages, are also to be suppressed in English, unless there be particular reasons for the contrary.

Suppression is also a figure in speech, whereby a person in rage, or other disturbance of mind, speaks not out all he means, but suddenly breaks off his discourse: thus, the gentleman in Terence, extremely incensed against his adversary, accosts him with this abrupt saying, "Thou of all." The excess of his indignation and rage choked the passage of his voice, and would not suffer him to utter the rest. But in these cases, though the discourse is not complete, the meaning is readily understood, and the evidence of the thought easily supplies the defect of words.

Suppression, sometimes, proceeds from modesty, and fear of uttering any word of ill and offensive sound.

**SUPPRESSION**, in medicine, is generally used for

a retention of urine or the menses. See the articles **DYSURY**, **ISCHURY**, **MENSES**, &c.

**SUPPRESSIONIS IGNIS**, a fire of suppression, a term used, in chemistry, to express such an application of fire to any subject that it shall at once act upon it, both above and below, in the same manner.

The usual way of giving this heat is by covering the vessel, in which the ingredients are put, with sand, and then laying hot coals upon that, so that they may heat through the sand downwards.

**SUPPURATION**, in medicine and surgery, the second way wherein an inflammation terminates, being a conversion of the inspissated blood and the soft adjacent parts, as the vessels and fat, into pus, or matter: which disorder, when it has not yet found an opening, is generally called an abscess.

The best cure of an inflammation is by resolution or dispersion: but when this is out of the power of the surgeon or physician to effect, and when tumours and phlegmons shew a tendency to suppuration, all the resolving and dispersing medicines must be laid aside, and great care must be taken to forward the maturity of the inflammation; that is, to convert the stagnated blood into laudable matter; then to give a discharge, or vent, to this suppurated matter; afterwards to cleanse the part; and finally to incarnate and heal it.

In general, suppuration is to be promoted by such of the emollient medicines as obstruct the pores of the skin, as fat, oils, and glutinous medicines; as also the sharp, pungent, and in some degree, caustic medicines, which may be used in form of cataplasms or plasters. But to be more particular, suppurating medicines, besides those already enumerated under abscesses, &c. are the fats of a goose, of a dog, of a man, of a viper, and of a bear; pigeon and cow dung; bran, yeast, herrings, leeches, melilot, tobacco, oil, Burgundy-pitch, common-pitch, rosin, deer-suet, ox-suet, sheep-suet, and frankincense. These medicines, either alone or compounded, are to be applied hot to the part, and the application frequently repeated, till the matter within is found to be sufficiently ripened by the softness and whiteness of the tumour: but when the abscess is small, it is sufficient and more convenient to apply some of the ripening plasters, as diachylon, with the gums, or the like, till the suppuration is perfected.

A ripening cataplasm from the London dispensatory, is as follows: Take of figs, four ounces; yellow basilicum ointment, one ounce; galbanum strained, half an ounce: beat the figs thoroughly in a mortar, occasionally dropping in some spirit of wine, or strong ale; then carefully mix them with the ointment first liquified along with the galbanum. And a ripening plaster from the Edinburgh dispensatory is this: Take of gum-plaster, an ounce and a half;

half; Burgundy-pitch, half an ounce: boil them together.

In general, it is to be observed, that suppurative medicines are such as by the activity and warmth of their parts, are able to penetrate the pores, and mix with and rarify any obstructed matter, so that it may be rendered fit to discharge, upon laying open the part by a caustic or incision.

Now, in many instances, as the matter by this means rarifies and grows more fluid, the reflux blood is apt to wash it back into the common mass, which sometimes is of that nature as to do a great deal of mischief; or by making it take up more room upon its rarefaction, occasions it more to distend the parts in which it is contained, whereon a sense of pain is excited, and thereby a greater course of fluid, and consequently a needless increase of the tumour; so that medicines under this denomination, require to be in the hand of such as are so well acquainted with the mechanism of the animal economy, as to be able to apply them to the best advantage, and know how to avoid the hazards which may arise from their abuse. Nor are internal remedies to be neglected, in order to further a suppuration, especially when the tumour is large and of consequence.

In these cases, when the blood moves too slowly, which may be known by the pulse, the patient must be allowed to eat meat, and must take such medicines as are warm and stimulating, by means of which, and by the increased motion of the blood, the inspissated particles contained in the smaller vessels, will be the more easily converted in matter.

Strong broths are very proper for this purpose, as also the use of wine, or ale, in moderation; and Venice-treacle, diascordium, and the confection of alkermes, are to be the medicines taken three or four times a day, and medicated teas, made of saunders-wood, saffrafs, or cinnamon.

But on the contrary, when the motion of the blood is too violent, and the heat too great, cooling medicines are to be given, such as the thin and watery drinks, the sub-acid medicines, and nitre: bleeding, in a small quantity, is also often necessary in this case.

But when the constitution is sound, and the blood's motion regular, the use of internal medicines, to promote suppuration, is trifling, and may be altogether rejected. See the articles ABSCESS, TUMOUR, WOUND, &c.

SUPPURATIVES, or suppurating medicines, such as promote suppuration. See the preceding article.

SUPPUTATION. See the article COMPUTATION.

SUPRACOSTALES, or *Levatores Costarum*, in anatomy, muscles serving to respiration; being among those that dilate the thorax for that end, and

therefore reckoned among the dilatores. See the article DILATORES.

These muscles are of two kinds, being distinguished from their figures into short and long.

The short ones are twelve on each side; they have their origin from the transverse processes of eleven vertebræ of the back, and of one that is in the lower one of the neck, and they are inserted into the hinder part of the ribs.

The long supracoastales are three or four; their origin is the same with the seventh, eighth, ninth, and tenth vertebræ, and their end in the ninth, tenth, eleventh, and twelfth ribs.

SUPRALAPSARY, in theology, a person who holds that God, without any regard to the good or evil works of men, has resolved, by an eternal decree, to save some and damn others. These are also called antelapsaries, and are opposed to sublapsaries and infralapsaries.

SUPRASPINATUS, in anatomy, a muscle thus called from its fleshy origination at the upper end of the basis of the scapula above the spine, to the upper part whereof it is connected, as also to the superior edge of the scapula, whence marching along the upper interscapulum, or thin part of the scapula, which it fills, it passes under the acromium and articulation of the humerus. It helps to lift the arm upwards.

SUPREMACY, in our polity, the superiority or sovereignty of the king over the church as well as state, whereof he is established head. See the article KING.

The king's supremacy was at first established, or, as others say, recovered, by king Henry VIII. in 1534, after breaking with the pope. It is since confirmed by several canons, as well as by the articles of the church, and is passed into an oath which is required as a necessary qualification for all offices and employments both in church and state, from persons to be ordained, from the members of both houses of parliament, &c.

SURA, in anatomy, the calf, or fleshy part of the leg. The word is also used by some for the fibula, which see.

SURBATING, among farriers, is when the sole of a horse's foot is worn, bruised, or spoiled by beating the hoof against the ground in travelling without shoes, or going in hot sandy lands, or with a shoe that hurts the sole, lies too flat to it, or the like. Sometimes it also happens by over-riding a horse while young, before his feet are hardened; and sometimes by the hardness of the ground and high lifting his feet. The signs hereof are his halting on both fore-legs, and going stiffly, and creeping as if half foundered.

In the general, there is nothing better for surbated feet, than tar melted into the foot, or vinegar boiled with foot to the consistence of a broth, and put

put into the foot boiling hot, with hürds over it, and splints to keep it in.

**SURCHARGE**, the same with overcharge, and whatever is above that which is just and right.

Surcharge of the forest, or a common, is when a commoner puts more beaſts in the forest, or common, than he has a right to do.

**SURCINGLE**, a girdle wherewith the clergy of the church of England usually tie their cassock.

**SURCOAT**, a coat of arms to be worn over the body armour.

The surcoat is properly a loose thin taffety-coat, with arms embroidered or painted on it, such as is worn by heralds: anciently also used by military men, over their armour, to distinguish themselves by.

**SURCULUS**, in the anatomy of plants, a word used to express that part of the branching of the ribs of a leaf, which is of a middle kind betwixt the great middle rib and the smallest reticular ramifications.

The middle rib is, by the writers on these subjects, called petiolum. The first division that go off laterally from these are called rami, or branches; the next division of these into more minute ones, furculi; and the final divarications of these, into the reticular work that spreads itself over the whole leaf, capillamenta. See PETIOLUM, &c.

**SURD**, in arithmetic and algebra, denotes any number or quantity that is incommensurable to unity: otherwise called an irrational number or quantity.

The square roots of all numbers, except 1, 4, 9, 16, 25, 36, 49, 64, 81, 100, 121, 144, &c. (which are the squares of the integer numbers, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, &c.) are incommensurables; and after the same manner the cube roots of all numbers but of the cubes of 1, 2, 3, 4, 5, 6, &c. are incommensurables: and quantities that are to one another in the proportion of such numbers, must also have their square-roots, or cube-roots, incommensurable.

The roots, therefore, of such numbers, being incommensurable, are expressed by placing the proper radical sign over them: thus,  $\sqrt[3]{2}$ ,  $\sqrt[3]{3}$ ,  $\sqrt[3]{5}$ ,  $\sqrt[3]{6}$ , &c. express numbers incommensurable with unity. However, though these numbers are incommensurable themselves with unity, yet they are commensurable in power with it; because their powers are integers, that is, multiples of unity.

They may also be commensurable sometimes with one another, as the  $\sqrt[3]{8}$  and  $\sqrt[3]{2}$ ; because they are to one another as 2 to 1: and when they have a common measure, as  $\sqrt[3]{2}$  is the common measure of both, then their ratio is reduced to an expression in the least terms, as that of commensurable quantities, by dividing them by their greatest common measure. This common measure is found as in

commensurable quantities, only the root of the common measure is to be made their common divisor:

thus,  $\frac{\sqrt[3]{12}}{\sqrt[3]{3}} = \sqrt[3]{4} = 2$ , and  $\frac{\sqrt[3]{18a}}{\sqrt[3]{2}} = 3\sqrt[3]{a}$ .

**SURDESOLID**, or **SURSOLID**. See the article **SURSOLID**.

**SURETY**, in law, generally signifies the same with bail. See **BAIL**.

**SURFEIT**, in medicine, a sickness proceeding from the sensation of a load at the stomach, usually attended with eruptions, and sometimes with a fever.

**SURGE**, in the sea language, the same with a wave. See **WAVE**.

Also when heaving at the capstan, if the cable royal, or messenger slip a little, they call it surging.

**SURGERY**, or **CHIRURGERY**, χειρουργία, the art of curing all manner of wounds, and other disorders, where the application of the hand, assisted by proper instruments, is necessary.

**SURIANA**, in botany, a genus of plants, whose flower consists of five oval patent petals the length of the cup, with five slender stamina, and the same number of germina, which become five roundish seed joined together.

**SURMOUNTED**, in heraldry, is when one figure is laid over another.

**SURNAME**, or **SIRNAME**, a name added to the proper or baptismal name, to denote the person of such a family.

**SURREJOINDER**, is a second defence of the plaintiff's declaration, by way of answer to the defendant's rejoinder.

**SURRENDER**, in common law, an instrument in writing, testifying, that the particular tenant of lands and tenements for life or years, doth sufficiently consent and agree, that he who has the next or immediate remainder or reversion thereof, shall have the present estate of the same in possession, and that he thereby yields and gives up the same to him.

**SURROGATE**, in law, denotes a person that is substituted, or appointed, in the room of another, and most commonly of a bishop, or of his chancellor.

**SURSOLID**, or **SURDESOLID**, in arithmetic and algebra, the fifth power, or fourth multiplication of any number or quantity considered as a root. See **ROOT**.

**SURVEY**, in law, is the ascertaining not only the boundaries and royalties of a manor, or estate in lands; but also the tenure of the respective tenants, and the rent and value of the same.

**SURVEYOR**, a person who hath the oversight and care of considerable works, lands, or the like.

**SURVEYOR** likewise denotes a gauger; as also a person who surveys lands, and makes maps of them.

**SURVIVOR**, in law, signifies the longest liver of joint-tenants, or of any two persons, jointly interested in a thing; in which case, if there be only two joint-tenants, upon the death of one, the whole goes to the survivor: and if there be more than two, the part of the deceased is divided among all the survivors.

**SUSPENSION**, or *Points of SUSPENSION*, in mechanics, are those points in the axis or beam of a balance, wherein the weights are applied, or from which they are suspended.

**SUSPENSION of Arms**, in war, a short truce agreed on by both armies, in order to bury the dead, wait for fresh instructions, or the like.

**SUTURE**, *Sutura*, in anatomy, a kind of articulation peculiar to the cranium, or skull. See **SKULL**.

**SUTURE**, in surgery, a method of uniting the lips of wounds. See **WOUND**.

**SWABBER**, an inferior officer on board ships of war, whose employment it is to see that the decks are kept clean.

**SWALLOW-TAIL**, in fortification, the same with queue d'aronde. See **QUEUE**.

**SWALLOW'S-TAIL**, in carpentry and joinery. See **DOVE-TAILING**.

**SWALLOW-WORT**, *Asclepias*, in botany. See **ASCLEPIAS**.

**SWAN**, *Cygnus*, in ornithology. See the article **CYGNUS**.

**SWARDY**, in agriculture, an appellation given to lands well covered with grass.

**SWATH**, *Fascia*, in surgery, a long and broad bandage, for binding up any disordered limb.

**SWEAT**, *Sudor*, a sensible moisture issuing out of the pores of the skin of animals. See the article **PERSPIRATION**.

**SWEATING SICKNESS**. See the article **SUDOR ANGLICANUS**.

**SWEET**, in the wine trade, denotes any vegetable juice, whether obtained by means of sugar, raisins, or other foreign or domestic fruit, which is added to wines, with a design to improve them. See the article **WINE**.

**SWEET-ALMONDS**. See **ALMONDS**.

**SWEET-GUM**. See **LIQUID AMBER**.

**SWEET-WILLIAM**, in botany, the English name of a very beautiful species of dianthus. See **DIANTHUS**.

Sweet-Williams are propagated by seeds or slips; those which are raised from seeds are best, not only for blowing stronger, but also for producing new varieties. The season for sowing it is in March; and when the plants are up two or three inches, they should be planted out in beds at seven or eight inches asunder; here they may remain till autumn, when they should be transplanted where it is intended for them to blow, which will be in the succeeding summer.

**SWERTIA**, in botany, a genus of plants, whose flower consists of a single petal, with a plane limb divided into five lanceolated segments, and ten nectaria; the stamina are five subulated filaments, terminated with incumbent antheræ: the fruit is a cylindrical capsule pointed at each end, formed of two valves and one cell, which contains many small seeds.

**SWIETENIA**, in botany, a genus of plants, whose flower consists of five concave, obtuse, patent petals, with a cylindric nectarium the length of the petals, and cut at its mouth into ten indentures; the stamina are ten very minute filaments, topped with oblong erect antheræ: the fruit is a large, woody, ovate capsule, having five cells, and opening at the base with five valves; the seeds are numerous, imbricated, compressed, oblong, and obtuse.

**SWIFTERS**, in a ship, are ropes belonging to the fore and main shrouds, for securing those masts.

**SWIMMING**, the art or act of sustaining the body in water, and of moving therein; in which action the air-bladder and fins of fishes bear a considerable part.

**SWINGLING**, the beating of flax, or hemp, after it has been well broken with the brake; this is done by taking up the flax in handfuls, and then beating it with a rod, or flatted and smooth stick, in order to free it from the bun, and prepare it for being heckled. See the articles **FLAX** and **HEMP**.

**SYCAMORE-TREE**, in botany, the English name of the acer major, or greater maple. See the article **MAPLE**.

**SYLLABLE**, *συλλαβη*, in grammar, a part of a word, consisting of one or more letters, pronounced together. See the articles **WORD** and **PRONUNCIATION**.

**SYLLABUS**, in matters of literature, denotes a table of contents, or an index of the chief heads of a book or discourse.

**SYLLEPSIS**, in Latin and Greek grammar, is the agreement of a verb or adjective, not with the word next it, but with the word most worthy in the sentence.

**SYLLOGISM**, *συλλογισμος*, in logic, an argument or term of reasoning, consisting of three propositions; the two first of which are called premises, and the last the conclusion. See the articles **REASONING**, **PROPOSITION**, &c.

**SYMBOL**, *συμβολον*, a sign or representation of something moral, by the figures or properties of natural things.

**SYMMETRY**, *συμμετρια*, the just proportion of the several parts of any thing, so as to compose a beautiful whole.

**SYMPATHETIC**, something that acts, or is acted on, by sympathy: thus we say, sympathetic diseases, inks, powders, &c. See the article **DISEASE**, &c.

**SYMPATHY**, *συμπαθεια*, an agreement of affections and inclinations, or a conformity of natural qualities, humours, temperaments, &c. which make two persons delighted and pleased with each other.

**SYMPHONY**, *συμφωνια*, in music, properly denotes a consonance or concert of several sounds agreeable to the ear, whether vocal or instrumental, called also harmony. See the articles **HARMONY** and **CONCERT**.

**SYMPHYSIS**, in anatomy, one of the kinds of junctures, or articulations of the bones. See **ARTICULATION**.

**SYMPHYTUM**, comfrey, in botany, a genus of plants, whose flower is monopetalous and campanulated; the tube is very short, and the limb is ventricosely tubulated, with the mouth cut into five segments, which are reflexed and obtuse: there is no pericarpium, but the cup contains four gibbous acuminate seeds, which join together at their tops.

The greater comfrey, called *consolida major*, grows wild in divers parts of England: this has a thick fleshy root, divided into several parts, black without, but white and clammy within: the lower leaves are hairy, large, sharp pointed, and of a dark green colour: the stalk rises to about two feet high, and are light, hairy, rough, and winged; these are terminated by loose bunches of flowers, of a whitish colour, and blow in July.

The root of comfrey has the same qualities as marsh-mallow; it is recommended in ulcers of the lungs, and other disorders that proceed from the acrimony of the humours: outwardly, it is said to cure wounds, but is now seldom or never used for that purpose.

**SYMPTOM**, *συμπτωμα*, in medicine, any appearance in a disease, which serves to indicate or point out its cause, approach, duration, event, &c. See **DISEASE**, &c.

**SYMPTOMATICAL**, in medicine, is a term often used to denote the difference between the primary and secondary causes in diseases.

**SYNÆRESIS**, *συναίρεσις*, contraction in grammar, a figure whereby two syllables are united as one; as *vehemens*, for *vehemens*.

**SYNAGOGUE**, *Synagoga*, a particular assembly of Jews, met to perform the offices of their religion. Also the place wherein they meet.

**SYNARTHROSIS**, in anatomy, a species of articulation, wherein there is only an obscure motion, as in the bones of the carpus and metacarpus, the tarsus and metatarsus, &c. or there is no motion at all, as in the sutures of the skull, and articulations per harmoniam, or bare application. See **CARPUS**, &c.

**SYNCOPE FAINTING**, in medicine, a deep and sudden swooning, wherein the patient continues without sensible heat, motion, sense, or respiration, and is seized with a cold sweat over the

whole body, and all the parts turn pale and cold as if dead.

**SYNGENESIA**, from *συν*, together, and *γενεσις*, generation, the name of the nineteenth class in the Linnæan System of Botany; so called because the antheræ (which are the part more immediately subservient to generation) are in this class united in a cylinder, and perform their office together.

This class consists of such plants as bear compound flowers; the general characters are, the common cup is a perianthium, which contains the florets and the receptacle; it is either simple, augmented, or imbricated; it contracts when the flowers are fallen, but expands and turns back when the seeds are ripe.

The common receptacle of the fructification receives many sessile florets on its disc, and is of different forms. Some of the flowers in this class are,  
1. Composed of tubulose hermaphrodite florets in the disc, and of the same sort in the radius.

2. Others are composed of tubulose hermaphrodite florets in the disc, and of tubulose female florets in the radius.

3. Some are composed of tubulose hermaphrodite florets in the disc, and of tubulose neutral florets in the radius.

4. Some have tubulose hermaphrodite florets in the disc, and ligulated hermaphrodite florets in the radius.

5. Some are composed of tubulose hermaphrodite florets in the disc, and of ligulated female florets in the radius.

6. Some are composed of tubulose hermaphrodite florets in the disc, and ligulated neutral ones in the radius.

7. Some are composed of tubulose hermaphrodite florets in the disc, and of naked and neutral florets in the radius.

8. Some are composed of tubulose male florets in the disc, and of naked female ones in the radius.

And, 9. Some are composed of ligulated female florets in the disc, and ligulated hermaphrodite ones in the radius.

The corollulæ are monopetalous and seated on the germina, and are either tubulated, ligulated, or tridentated: the stamina are five very short filaments, inserted in the neck of the corollulæ; the antheræ are of the same number, and are linear, erect, and grow together at their sides, so as to form a tubulate cylindric body the length of the limb, and quinque-dentated at the edge: the germen is oblong, and placed under the receptacle of the flower: the style is slender, erect, the length of the stamina, and perforates the cylinder formed by the antheræ: the stigma is divided into two parts, which stand open and bend backwards: there is no true pericarpium: the seed is single, oblong, often tetragonal, but commonly narrow at the base.

In some genera they are crowned with down, but in

in others it is wanting; in some the downy matter is composed of a great number of single short threads placed circularly or otherwise; on the head of the seed, in some, the down is radiated, in others ramose or branched, and in some it is supported on a pedicle, while in others it stands immediately on the seed. In some genera the seeds have no down at all, but have a small corona formed of what was originally the cup of the corollulæ, this is permanent, and divided usually into five segments.

In some genera the seed is wholly naked, having neither down or cup.

The genera of this class are very numerous, most of which are bitter and stomachic.

**SYNTAX**, *συνταξις*, in grammar, the proper construction, or due disposition of the words of a language, into sentences, or phrases.

**SYNTHESIS**, in logic, denotes a branch of method opposite to analysis, called the synthetic method. See **METHOD**.

**SYRINGA**, the lilac, in botany, a genus of plants, whose flower is monopetalous and funnel-shaped; the tube of the corolla is cylindric and very long, and the limb is divided into four obtuse plane segments; the stamina are two very short filaments, topped with small antheræ within the tube; the fruit is an oblong, compressed, acuminate capsule, having two cells, and opening with two valves, contrary to the partition, each cell containing an oblong, compressed, pointed seed, with a membranaceous margin.

The lilac is a common shrub, and much admired for the beauty of its leaves and fine bunches of flowers, which come out in May; it is easily propagated from suckers, in which it is very prolific,

these may be taken off in autumn and planted where they are to remain.

**SYRINGA**, is a name more commonly applied to the philadelphus of Linnæus. See the article **PHILADELPHUS**.

**SYRINGE**, an instrument serving to imbibe, or suck in a quantity of any fluid, and to squirt or expel the same with violence.

**SYRUP**, or **SYROP**, in pharmacy, a saturated solution of sugar, made in vegetable decoctions, or infusions.

**SYSSARCOSIS**, in anatomy, a particular species of the kind of articulation, called also symphysis.

**SYSTEM**, *Systema*, in general, denotes an assemblage or chain of principles and conclusions, or the whole of any doctrine, the several parts of which are bound together, and follow or depend on each other; in which sense we say, a system of philosophy, a system of divinity, &c.

**SYSTEM**, in botany, denotes the method of arranging and classing plants according to their similitudes. The most celebrated systems of botany are those of Tournefort and Linnæus; the sexual system of the latter appearing to be the most natural, is therefore followed by all the eminent botanists of this age. See the article **BOTANY**.

**SYSTEM**, in music. See the article **INTERVAL**.

**SYSTOLE**, in anatomy, the contraction of the heart, whereby the blood is drawn out of its ventricles into the arteries; the opposite state to which is called the diastole, or dilatation of the heart.

**SYZYGIA**, *Syzygia*, in astronomy, a term equally used for the conjunction and opposition of a planet with the sun. See **CONJUNCTION**.

# T.

## T A B

**T**, The nineteenth letter, and fifteenth consonant, of our alphabet; the sound of which is formed by a strong expulsion of the breath through the mouth, upon a sudden drawing back of the tongue from the fore part of the palate, the lips being at the same time open.

Among the ancients, T. as a numeral, stood for one hundred and sixty; and with a dash over it, thus  $\overline{T}$ , it signified one hundred and sixty thousand. In music, T stands for tutti, all, or altogether.

TABBY, in commerce, a kind of rich silk, which has undergone the operation of tabbying. See the next article.

TABBYING, the passing a silk or stuff under a calender, the rolls of which are made of iron or copper, variously engraven, which bearing unequally on the stuff, renders the surface thereof unequal, so as to reflect the rays of light differently, making the representation of waves thereon.

TABELLA, tablet, in pharmacy, is much the same with troches and lozenges, being a solid preparation formed into a little cake, or mass, of different figures, intended to dissolve slowly, and generally made agreeable to the palate.

TABERNACLE, among the Hebrews, a kind of building in the form of a tent, set up, by express command of God, for the performance of religious worship, sacrifices, &c. during the journeying of the Israelites in the wilderness; and after their settlement in the land of Canaan, made use of for the same purpose till the building of the temple of Jerusalem.

TABERNÆMONTA, in botany, a genus of plants, whose flower is monopetalous and funnel-shaped; the tube of the corolla is long and cylindric, and the limb is divided into five obtuse oblique segments: the stamina are five small filaments, topped with connivent antheræ: the fruit is composed of two follicles, which are ventricose, acuminate, and

## T A B

horizontally reflexed, formed of one valve, and containing one cell, which is filled with a number of oblong, oval, obtuse, ruff seeds, placed in an imbricated manner, and surrounded with a pulp.

The species of this genus being natives of the West-Indies, and consequently impatient of cold, they therefore require a hot-house in this climate for their preservation.

TABES DORSALIS, in medicine, a distemper which, according to a late author, is a particular species of a consumption, the proximate cause of which is a debility of the nerves. See the article CONSUMPTION.

Of the several kinds of consumptions incident to human bodies, the tabes dorsalis is the slowest in its progress, but the most melancholy in its circumstances; and, unless timely obviated, for the most part fatal.

This disease is only incident to young men of lascivious dispositions, and proceeds from too early venery, an immoderate use of it, or pollutions. It seems, therefore, to derive its origin from too frequent venereal spasms; and the immoderate loss of seminal fluid has a considerable share in producing the effect.

The symptoms of the tabes dorsalis are involuntary, nocturnal, seminal emissions, a pain in the back, and often in the head, a formication of the spine, an aching pain, rolling and hanging down of the testicles, a weakness of memory and sight, and a mucous discharge from the urethra, especially after straining at the discharge of the excrements. The mucous discharge here mentioned, is called by Hippocrates, liquidum semen, but it is nothing but the mucous of the prostrate gland.

This disease is farther attended with great melancholy and dejection of mind, and a gutta serena often follows. The eyes grow hollow, the visage meagre and thin, the body emaciated and weak, a

# T A B

ipation of the heart, and shortness of breath, succeed with a concourse of hectical complaints, ending in death.

For the cure of this distemper, a regularity of the non-naturals is of the utmost importance. Good air, rather cool than hot, is of great use. As to diet, high-seasoned meats, spirituous and fermented liquors, should be avoided. No food is so beneficial as milk: chocolate is also esteemed good, in such quantities as to sit easy on the stomach. Animal food of easy digestion, at dinner, does no harm. Suppers should be avoided, at least milk only should be then taken, about two hours before going to bed. Sleep must be little, and in due season; that is, the patient should go to bed and rise early. Indulgence in bed in a morning is hurtful. The general rule should be to rise immediately upon waking; which, though irksome at first, will by custom be made familiar and agreeable. Moderate exercise, or such as the patient's strength will admit of, without weariness, ought to be used. Some recommend riding, especially a long journey, by such daily portions as to avoid extraordinary fatigue. The secretions of the body, if out of order, should be regulated, and the patient should be entertained with cheerful company.

As to medicines, the classes of balsamics and astringents are chiefly useful. Among the latter, the Peruvian bark, either in substance, extract, or tincture, the acid elixir of vitriol, and the tincture saturnia, or anti-phthysica, are the most efficacious. Strengthening plasters may also be laid on the loins; and, chief of all, the cold bath should be used.

**TABLE**, *Tabula*, a moveable piece of furniture, usually made of wood or stone, and supported on pillars, or the like, for the commodious reception of things placed thereon.

**TABLE**, in architecture, a smooth simple member, or ornament, of various forms, but most usually in that of a long square.

**TABLE**, in perspective, denotes a plain surface, supposed to be transparent, and perpendicular to the horizon.

It is always imagined to be placed at a certain distance between the eye and the objects, for the objects to be represented thereon by means of the visual rays passing from every point thereof through the table to the eye; whence it is called perspective plane.

**TABLES of the Law**, in Jewish antiquity, two tables, on which were written the Decalogue, or Ten Commandments, given by God to Moses on Mount Sinai. See the article **DECALOGUE**.

**TABLE**, among the jewellers. A table-diamond, or other precious stone, is that whose upper surface is quite flat, and only the sides cut in angles; in which sense, a diamond, cut table-wise, is used in opposition to a rose-diamond.

# T A C

**TABLE**, in mathematics, a system of numbers calculated to be ready at hand for the expediting astronomical, geometrical, and other operations: thus we say, tables of the stars; tables of lines, tangents, and secants; tables of logarithms, rhumbs, &c. sexagenary tables; loxodromic tables, &c.

**Astronomical TABLES**, are computations of the motions, places, and other phenomena of the planets, both primary and secondary.

**TABLE**, in heraldry. Coats or escutcheons containing nothing but the mere colour of the field, and not charged with any bearing or moveable, are called *tables d'attente*, tables of expectation, or *tabulæ rase*.

**TABLET**, *Tabella*, in pharmacy. See the article **TABELLA**.

**TABOR**, *Tabourin*, a small drum. See the article **DRUM**.

**TABORITES**, or **THABORITES**, a branch or sect of the ancient Hussites.

They carried the point of reformation farther than Huss had done, rejected purgatory, auricular confession, the unction of baptism, transubstantiation, &c. They reduced the seven sacraments of the Romanists to four, viz. baptism, the eucharist, marriage, and ordination.

**TACAMAHACA**, is the gum of a tall tree, the manner of its growth much resembling the poplar, of which, till lately, it has been held a species: its leaves are for the most part heart-shaped, but some are oval, and others are lanceolated; they are whitish on their under side, and of a dark green on the upper: the flowers are male and hermaphrodite, produced on the same plant, but are not particularly described by botanists.

Tacamahaca is of a fragrant and peculiar smell, and is of two kinds; the one, called the shell-tacamahaca, which is the finest; the other, which is an inferior kind, being termed rough-tacamahaca, or tacamahaca in grains.

Some greatly commend tacamahaca in disorders of the breast and lungs; but at present it is very rarely used internally. Externally, however, it is in repute for softening tumours, and mitigating pain and aches. Applied to the navel, it is said to relieve women in hysterical complaints; and applied in the same manner to the region of the stomach, it assists digestion, and expels flatulences: it is also an ingredient in some of the shop-compositions.

**TACK**, in a ship, a great rope having a wale knot at one end, which is seized or fastened into the clew of the sail; so is reefed first through the chesle-trees, and then is brought through a hole in the ship's side.

Its use is to carry forward the clew of the sail, and to make it stand close by a wind: and whenever the sails are thus trimmed, the main-tack, the fore-tack, and the mizen-tack, are brought close by the

the board, and haled as much forward as they can be.

**TACK-ABOUT**, in the sea language, is to turn the ship about, or bring her head about, so as to lie the contrary way.

**TACKLE**, or **TACKLING**, among sea-men, denotes all the ropes or cordage of a ship, used in managing the sails, &c.

In a more restrained sense, tackles are small ropes running in three parts, having at one end a pendant and a block; and at the other end, a block and hook, to hang goods upon that are to be heaved into the ship or out of it.

**TACTICS**, in the art of war, is the method of disposing forces to the best advantage in order of battle, and of performing the several military motions and evolutions.

**TÆNIA**, in architecture, a member of the Doric capital, resembling a square fillet, or reglet: it serves instead of a cymatium.

**TAFFAREL**, in a ship, the uppermost rail or frame, abaft over the poop. See the article **SHIP**.

**TAFFETY**, in commerce, a fine smooth silken stuff, remarkably glossy.

There are taffeties of all colours, some plain, and others striped with gold, silver, &c. others chequered, others flowered, &c. according to the fancy of the workmen. See **SILK**.

**TAGETES**, the African, or French-marigold, a genus of plants, whose flower is compound and radiated, consisting of hermaphrodite florets, which form the disc, and female ligulated corollulæ, which compose the rays: there is no pericarpium; but the seeds, which are linear and compressed, are contained in the cup.

This genus is one of the finest autumnal beauties which the flower-garden is ornamented with: the plants are raised from seeds, which should be sown in March on a slight hot-bed, and afterwards planted where they are intended to flower.

**TAIL**, *Cauda*, the train of a beast, bird, or fish; which, in land animals, serves to drive away flies, &c. and in birds and fishes, to direct their course, and assist them in ascending and descending in the air or water.

**TAIL of a Comet**, denotes the luminous rays issuing from a comet towards that part of the heavens from whence it seems to move. See **COMET**.

**TAIL of the Trenches**, in the art of war, is the post or place where the besiegers begin to break ground.

**Dragon's TAIL**, in astronomy, the descending node of a planet. See **NODE**.

**TAIL**, or **FEETAIL**, in law, is a limited estate, or fee; opposed to fee-simple. See **FEET**.

Fee-tail is an inheritance whereof a person is seised, to him and the heirs of his body, begotten or to be begotten; so that the tenant in tail cannot alien, either before or after issue had, or forfeit such lands,

longer than for his own life; because an estate in tail always remains to the issue of the donee and his heirs; or in case he has no issue, than to the donor and his heirs.

Estates-tail of lands are either general or special. General tail is where lands or tenements are given to a man or woman, and the heirs of either of their bodies begotten; which is called a general tail, because, however many wives a person that holds by this title shall have one after another in lawful marriage, his issue by them severally are all capable of inheriting in their turns: and if the woman has issue by several husbands, they may all inherit after each other, as heirs of her body. A tail-special, on the other hand, is when lands, &c. are limited to a man and his wife, and the heirs of their two bodies begotten, so that the children by a second wife, or former wife, stand absolutely excluded.

**TALC**, or **TALK**, in natural history, a large class of fossil bodies, composed of broad, flat, and smooth laminæ or plates, laid evenly and regularly on one another; easily fissile, according to the site of these plates, but not all so in any other direction; flexible and elastic; bright, shining, and transparent; not giving fire with steel, nor fermenting with acid menstrua, and sustaining the force of a violent fire without calcining.

**TALENT**, money of account amongst the ancients. See the articles **COIN** and **MONEY**.

Amongst the Jews, a talent in weight was equal to 60 maneh, or 113 lb. 10 oz. 1 dwt. 10 $\frac{1}{2}$  gr.

**TALISMANS**, magical figures cut or engraved with superstitious observations on the characteristics and configurations of the heavens, to which some astrologers have attributed wonderful virtues, particularly that of calling down celestial influences.

There have been some rabbins who maintained, that the brazen serpent raised by Moses, was a talisman.

**TALK**, or **TALC**, in natural history. see the article **TALC**.

**TALLOW**, in commerce, the fat of certain animals, melted down and clarified, so as to be fit for making candles, &c.

**TALLOW-TREE**, a remarkable tree growing in great plenty in China; so called, from its producing a substance like tallow, which serves for the same purpose; it is about the height of a cherry-tree, its leaves in form of a heart, of a deep shining red colour, and its bark very smooth. Its fruit is inclosed in a kind of pod, or cover like a chestnut, and consists of three round white grains, of the size and form of a small nut, each having its peculiar capsula, and within a little stone. This stone is encompassed by a white pulp which has all the properties of true tallow, both as to consistence, colour, and even smell; and accordingly the Chinese make their candles of it; which would doubtless be as good as those in Europe, if they knew how to purify

purify their vegetable, as well as we do our animal, tallow.

All the preparation they give it, is to melt it down and mix a little oil with it, to make it softer and more pliant. It is true their candles made of it yield a thicker smoke, and a dimmer light, than ours; but these defects are owing in a great measure to the wicks, which are not of cotton, but only a little rod, of dry light wood covered with the pith of, a rush wound round it; which, being very porous, serves to filtrate the minute parts of the tallow, attracted by the burning stick, which by this means is kept alive.

**TALLY**, in law, a piece of wood cut in two parts, whereon accounts were anciently kept, by means of notches; one part of the tally being kept by the debtor, and the other by the creditor.

**TALMUD**, or **THALMUD**, among the Jews, a collection of the doctrines of their religion and morality. It is the *corpus juris*, or body of the laws and customs of the Jews, who esteem it equal to the Scriptures themselves.

**TALON**, in architecture, a kind of moulding, which consists of a cymatium, crowned with a square fillet; frequently found to terminate joiners-work, as those of doors, windows, &c.

**TALUS**, in anatomy, the same with the astragalus. See **ASTRAGALUS**.

**TALUS**, or **TALUT**, in architecture, the inclination or slope of a work; as of the outside of a wall, when its thickness is diminished by degrees, as it rises in height to make it the firmer.

**TALUS**, in fortification. Talus of a bastion, or rampart, is the slope or diminution allowed to such a work, whether it be of earth or stone, the better to support its weight.

The exterior talus of a work, is its slope on the side towards the country; which is always made as little as possible, to prevent the enemies scalado; unless the earth be bad, and then it is absolutely necessary to allow a considerable talus for its parapet. The interior talus of a work is its slope on the inside towards the place.

**TAMARINDUS**, the tamarind-tree, in botany; the stem grows to a large size, and is covered with a brown bark; it divides into many branches at the top, which spread wide on every side, and are closely furnished with winged leaves, each composed of sixteen or eighteen pair of folioles, and terminating with an odd one; these are small, a little hairy, and sit close to the midrib. The flowers are produced on the side of the branches, in loose bunches of five or six together, each flower consists of five ovate papilionaceous petals, with three subulated stamina placed in the sinuses of the cup. The fruit is a long, thick, compressed pod, having a double skin and one cell, containing three or four smooth, angular, and compressed seeds, which are

surrounded with an acid stringy pulp of a dark colour.

Tamarinds are brought from Egypt and the East and West-Indies; the pods, membranes, nerves, and seeds, mixed together. They may be propagated in this country, by sowing the seeds on a hot-bed in the spring, and when the plants are come up, should be planted singly in pots, and plunged in the bark bed in the stove, where they must be constantly kept; and, when properly managed, will arise to the height of three feet the first summer.

The pulp, which is the only part used in medicine, is of a cooling nature, it gently relaxes the bowels, temperates the acrimony of the humours, and is good in acute burning fevers; it serves to correct the faults of violent purgatives, and quickens those that are sluggish; it is also recommended in diarrhoeas and nephretic complaints, and is said to cure the jaundice without the assistance of any other medicine.

**TAMARISK**, *Tamariscus*, or *Tamarix*, in botany, a genus of plants, whose flower consists of five ovate, concave, obtuse, patent petals, disposed in the form of a rose; the stamina are five capillary filaments, topped with roundish antheræ; the germen is acuminate, and crowned with three oblong, feathery, twisted stigmas: the fruit is an oblong, triquetous, acute pointed capsule, having one cell and three valves, and contains many small pappose seeds.

There are two species belonging to this genus, one a native of France and the other of Germany; they are both deciduous, and are frequently planted among other shrubs in the pleasure garden. Their propagation here is either by layers or cuttings, which is performed in autumn.

The wood, bark, and leaves of these trees, are accounted specific for all disorders of the spleen, and to attenuate gross humours; but in the present practice are but little used.

**TAMBOUR**, in architecture, a term applied to the Corinthian and Composite capitals, as bearing some resemblance to a drum, which the French call tambour.

**TAMBOUR** is also used for a little box of timber-work covered with a ceiling, within-side the porch of certain churches, both to prevent the view of persons passing by, and to keep off the wind, &c.

**TAMBOUR** also denotes a round course of stone, several whereof form the shaft of a column, not so high as a diameter.

**TAMPION**, or **TOMPION**, among gunners, a plug to stop the mouths of cannons, mortars, &c. to keep them clean within.

**TAMUS**, black-briony, in botany, a genus whose flowers are male and female, and produced on separate plants, neither having any corolla; the cup

cup of the male flower is divided into six parts, and contains the same number of stamina; the cup of the female flower is monophyllous, campanulated, and patent, and divided into six lanceolated segments, with oblong punctuated nectaria placed on the inside of its edges; the fruit is an ovate, trilobular berry, containing two globose seeds.

**TAN**, the bark of the oak, chopped and ground, in a tanning-mill, into a coarse powder, to be used in the tanning of leather.

New tan is the most esteemed; for when old and stale, it loses a great deal of its effects, which consists in condensing and closing the pores of the skin, so that the longer the skins are kept in tan, the greater strength and firmness they acquire. In effect, not only the bark, but every part of the oak-tree, of what age and growth soever, and all oaken coppice, &c. cut in barking-time, make good tan, as good at least as the best bark. This when got, is to be well dried in the sun, housed dry, and kept so. When it is to be used, the greater wood must be shaved small, or cut for the tan engine, and the smaller bruised, or cut small by the engine, after which it must be dried on a kiln, &c.

**TAN**, among gardeners, for the use of which see the articles **BARK**, **FORCING**, **HOT-HOUSE**, &c.

**TANACETUM**, *Tansy*, in botany, a genus of plants, whose flower is compound, tubulose, and convex, and contained in an hemispherical imbricated cup; the corollulæ of the disc are hermaphrodite, funnel-shaped, and quinquefid at the limb; the female florets which compose the rays are trifid and deeply divided within; there is no pericarpium, but the seeds, which are solitary, oblong, and naked, are contained in the cup, and placed on a convex, naked receptacle.

The common tansy grows wild in many parts of England, and is also cultivated in gardens; the root is long, woody, fibrous, and perennial; the stalks arise to the height of two or three feet, they are streaked, a little hairy, and pithy; the leaves are large, long, winged, serrated on their edges, and disposed in pairs along the midrib, and terminated with an odd one. The flowers grow in umbels on the extremities of the stalks, they are of a yellow colour, and come out in July.

The leaves of tansy have an acrid, bitter, aromatic taste, and are looked upon as stomachic, febrifuge, and sudorific, as well as anthelmintic, for both the leaves and seeds have always been accounted good to kill worms; it is therefore often substituted instead of worm-seed, but is not so efficacious.

**TANGENT**, in geometry, is defined, in general, to be a right-line, which touches any arch of a curve in such a manner, that no right line can be drawn through betwixt the right line and

the arch, or within the angle that is formed by them.

The tangent of an arch is a right-line drawn perpendicularly from the end of a diameter, passing to one extremity of the arch, and terminated by a right-line drawn from the center through the other end of the arch, and called the secant. See **SECANT** and **SINE**.

And the co-tangent of an arch, is the tangent of the complement of that arch. See **ARCH** and **COMPLEMENT**.

The tangent of a curve is a right-line which only touches the curve in one point, but does not cut it.

**TANNER**, one who dresses hides, &c. by tanning them. See the next article.

**TANNING**, the preparing of skins or hides in a pit, with tan and water, after the hair has been first taken off, by putting the skins into lime water. See the articles **SKIN**, **HIDE**, &c.

*Method of TANNING Oxen Hides.* The skin being flayed off the carcase, if it is intended to be kept, is salted with sea-salt and alum, or with a coarse kind of salt-petre. If it is not for keeping, the salting is saved, as being of no use but to prevent the hide from corrupting before it can be conveniently carried to the tan-house. Whether the hide have been salted or not, the tanner begins with taking off the horns, the ears, and the tail, after which it is thrown into a running water for about thirty hours, to wash off the blood and other impurities adhering to the inside. This done it is laid over-night in a lime-pit, already used, whence it is taken and left to drain three or four days on the edge of the pit. The first and slightest preparation over, it is retained in a strong lime-pit for two days, then taken out for four days more; and thus for six weeks alternately, it is taken out and put in twice a week. At the six weeks end it is put into a fresh pit, where it continues eight days, and is then taken out for so many, and thus alternately for a year or eighteen months, according to the strength of the leather and the weather; for in great heats they put in fresh lime twice a week; and in frost they sometimes do not touch them for three months. Every fresh lime-pit they throw them into, is stronger and stronger. At the end of four, five, or six weeks, the tanner scrapes off the hair on a wooden leg or horse, with a kind of knife made for that purpose. And after a year or eighteen months, when the hair is perfectly gone, he carries it to a river to wash, pares off the flesh on the leg with a kind of cutting-knife, and rubs it briskly with a sort of whetstone, to take off any remains of flesh or of filth on the side of the hair. The skin is now put in tan, that is, it is covered with tan as it is stretched in the pit, and water is let in upon it; if the skin is strong, five coverings of tan will be required;

required; for weaker, three or four may suffice. When the skin has not been kept long enough in lime, or in the tan-pit, upon cutting it in the middle, there appears a whitish streak, called the horn or crudity of the skin, and it is this crudity that is the reason why the soles of shoes, boots, &c. stretch so easily and take water. When the hides are sufficiently tanned, they are taken out of the pit to be dried, by hanging them in the air; then the tan is cleared off them, and they are put into a place neither too dry nor too moist; they are there well stretched over one another with weights a-top, to keep them tight and strait; and in this condition are sold under the denomination of bend-leather. This is the method of tanning bullocks or oxen hides. Cows, calves, and horses skins are tanned much after the same manner of those of oxen, except that they are only kept four months in the lime-pit, and that before they be put in the tan, there is a preparation required thus: cold water is poured into a wooden vat, or tub, wherein the skins are put, which are kept stirring while some other water is warming in a kettle; and as soon as that water is little more than luke-warm, it is poured gently into the vat, and upon this is cast a basket of tan; during which time the skins are still kept turning, that the water and tan may not scorch them. After an hour they are taken out and cast for a day into cold water, then returned to the former vat and the same water they had been in before, and here they are left for eight days; which expired, they are put into the tan-pit, and three coverings of tan given them; the first of which lasts five weeks, the second six, and the third two months. The rest of the process is the same in all respects as that delivered above.

**TANSEY**, *Tanacetum*, in botany. See the article **TANACETUM**.

**TANTALUS's CUP**, in hydraulics, a siphon so adapted to a cup, that the short leg being in the cup, the long leg may go down through the bottom of the cup. See the article **SIPHON**.

This bended siphon is called Tantalus's cup, from the resemblance of the experiment made with an image in the glass, representing Tantalus in the fable, fixed up in the middle of the cup with a siphon concealed in his body, beginning in the bottom of his feet, and ascending to the upper part of his breast; there it makes a turn, and descends through the other leg, on which he stands; and from thence down through the bottom of the cup, where it runs out, and causes the water to subside in the cup; as soon as it rises to the height of the siphon, or to the chin of the image, the water will begin to run through the siphon concealed in the figure, till the cup is emptied.

**TANTAMOUNT**, something that amounts, or is equivalent, to some other.

**TAP**, among hunters, an hare is said to tap or beat, when she makes a particular noise at rutting-time.

**TAP-ROOT**, among gardeners, that part of the root that descends straight down.

**TAPESTRY**, or **TAPISTRY**, a curious kind of manufacture, serving to adorn a chamber or other apartment, by covering or lining the walls thereof. It is a kind of woven hangings of wool and silk, frequently raised and enriched with gold and silver, representing figures of men, animals, landscapes, histories, &c.

The invention of tapestry seems to have come to us from the Levant; and this seems the more probable, in that the workmen concerned in it were called, at least in France, *Sarrafins*, or *Sorrosinois*.

It is supposed that the English and Flemish, who were the first that excelled in making tapestry, might bring the art with them from some of the croisades, or expeditions against the Saracens. Be this as it will, it is certain that these two nations, especially the English, were the first who set on foot this noble and rich manufacture in Europe, now one of the finest ornaments of palaces, churches, &c. and therefore if they may not be allowed the inventors, they have at least the glory of being the restorers of this so curious and admirable an art, as gives a kind of life to wools and silks, in no respect inferior to the paintings of the best masters.

Tapestry-work is distinguished by the workmen into two kinds, viz. that of high and that of low warp; though the difference is rather in the manner of working than in the work itself; which is in effect the same in both; only the looms, and consequently the warps, are differently situated. Those of the low warp being placed flat and parallel to the horizon; and those, on the contrary, of the high warp, erected perpendicularly. The English anciently excelled all the world in the tapestry of the high warp, and they still retain their former reputation, though with some little change: their low warps are still admired; but, as for the high ones, they are quite laid aside by the French.

The French have three considerable tapestry-manufactures besides that of the Gobelins; the first at Aubusson in Auvergne, the second is at Felletin in the Upper Marche, and the third at Beauvais. They were all equally established for the high and low warp; but they have all laid aside the high warp, excepting the Gobelins. There are admirable low warps in Flanders, generally exceeding those of France; the chief and almost only Flemish manufactures are at Brussels, Antwerp, Oudenard, Lisle, Tournay, Bruges, and Valenciennes.

The usual widths of tapestries are from two ells to three ells Paris-measure.

*The Manufacture of TAPESTRY of the High Warp.*

The loom, whereon it is wrought, is placed perpendicularly:

pendicularly: it consists of four principal pieces; two long planks or cheeks of wood, and two thick rollers or beams. The planks are set upright, and the beams across them, one at the top, and the other at the bottom, or about a foot distance from the ground. They have each their trunnions, by which they are suspended on the planks, and are turned with bars. In each roller is a groove from one end to the other, capable of containing a long round piece of wood, fastened therein with hooks. The use of it is to tie the ends of the warp to. The warp, which is a kind of worsted, or twisted woollen thread, is wound on the upper roller; and the work, as fast as wove, is wound on the lower. Within the planks, which are seven or eight feet high, fourteen or fifteen inches broad, and three or four thick, are holes pierced from top to bottom, in which are put thick pieces of iron, with hooks at one end, serving to sustain the coat-stave; these pieces of iron have also holes pierced, by putting a pin in which, the stave is drawn nearer or set further off; and thus the coats or threads are stretched or loosened at pleasure. The coat-stave is about three inches diameter, and runs all the length of the loom; on this are fixed the coats or threads, which make the threads of the warp cross each other. It has much the same effect here, as the spring-stave and treddles have in the common looms. The coats are little threads fastened to each thread of the warp with a kind of sliding knot, which forms a sort of mash or ring. They serve to keep the warp open for the passage of broaches wound with silks, woollens, or other matters used in the piece of tapestry. In the last place, there are a number of little sticks of different lengths, but all about an inch in diameter, which the workman keeps by him in baskets, to serve to make the threads of the warp cross each other, by passing them across: and, that the threads thus crossed may retain their proper situation, a packthread is run among the threads, above the stick.

The loom being thus formed, and mounted with its warp, the first thing the workman does, is to draw on the threads of this warp, the principal lines and strokes of the design to be represented on the piece of tapestry; which is done by applying cartoons, made from the painting he intends to copy, to the side that is to be the wrong side of the piece, and then, with a black-lead pencil, following and tracing out the contours thereof on the thread of the right side; so that the strokes appear equally both before and behind.

As for the original design the work is to be finished by, it is hung up behind the workmen, and wound on a long staff, from which a piece is unrolled from time to time, as the work proceeds.

Besides the loom, &c. here described, there are three other principal instruments required for working the silk or the wool of the wool within the

threads of the warp; these are a broach, a reed, and an iron needle.

The broach is made of a hard wood, seven or eight inches long, and two thirds of an inch thick, ending in a point with a little handle. This serves as a shuttle; the silks, woollens, gold, or silver to be used in the work, being wound on it.

The reed or comb is also of wood, eight or nine inches long, and an inch thick on the back, whence it grows less and less to the extremity of the teeth, which are more or less apart, according to the greater or less degree of fineness of the intended work. Lastly, the needle is made in form of the common needle, only higher and longer. Its use is to press close the wool and silks when there is any line or colour that does not fit well.

All things being prepared for the work, and the workman ready to begin, he places himself on the wrong side of the piece, with his back towards the design; so that he works as it were blind-fold, seeing nothing of what he does, and being obliged to quit his post, and go to the other side of the loom, whenever he would view and examine the piece, to correct it with his pressing needle. To put silk, &c. in the warp, he first turns and looks at the design, then, taking a broach full of the proper colours, he places it among the threads of the warp, which he brings cross each other with his fingers, by means of the coats or threads, fastened to the staff; this he repeats every time he is to change his colour. Having placed the silk or wool, he beats it with his reed or comb; and when he has thus wrought in several rows over each other, he goes to see the effects they have, in order to reform the contours with his needle, if there be occasion. As the work advances, it is rolled upon the lower beam, and they unroll as much warp from the upper beam, as suffices them to continue the piece: the like they do of the design behind them. When the pieces are wide, several workmen may be employed at once.

We have but two things to add: the first is, that the high warp tapestry goes on much more slowly than the low-warp, and takes up almost twice the time and trouble. The second is, that all the difference that the eye can perceive between the two kinds, consists in this, that in the low-warp there is a red fillet, about one twelfth of an inch broad, running on each side from top to bottom, which is wanting in the high-warp.

#### *The Manufacture of TAPESTRY of the Low Warp.*

The loom or frame wherein the low-warp is wrought, is much like that of the weavers; the principal parts thereof are two strong pieces of wood, forming the sides of the loom, and bearing a beam or roller at each end; they are sustained at bottom with other long pieces of wood, in manner of tressels: and, to keep them the firmer, are likewise fastened to the floor, with a kind of buttresses, which prevent any shaking, though there are sometimes

times four or five workmen leaning on the beam at once. The rollers have each their trunnions, by which they are sustained; they are turned by large iron pins, three feet long. Along each beam runs a groove, in which is placed the wich, a piece of wood about two inches diameter, and almost the length of the roller. This piece fills the groove intirely, and is fastened therein, from space to space, by wooden pins. To the two wiches are fastened the two extremities of the warp, which is wound on the further roller, and the work, as it advances, on the nearer. Across the two sides, almost in the middle of the loom, passes a wooden bar, which sustains little pieces of wood, not unlike the beam of a balance: to these pieces are fastened strings, which bear certain spring staves, wherewith the workman, by means of two treddles under the loom, on which he sets his feet, gives a motion to the coats, and makes the threads of the warp rise and fall alternately. Each loom has more or fewer of these spring-staves, and each staff more or fewer coats, as the tapestry consists of more or fewer threads. The design or painting the tapestry-man is to follow, is placed underneath the warp, where it is sustained from space to space with strings, by which the design is brought nearer to the warp. The loom being mounted, there are two instruments used in working of it, viz. the reed and the flute.

The flute does the office of the weaver's shuttle: it is made of a hard polished wood, three or four lines thick at the ends, and somewhat more in the middle, and three or four inches long. On it are wound the silks, or other matters, to be used as the woof of the tapestry, represented. The comb, or reed, is of wood or ivory: it has usually teeth on both sides; it is about an inch thick in the middle, but diminishes each way to the extremity of the teeth; this serves to beat the threads of the woof close to each other, as fast as the workman has passed and placed them, with his flute, among the threads of the warp.

The workman is seated on a bench before the loom, with his breast against the beam, only a cushion or pillow between them; and in this posture separating with his fingers the threads of the warp, that he may see the design underneath; and taking a flute, wound with the proper colour, he fastens it among the threads, after having raised or lowered them, by means of the treddles, moving the spring staves and coats.

Lastly, to press and close the threads of the silk or yarn, &c. thus placed, he strikes each course (i. e. what the flute leaves in its passing and coming back again) with the reed.

That which is very remarkable in the manufacture of the low-warp, and which is common to it with the high, is, that it is all wrought on the wrong side; so that the workman cannot see the

right side of his tapestry until the piece is finished, and taken out of the loom.

**TAPLINGS**, in the English salt-works, the name given to certain bars of iron, which support the bottom of the pan in which the brine is boiled. See the article **SALT**.

**TAPPING**, in agriculture, is the making an incision in the bark of a tree, and letting out the juice.

To tap a tree at the root, is to open it round about the root.

One of the most effectual ways of tapping, so as to obtain the greatest quantity of sap, and that in the shortest time, is not only to pierce the bark, or to cut the body of the tree almost to the pith with a chissel, but to bore through all the circles on both sides the pith, leaving only the outermost circle and the bark on the north-east side unpierced.

This hole is to be bored sloping upwards, as large as the largest auger will make; and that also through and under a large arm near the ground; and thus it will not need any stone to keep open the orifice, nor tap to direct the sap into the receiver.

**TAR**, a thick, black, unctuous substance, obtained from old pines and fir-trees, by burning them with a close smothering heat: for the method of obtaining which, and the use of it in coating and caulking ships, &c. see the article **PITCH**.

With regard to the medical uses of tar, it may be observed, that it differs from the native resinous juice of trees, in having received a disagreeable impression from the fire, and containing a portion of the saline and other juices, united with the resinous and oily; by the mediation of these, a part of the terebinthinate oil proves dissoluble in aqueous liquors, which extract little or nothing from the purer turpentine.

Water impregnated with the more soluble parts of tar, proves, in consequence of this hot pungent oil, warm and stimulating: it sensibly raises the pulse, and quickens the circulation. By these qualities, in cold, languid, phlegmatic habits, it strengthens the solids, attenuates viscid juices, opens obstructions of the minuter vessels, and promotes perspiration and the fluid secretions in general; whilst in hot bilious temperaments, it disposes to inflammation, and aggravates the complaints which it has been employed to remove.

Tar-water has lately been recommended to the world as a certain and safe medicine in almost all diseases; a slow, yet effectual, alternative in cachexies, scurvies, chlorotic, hysterical, hypochondriacal, and other chronical complaints; and a sudden remedy in acute distempers, which demand immediate relief, as pleurifies, peripneumonies, the small-pox, and all kinds of fevers in general.

This medicine, though inferior to the character given it, is, doubtless, in many cases, of considerable utility. It sensibly raises the pulse, and occa-

sions some considerable evacuations, generally by perspiration or urine, though sometimes by stool or vomit: hence it is supposed to act by encreasing the vis vitæ, and enabling nature to expel the morbid humours.

We shall here insert, from the first public recommender of this liquor, Bishop Berkley, some observations on the manner of using it: Tar-water, when right, is not paler than French, nor deeper than Spanish white-wine, and full as clear; if there be not a spirit very sensibly perceived in drinking, you may conclude the tar-water is not good. It may be drank either cold or warm; in cholics it is judged to be best warm. As to the quantity, in common chronical indispositions, a pint a day may suffice, taken on an empty stomach, at two or four times, to wit, night and morning, and about two hours after dinner and breakfast: more may be taken by strong stomachs. But those who labour under great and inveterate maladies, must drink a greater quantity, at least a quart every twenty-four hours: all of this class must have patience and perseverance in the use of this, as well as of all other medicines, which, though sure, must yet, in the nature of things, be slow in the cure of inveterate and chronical disorders. In acute cases, and fevers of all-kinds, it must be drank in bed, warm, and in great quantity (the fever still enabling the patient to drink) perhaps a pint every hour; which has been known to work surprising cures. But it works so quick, and gives such spirits, that the patients often think themselves cured before the fever hath quite left them.

Tar-pills are directed, in the Edinburgh Dispensatory, to be prepared as follows: Take of tar, any quantity at pleasure, mix it with as much elecampane-root as will reduce it into a proper thickness for being formed into pills. The powder here mixed with it, though of no great virtue, is, nevertheless, a very useful addition, not only for procuring it a due consistence for taking, but likewise, as it divides the glutinous texture of the tar, and thus prevents its adhering to the intestines, and promotes its solubility in the animal juices. Each dram of the mass is formed into twelve pills, six of which are taken every morning and evening, in disorders of the breast, phthises, scurvis, &c. They are far more different in quality from tar-water than might be at first expected; that nauseous draught has little heat, pungency, and bitterness: the water extracting only a small quantity of the hot oil, which becomes soluble by the mediation of the acid, produced in the preparation of the tar.

Some have imagined this acid to be the oily substance that gives virtue to tar-water; and hence have endeavoured to introduce an acid spirit, obtained from tar by distillation; but the effects of this, and all other acids, are directly contrary to those

experienced, either from tar-water, or tar given in substance.

Barbadoes-tar is nearly of the consistence of common tar, and of a reddish black colour, and disagreeable smell. This bitumen is found in several of our American islands, where it is esteemed, by the inhabitants, of great service as a sudorific, and in disorders of the breast and lungs; though in cases of this kind, attended with inflammation, it is certainly improper. They also apply it externally as a discutient, for preventing paralytic disorders. Among us it is rarely used, and not often to be met with genuine. The college employ it as a menstruum for sulphur, in the Barbadoes balsam of sulphur; and direct an oil to be distilled from it.

TARANTISMUS, in medicine, the disease or affection of those bit by the tarantula.

The patients under this malady are denominated tarantati. See the next article.

TARANTULA, in the history of insects, a species of araneus, with an oval hairy body and thick legs. See the article ARANEUS.

This is one of the large spiders, but is not the very largest known: its body is three quarters of an inch long, and of the thickness of one's little-finger: it is usually of an olive brown, variegated with a dusky colour; but in this it varies greatly: it is covered with a short and soft down, or hairiness; the points of its forceps are very fine and sharp: this species is a native of Apulia.

As to the effects of the poison they convey into the wound they make, there seems yet room for much explanation about it. We are told, that in the summer months, especially when the heats are greatest (as in the dog-days) the tarantula, creeping among the corn in the fields, bites the mowers and passengers: that in the winter it lurks in holes, and is scarcely seen; and that, if it bites then, it is not so venomous, neither does it induce any ill symptoms: but in hot weather, according to Dr. Mead, although the pain of its bite is at first no greater than what is caused by the sting of a bee, yet the part is quickly after discoloured with a livid, black, or yellowish circle, and raised to an inflamed swelling; the patient, within a few hours, is seized with a violent sickness, difficulty of breathing, universal faintness, and sometimes trembling, with a weakness in the head; and on being asked his ailment, with a tremulous voice, and melancholy look, points to his breast, as if the heart was most affected: the patient grows by degrees more melancholy, stupid, and strangely timorous, and in a short time expires, unless music is called to his assistance, which alone, without the help of medicines, is said to perform the cure, the usual alexipharmics and cordial medicines, being of no service.

At the first sound of the musical instrument, although the sick lie as it were in an apoplectic

fit, they begin, by degrees, to move their hands and feet, till at last they get up, and fall to dancing, with wonderful vigour at first, for three or four hours; then they are put to bed, refreshed from their sweating a short time, and repeat their exercise with the same vehemence, perceiving no weariness or weakness from it, but professing that they grow stronger and nimbler the more they dance.

At this sport they usually spend twelve hours a day, and it continues three or four days, by which time they are freed from all their symptoms; which, nevertheless, attack them about the same time next year; and if they do not take care to prevent this relapse by music, they fall into the jaundice, want of appetite, universal weaknesses, and such like diseases, which are every year increased if dancing be neglected, till at last they prove incurable.

As music is the common cure, so they who are bitten are pleased, some with one sort of it, and some with another; one is pleased with a pipe, another with a timbrel; one with a harp, and another with a fiddle; so that the musicians sometimes make several essays before they can accommodate their art to the venom: but this is constant and certain, notwithstanding this variety, that they all require the quickest tunes; and are never moved by a slow dull harmony.

While the tarantati are dancing, they lose in a manner the use of all their senses, are like so many drunkards, do many ridiculous and foolish tricks, talk and act obscenely and rudely, take great pleasure in playing with vine-leaves, with naked swords, red cloaths, and the like; and, on the other hand, cannot bear the sight of any thing black, so that if any by-stander happen to appear in that colour, he must immediately withdraw, otherwise they relapse into their symptoms with as much violence as ever.

Baglivi, who resided in Italy (and probably had good opportunities of informing himself with respect to this insect) has written a treatise expressly upon the subject: and most medicinal writers mention the distempers arising from the bite thereof, as a thing certain.

But, notwithstanding all these great authorities, there is good reason to believe the whole story fabulous, and a vulgar error; for it is treated as such by an Italian physician, in the *Philos. Transact.* and a great many gentlemen of unquestionable veracity, who resided at Taranto many months, and during the time in which the bite of a tarantula is said to be most pernicious, affirm, that there was not a physician in the country, who believed there ever was such a distemper, from such a cause: that among the vulgar there is a tradition, that distempers attended with very extraordinary circumstances, had been excited by the bite of a tarantula; but that nobody ever remembers a single instance; and that

there is no other spider to be found in that country, different from those which are common in most warm countries.

**TARCHONANTHUS**, in botany, a genus of plants, whose flowers are compound and uniform, and contained in a turbinate cup; the proper flower is hermaphrodite, monopetalous, and funnel-shaped: the seeds are solitary, of an oblong figure, topped with down, and contained in the cup.

**TARCHONANTHUS**, is also a name used by Vaillant for the iva of Linnæus. See the article **IVA**.

**TARE**, is an allowance for the outside package, that contains such goods as cannot be unpacked without detriment; or for the papers, threads, bands, &c. that inclose or bind any goods imported loose; or, though imported in casks, chests, &c. yet cannot be unpacked and weighed net.

Several sorts of goods have their tares ascertained, and those are not to be altered or deviated from, in any case, within the port of London; unless the merchant, thinking himself or the officers of the crown, to be prejudiced by such tares, shall desire that the goods may be unpacked, and the net-weight taken; which may be done either by weighing the goods in each respective cask, &c. net; or (as is practised in East-India goods particularly) by picking out several casks, &c. of each size, and making an average, compute the rest accordingly. But this must not be done without the consent of two surveyors, attested by their hands in the land-waiter's books; and in the out-ports, not without the consent of the collector and surveyor. And to those goods which have not their tares ascertained, two surveyors in London, and the collector and surveyor in the out-ports, are to adjust and allow the same, in like manner.

Sometimes the casks, &c. are weighed beyond sea, before the goods are put in; and the weight of each respective cask, &c. marked thereon (as is usual for most goods imported from the British plantations) or else inserted in the merchant's invoice; in which case, if the real invoice be produced, and the officers have satisfied themselves (by unpacking and weighing some of them) that those weights are just and true, they do then, after having reduced them to British weight, esteem them to be real tares, and pass them accordingly.

But the unpacking goods, and taking the net-weight, being supposed the justest method, both for the crown and merchant, it is usually practised in the port of London, in all cases where it can be done with conveniency, and without detriment to the goods.

**TARE**, in botany, a species of visia. It is an annual plant; the root is slender and fibrous, with weak, angular, hairy, and hollow stalks; the leaves

## T A R

are composed of several pair of blunt hairy folioles, and terminated with a tendril, which lays hold on any thing next it for its support; the flowers are papilionaceous, and of a purple or bluish colour; these are succeeded by hairy erect pods, containing in each, three or four round seeds.

This plant is sowed in the fields almost all over Europe, for provender for cattle, either when the plant is green or dried; also the seeds of the latter, pigeons and hogs are very fond of.

In medicine, tares are reckoned diaphoretic, and are sometimes used in cataplasms to soften, resolve, and strengthen.

**TARGIONIA**, in botany, a genus of cryptogamous plants, the flower-cup of which is almost globular, and consists of two valves; and the anthera is sessile, campanulated, and placed in the bottom of the cup.

**TARGUM**, a name whereby the Jews call the Chaldee paraphrases, or expositions, of the Old Testament, in the Chaldee language.

**TARIF**, or **TARIFF**, a table or catalogue, containing the names of different sorts of merchandize, with the duties to be paid, as settled by authority, among trading nations.

**TARPAULIN**, a piece of canvas well tarred over, to keep off the rain from any place.

The term is also often applied, in a burlesque sense, to a person that has been all his life bred to the sea.

**TARPEIAN**, in Roman antiquity, an appellation given to a steep rock in Rome; whence, by the law of the twelve tables, those guilty of certain crimes were precipitated.

**TARPEIAN GAMES**, the same with those otherwise called capitoline. See **CAPITOLINE GAMES**.

**TARSO**, in the glass-trade, a white kind of stone, used instead of sand, for the finest crystal glass. See the article **GLASS**.

**TARRAGON**, in botany, the English name for a species of artemisia. See **ARTEMISIA**.

The leaves somewhat resemble those of hyssop, and are of a dark-green colour, and the flowers grow on the tops of the branches in bunches.

The whole plant is very acrimonious, and is aperient, diuretic, and proper to open obstructions: by some it is mixed with salads, to correct the coldness and crudities of other herbs, and because it is good for cold stomachs.

**TARSUS**, in anatomy, the space between the bones of the leg and the metatarsus, wherein are contained seven bones, viz. the astragalus, calcaneum, os naviculare, os cuboides, and the three ossa cuneiformia. See the articles **ASTRAGALUS**, **CALCANEUM**, &c.

**TARTANE**, in naval architecture, a kind of bark, used in the Mediterranean, for fishing and carriage.

## T A R

It has only a main mast and a mizzen; its sails are triangular; and when a square sail is put up, it is called a fail of fortune.

**TARTAR**, in natural history and pharmacy, a hard and almost stony separation from a vegetable juice, after fermentation.

The common tartar is the produce of wine, being found in large masses, adhering to the bottoms and sides of the casks, in which that liquor has been long kept. We meet with it in large masses of an irregular figure, and more or less dense texture, without smell, and of a subacid taste.

The common crude tartar is of two kinds, the white and the red; this difference of colour, being owing to that of the wine they are produced from, is of little consequence in itself, but it is an indication of more essential differences in the matter.

The white tartar is much more pure and clean than the red, and is, though equally hard, considerably less heavy. We have this principally from Germany, where it is, at times, cleared off from the sides of very large vessels, in which they keep their white-wines for many years.

The red tartar is brought in large quantities from Italy, and some parts of France. The white tartar is to be chosen for medicinal use, and particularly such as is of a compact texture, not spongy or cavernous, when broken, and free from dirt, or other foulnesses, and such as has a sort of crystallizations on its surface.

Tartar is, properly speaking, the essential salt of the grape.

Tartar contains a large portion of acid salt, and of an oil, in part thin and limpid, in part thick and coarse. It affords a small portion of a volatile alkali salt in distillation, and the residuum yields a very large proportion of fixed alkali.

It is to be observed, that both these alkalies seem, in some degree, creatures of the fire; for neither of them manifest themselves either by their taste or qualities in the tartar, any more than in many other substances, which yet afford much of them by analysis, till they have felt the operation of the fire.

Tartar dissolves in boiling water, but with great difficulty in cold; and even when purified, and brought to the state of what we call crystal, or cream-of-tartar, it retains the same quality.

Tartar is scarce ever given internally in its crude state. The preparations now in use are the following:

**Crystals of TARTAR.** Powder a quantity of white tartar, and boil it in a sufficient portion of water till it be in a great part dissolved, the foulness only remaining behind. Pour this decoction, while hot, through a flannel bag, let it stand till cold, and there will be crystals formed at the sides of the vessel; these are the crystals of tartar. They may be

## T A R

be dissolved by boiling a second time, and set to shoot again, and by this means they will be rendered the more pure. The French, who prepare great quantities of these crystals about Montpellier, first dissolve a small quantity of white earth of the nature of chalk, in the water in which they are to be boiled, for the second solution. This earth renders the water milky, but the crystals shoot perfectly clear in in, and whatever foulness they carried with them at their first shooting, will be, by this means, more perfectly separated from them.

It was formerly a custom to separate first the salt which shot to the top of the liquor in form of a thin skin or film, and this was supposed purer than the rest, and called cream of tartar; but it is wholly the same with the crystals that shoot to the sides of the vessel, and nobody now trouble themselves to keep it separate.

The crystals of tartar, or, as we commonly express it, cream of tartar, is a gentle purge; it attenuates and resolves tough humours, and is good against obstructions of the viscera, and against cachectic complaints.

*Fixed Salt of TARTAR.* Take any quantity of tartar at pleasure, put it into a crucible, and calcine it for eight hours in an open fire; then pour boiling water on it, and set it over the fire till all the salt be dissolved. Filtre the solution, and evaporate it to a dryness in a sand-heat; there will remain, at the bottom of the vessel, a white fixed alkaline salt. If it is not so pure as it ought to be, dissolve it in fair water; filtre the solution, and evaporate it to a dryness as before; after which it may be calcined for half an hour in a crucible; it will then be perfectly pure, and must then be kept in a phial close stopped, for it easily melts if the air comes to it.

If this salt be exposed to a damp air, as in a vault, or other such place, in a flat earthen vessel, it runs into a heavy liquor, which is to be filtered, to separate it from any foulness it may have accidentally contracted, and is the oleum tartari per deliquium.

The fixed salt of tartar is very acrid and caustic; some attribute great virtues to it, as a diuretic; and our apothecaries too frequently use it in the place of salt of wormwood. They, indeed, buy it as such; and what is yet more unfair in the seller, is, what he calls by either of these names of salt of tartar or salt of wormwood, as it is more or less purified, is often not truly either, but is prepared from the common Russia pot-ash, dissolved and purified. This fixed alkali is of great use in opening the bodies of resinous and sulphureous subjects, and making them yield a stronger tincture to spirit of wine, or water, than they otherwise would do. It is often mixed also with purges to quicken the operation. Caution ought to be taken, when it is given internally, either that it be first dissolved by an acid, as in the saline draughts; or else blended with a large

## T A R

quantity of liquor, to prevent its proving too acrid as it passes the oesophagus.

*Tincture of Salt of TARTAR.* Put a quantity of salt of tartar into a good crucible; set it in an open fire, and calcine it for some hours, raising the fire, at last, to such a degree as to make the salt ready to melt; then pour it into a clean marble mortar, grind it some time, and while yet hot, put it into a matras heated beforehand; pour a quart of rectified spirits of wine on four ounces of this calcined salt, and let it stand in a sand-heat three or four days, in which time, if the process have been rightly managed, the spirit will become of a strong yellowish colour, and is then to be filtered off for use.

People who make this tincture, find it difficult to give the spirit the true colour. This tincture is attenuant and resolvent, given from ten to thirty drops: it is also of great use in extracting the tinctures of vegetable and mineral substances, which would not impart any colour to simple spirit of wine.

*Foliated TARTAR, or Regenerated TARTAR.*

Take any quantity of dry salt of tartar powdered, put it into a large glass vessel, and pour thereon, by degrees, as much spirit of vinegar as will saturate the salt; filtre the fluid, and evaporate it over a gentle fire to dryness, taking great care that the matter does not contract any empyreuma. On the salt which remains after this evaporation, pour out as much fresh vinegar as will again saturate it; then filtre the fluid, and carefully dry it by evaporation.

This salt has a febrifuge and deobstruent quality. The dose may be from ten grains to one scruple, to be taken in a glass of water, and repeated every fourth or sixth hour, according to the exigence of the case.

*Emetic TARTAR*, a preparation of antimony with tartar. See ANTIMONY.

*Soluble TARTAR* is thus made: Dissolve a pound of fixed alkaline salt in a gallon of boiling-water, and gradually throw in crystals of tartar as long as a fresh addition thereof raises any effervescence, which generally ceases before three pounds of the crystals have been used: then filtre the liquor; and, after due evaporation, set it by to crystallize. This salt has been long esteemed both as a medicine and a menstruum: it is aperient, attenuates viscid juices, promotes the urinary secretion, and gently loosens the belly: the dose is from ten grains to a dram or two, or more. It is also used as an addition to the resinous purgatives, as it promotes their action, and at the same time prevents their griping quality.

*Vitriolated TARTAR* is ordered, by the College of London physicians, to be made thus: Dissolve eight ounces of green vitriol in four pints of boiling water; and while the liquor continues boiling,

throw

T-A-U-R-U-S II.

J. Lodge Sculp.

throw into it salt of tartar, or any other alkaline salt, till no effervescence arises upon throwing in a fresh addition, which generally happens when four ounces, or a little more of the salt have been used: filtre the liquor through paper, and after due evaporation set it by to crystallize.

Vitriolated tartar is aperient, exhibited in small doses of a scruple, or half a dram, attenuates viscid juices, and promotes the fluid secretion. In large doses it proves a mild and safe cathartic.

TASSEL, a sort of pendant ornament at the corners of a cushion, or the like.

In building, tassels denote those pieces of board that lie under the ends of the mantle-trees.

TASTE, in physiology, a peculiar sensation excited by means of the organs of taste, viz. the papillæ of the tongue. See the article TONGUE.

The tastes of bodies depend on a certain determinate magnitude of their particles, adapted to excite different sensations by means of the papillæ of the tongue.

Savours, which are the objects of the taste in general, proceed chiefly from the saline parts, which are found in all matters, whether animal or vegetable, which we take either as food or physic. These little angular pungent bodies are fitter than others to penetrate even to the immediate organ, and to make themselves perceived there: we may judge of them by putting a grain of pure salt, of any kind whatever, upon the tongue, where it will make a very strong impression; and their analysis

discovers, that, of all mixed bodies, those that affect the organ most, are such as abound most in salts. See the article SALT.

TATIANITES, in church-history, Christian heretics in the second century; so called from their leader Tatian, a disciple of St. Justin.

This heresiarch took from Valentinus the fable of the Æons, and from Marcion the doctrine of two principles. But what particularly distinguished his followers was, their condemning of marriage, and forbidding the eating of flesh or drinking of wine.

TAT-TOO, q. d. TAP-TO, a beat of a drum at night, to advertise the soldiers to retreat or repair to their quarters in their garrison, or to their tents in a camp.

TAUGHT, or TAUT, in the sea-language, signifies the same as stiff, or fast: thus, to set taught the shrouds, or stays, is to make them more tight and stiff.

TAUNT, or TAUNT-MASTED, is said of a ship whose masts are too tall for her.

TAURUS, the bull, in zoology. See the article BULL.

TAURUS, in astronomy, the bull, one of the twelve signs of the zodiac, and the second in order.

The stars in the constellation Taurus, in Ptolemy's catalogue, are forty-four; in Tycho's, forty-one; and in the Britannic, a hundred thirty-five. The longitudes, latitudes, magnitudes, &c. are as follow:

Names and Situations of the Stars.

## Names and Situations of the Stars.

Preced. below the hyades ——— ———  
 In north. eye ——— ———

70.

Double one betwixt the nostril and S. eye ———

In the following shoulder ——— ——— ———

75.

80.

Middle, beneath the hyades ——— ———  
 South eye, pædicium, aldebaran ——— ———  
 In the following leg ——— ———

Preced. in the hind knee ——— ———

85.

Subseq. beneath hyades ——— ———

Subsequent in hind knee ——— ———

In root of north. horn ——— ———

90.

In root of south horn ——— ———

Preced. of 3 over south horn ——— ———

95.

More south in the south horn ——— ———

More north ——— ———

Middle of 3 over south horn ——— ———

In the middle of the horn ——— ———

100.

In extremity of north horn ——— ———

105.

Hindmost of 3 over south horn ——— ———

110.

Preced. of inform. foll. N. horn ——— ———

**TAWING**, the art of dressing skins in white, so as to be fit for divers manufactures, particularly gloves, &c.

All skins may be tawed; but those chiefly used for this purpose are lambs, sheep, kids, and goat-skins.

The method of tawing is this: having cleared the skins of wool or hair, by means of lime, &c. as described under the article **SHAMMY**, they are laid in a large vat of wood or stone, set on the ground full of water, in which quick-lime has been flaked, wherein they are allowed to lie a month or six weeks, according as the weather is more or less hot, or as the skins are required to be more or less soft and pliant.

While they are in the vat, the water and lime is changed twice, and the skins are taken out and put in again every day; and when they are taken out for the last time, they are laid all night to soak in a running water, to get out the greatest part of the lime; and in the morning are laid together by fixes one upon another, upon the wooden leg and are scraped stoutly one after another, to get the flesh off from the fleshy side, with a cutting two handled instrument called a knife, and then they cut off the legs (if they are not cut off before) and other superfluous parts about the extremes. Then they are laid in a vat or pit with a little water, where they

are filled with wooden pebbles for the space of a quarter of an hour, and then the vat is filled up with water, and they are rinsed in it.

In the next place, they are thrown on a clean pavement to drain, and afterwards cast into a fresh pit of water, out of which they rinse them well, and are laid again on the wooden leg, six at a time, with the hair-side outermost, over which they rub a kind of whetstone very briskly, to soften and fit them to receive four or five more preparations, given them on the leg, both on the flesh-side and the hair-side, with the knife, after the manner above mentioned.

After this they are put into a pit of water and wheaten-bran, and stirred about in it with wooden poles, till the bran is perceived to stick to them, and then they are left; as they rise of themselves to the top of the water by a kind of fermentation, they are plunged down again to the bottom, and at the same time fire is set to the liquor, which takes it as easily as if it were brandy, but goes out the moment the skins are all covered.

They repeat this operation as often as the skins rise above the water; and when they have done rising they take them out, lay them on the wooden leg, the fleshy-side outwards, and pass the knife over them to scrape off the bran.

Having thus cleared them of the bran, they lay the

# T A X

the skins in a large basket, and load them with huge stones to promote their draining: and when they have drained sufficiently, they give them their feeding, which is performed after the manner following:

For one hundred of large sheep-skins, and for smaller in proportion, they take eight pounds of alum, and three of sea-salt, and melt the whole with water in a vessel over the fire, pouring the dissolution out, while yet luke-warm, into a kind of trough, in which is twenty pounds of the finest wheat flour, with the yolks of eight dozen of eggs; of all which is formed a kind of paste, a little thicker than children's pap; which, when done, is put into another vessel, to be used in the following manner:

They pour a quantity of hot water into the trough in which the paste was prepared, mixing two spoonfuls of the paste with it; to do which they use a wooden spoon, which contains just as much as is required for a dozen of skins: and when the whole is well diluted, two dozen of the skins are plunged into it; but they take care that the water be not too hot, which would spoil the paste and burn the skins.

After they have lain some time in the trough, they take them out, one after another, with the hand, and stretch them out; this they do twice; and after they have given them all their paste, they put them into tubs, and there full them afresh with wooden pebbles.

Then they put them into a vat, where they are suffered to lie for five or six days, or more; then they take them out in fair weather, and hang them to dry on cords or racks, and the quicker they are dried the better; for if they be too long a drying, the salt and alum within them are apt to make them rise in a grain, which is an essential fault in this kind of dressing.

When the skins are dry, they are made up into bundles, and just dipt in fair water, and taken out and drained; and being thrown into an empty tub, and after having lain some time, are taken out and trampled under foot.

Then they draw them over a flat iron instrument, the top of which is round like a battledore, and the bottom fixed into a wooden block, to stretch and open them; and having been opened, they are hung in the air upon cords to dry: and being dry, they are opened a second time, by passing them again over the same instrument.

In the last place they are laid on a table, pulled out, and laid smooth, and are then fit for sale.

After the same manner are dressed horses, cows, calves skins, &c. for the sadlers or harness makers; as also those of dogs, wolves, bears, &c. except that in these they omit using the paste, salt and alum water being sufficient.

TAX, a tribute rated upon every town, which

# T E A

formerly was wont to be paid annually into the King's-Exchequer, but now not without consent of parliament; it differs from a subsidy in this, that it is always certain, as set down in the exchequer-book, and in general levied of every town, and not particularly of every man, &c. See the article **TRIBUTE**.

**TAXIS**, a term used by Vitruvius for what is now called ordonnance, being that which gives every part of a building its just dimensions with respect to its uses. See **ORDONNANCE**.

**TAXUS**, the yew-tree, in botany, an evergreen, which grows naturally in divers parts of England, and several other European countries: the wood is hard, reddish, veined, and very durable: the branches are spreading, and closely furnished with narrow, stiff, blunt-pointed leaves, of a very dark green colour: the flowers come out from the sides of the branches in clusters, and are male on some trees and female on others, neither have any cup or corolla, but consist of a gem, like a tetraphyllous perianthium: the stamina, in the male flowers, consist of a great number of filaments, joined at their bottoms in a column, and terminated with depressed antheræ: the pistillum of the female flower consists of an oval pointed germen, with a blunt stigma; and the fruit, when ripe, is of a red colour, soft, succulent, and open at the top, containing an oval oblong seed: the flowers come out at the latter end of May, and the berries are ripe in autumn.

The yew-tree is propagated by sowing its seeds when ripe: it is not so much raised now as formerly, when it was more in esteem; but as the fashion of clipped evergreens are now in disrepute, the principal use of these trees, at present, is to form hedges for the defence of tender plants, for which purpose it is the most proper of any: it is naturally of slow growth, and if planted among other evergreens, makes, with its dark green leaves, a fine contrast with those of a lighter colour. The seasons for removing these trees are either autumn or spring, according to the dryness or moisture of the soil.

This tree has great plenty of fibrous roots; therefore, by digging round them every year, and transplanting every third, will render them capable of being removed with the greater certainty of their growing, when they are got considerably large. There are many large yew-trees growing in several parts of England, the timber of which is greatly esteemed for many purposes.

**TEA**, *Thea*, in botany, a genus of plants, whose flower consists of six large, roundish, concave, equal petals, with a number of thread-like stamina; the fruit is a capsule formed of three globular bodies growing together, it contains three cells, each of which incloses a globose seed, internally angulated.

The tea plant is a shrub which grows to five or six

# TEA

six feet high, and is very ramose; its root is spreading and fibrous; the leaves are about an inch long and near half an inch broad, serrated on their edges, and terminating in a point. It is a native of China and Japan.

The dried leaves of this plant make a very considerable article of commerce; their taste is bitterish in a small degree, and slightly astringent; the smell is very agreeable, and by some is compared to that of new hay, or violets.

Tea is imported by variety of names, but it may principally be divided into three kinds, namely, the green, the imperial, and the bohea. The green is of several sorts, and is of various degrees of goodness, from the common coarse green tea to the hyson, which is now the dearest and accounted the best of all. The imperial tea is so called, because it is chiefly used by the emperor and great men in China and Japan: the leaf is large, and not so much-rolled up as in the other kinds; the colour is greenish, lively, and of a fine smell, with an agreeable taste. This, not many years ago, was in great request with us, but now we either have it not at all, or it is sold under a different name. The bohea is of a reddish brown, and the leaf is small, rolled up, and tinges the water of a brownish colour; but as the difference of taste of these teas are so well known, they therefore need not be insisted on.

Some authors assure us, there is no difference between the green and bohea teas but what arises from the manner of curing them; for the bohea is said to be higher dried, or rather burned, from which it receives its different taste and colour: they are all, however, the leaves of the same tree, and, perhaps, only differing according to the seasons when they are gathered.

The leaves being gathered, they are dried with great caution, partly by the help of air, and partly by heat; and, when thoroughly dried, will keep a long time fresh and good.

The common people of China put the tea into a vessel full of water, and boil it over a slow fire, where they keep it the whole day, and it serves for common drink.

The Japanese grind their tea to powder, and then put a spoonful of it into one of their cups, pouring hot water thereon, and then beating them up together with a brush till a foam arises thereon.

The Chinese pretend it is endowed with extraordinary virtues; such as cleansing the blood, curing the vertigo, easing pains in the head, and helping the dropy; however, it is certainly of some use in abating the acrimony of the humours, and in keeping people awake; but more especially in those who drink it but seldom.

Some physicians pretend that the Japanese, who drink it constantly, are never troubled with the stone or gravel; but we find no such effects in these parts. It is gently astringent, for which reason it

# TEL

hinders the water from weakening the stomach; and in those who take it but seldom, it will prevent the operation of a purge: it has indeed some power in preventing the gravel, but then it does not arise from the tea, for hot water alone will do the same. In general, it may be observed, that tea has contrary effects on different people; and, therefore, though it may be good for some constitutions, it is hurtful to others; for the good qualities of tea do not prevent its often doing harm: even in China, where its virtues are so vastly extolled, the people who drink it to great excess, are often thrown into diabetes, and die emaciated by it.

**TEARS**, *Lachryma*, a lymph or aqueous humour, which is subtile, limpid, and a little saltish: it is separated from the arterial blood by the lachrymal glands, and small glandulous grains on the inside of the eye-lids.

This fluid serves to moisten and deterge the eyes and the eye-lids, after which it tends to the internal angle of the eye, and is absorbed by the puncta lachrymalia, and conveyed to the lachrymal bag, from whence it goes into the nose, by the nasal canal. See the article **LACHRYMALIA**.

**TEASEL**, or **TEAZEL**, in botany. See the article **DIPSACUS**.

**TEBETH**, the tenth month of the Jewish ecclesiastical year, and fourth of the civil; answering to our month of December.

**TECHNICAL**, somewhat relating to arts or sciences; in this sense we say, technical terms, &c.

It is also particularly applied to a kind of verses, wherein are contained the rules or precepts of any art, thus digested to help the memory to retain them. See the article **MEMORY**.

**TE DEUM**, the name of a celebrated hymn, used in the Christian church, and so called because it begins with these words, *Te Deum laudamus*; We praise thee, O God.

It is sung in the Romish church with great pomp and solemnity, upon the gaining of a victory, or other happy event.

**TEETH**. See the article **TOOTH**.

**TELEPHIASTRUM**, in botany, a name by which Dillenius calls a species of portulaca. See the article **PORTULACA**.

**TELEPHIUM**, orpine, in botany, a genus of plants, whose flower consists of five oblong, obtuse, erect petals, which are narrowest at their base: the stamina are five subulated filaments, terminated with incumbent antheræ: the germen is three-cornered, acute, and crowned with three pointed spreading stigmas: the fruit is a short triquetrous capsule, having three valves and one cell, which contains many roundish seeds. See the article **ORPINE**.

**TELEPHOIDES**, in botany, Tournefort's name for a species of andrachne. See the article **ANDRACHNE**.

**TELESCOPE**, an optical instrument consisting of

of several lenses, by means of which, remote objects are so magnified as to appear nigh at hand. See LENS.

That the telescope is of a modern invention is most certain; neither does it appear that microscopes, or optic glasses of any kind, were known to the antients. It is contended that Alexander de Spina, a native of Pisa, was the first that made the use of glasses known to the world; but our countryman, friar Bacon, who died twenty one years before him, was, in all probability, acquainted with them first; for he wrote a book of perspective, in which he plainly shews that he did not only understand the nature of convex and concave glasses, but the use of them when combined in telescopes; though he no where in that treatise, discovers the manner in which they are to be put together. The telescope, with the concave eye-glass, was first invented by a mechanic of Middleburgh in Zealand, called Z. Johannides, about the year 1590, though J. Lipperhoy, another Dutchman, is candidate for the same discovery. From whence this sort of telescope is called *tubus batavus*.

Franciscus Fontana, a Neapolitan, contends, that he was the first contriver of the telescope composed of two convex glasses, which is now the common astronomical telescope; and Rheita pretends to be the first that rendered that telescope fit for terrestrial uses, by adding two eye-glasses to it.

The telescope is of two sorts, viz. dioptric or refracting; or cata-dioptric, by reflection and refraction conjointly.

*Dioptric or refracting TELESCOPE* consists of an object glass  $xx$  (plate LXXXVI. fig. 1.) by which the image  $fd$  of an object  $OB$ , at a distance, is formed in the focus  $e$  of the said glass, and in an inverted position. This image may be viewed by a single lens,  $ab$ , placed at its focal distance, as is usually done for viewing the heavenly bodies, because in them we do not regard the position: but for viewing objects near us, whose image we would have erect, we must for that purpose, add a second lens  $pq$ , at double its focal distance from the other, that the rays which come from  $ab$  may cross each other in the focus  $o$ , in order to erect the image  $gn$ , which it will form in its own focus  $m$ , because the rays come parallel from the lens  $ab$ . Lastly, a third lens  $ic$  is added to view the secondary image  $gn$ . These three lenses, or eye-glasses, are usually of the same size and focal length; and the power of magnifying is always as the focal length of the object-glass  $ew$  divided by the focal length of the eye glass  $lm$  or  $be$ : for instance, suppose  $ew = 10$  feet or 120 inches, and  $be$  or  $lm = 3$  inches; then will the object appear to the eye, through such a telescope, 40 times bigger than to the naked eye: and its surface will be magnified 1600 times, and its bulk or solidity 64000 times.

If instead of a convex eye-glass we should use a concave one of the same focal length, it would represent the object erect, equally magnified, and more distinct and bright; but the disadvantage of this glass is, that it admits but of a small area, or field of view, and, therefore, not to be used when we would see much of an object, or take in a great scope; but it is used to great advantage in viewing the planets and their satellites, Saturn's ring, Jupiter's belts, &c.

The magnifying power of a refracting telescope is thus estimated: let  $AB$  (fig. 2.) be the object-glass, and  $CD$  the eye-glass; and let  $HFI$  and  $GFM$  be two rays coming from the extreme parts of a distant object, and crossing each other in the center  $F$  of the glass  $AB$ . Then is the angle  $GFI = IFM$  that under which the object appears to the naked eye; but  $IE M = CKD$  is that under which the image appears as magnified by the eye-glass  $CD$ . But the angle  $IE M$  is to the angle  $IFM$ , as  $LE$  to  $LE$ , or as the focal distance of the object-glass to the focal distance of the eye-glass; and in that proportion is the object magnified.

There is a defect in all telescopes of this kind, not to be remedied by any means whatever, which was thought only to arise from hence, that spherical glasses do not collect rays to one and the same point; but it was happily discovered by Sir Isaac Newton, that the imperfection of this sort of telescope, so far as it arises from the spherical form of the glasses, bears almost no proportion to that which is owing to the different refrangibility of light. This diversity in refraction of the rays is about a twenty-eight part of the whole, so that the object glass of a telescope cannot collect the rays, which flow from any one point in the object, into a less room than the circular space whose diameter is about the fifty-sixth part of the breadth of the glass. Therefore since each point of the object will be represented in so large a space, and the centers of those spaces will be contiguous, because the points in the objects the rays flow from are so, it is evident that the image of an object made such by a glass must be a most confused representation, though it does not appear so when viewed through an eye-glass that magnifies in a moderate degree; consequently, the degree of magnifying in an eye-glass must not be too great with respect to that of the object-glass, lest the confusion become sensible. Notwithstanding, however, this imperfection, a dioptrical telescope may be made to magnify in any given degree, provided it be of sufficient length; for, the greater the focal distance of the object-glass is, the less may be the proportion which the focal distance of the eye-glass may bear to that of the object glass, without rendering the image obscure. Thus an object glass, whose focal distance is about four feet, will admit of an eye-glass whose focal distance shall be little

more than one inch, and, consequently, will magnify almost forty-eight times: but an object-glass of forty feet focus, will admit of an eye-glass of only four inch focus, and will therefore magnify 120 times; and an object-glass of an hundred feet focus, will admit of an eye-glass of little more than six inch focus, and will therefore magnify almost 200 times.

The reason of this disproportion, in their several degrees of magnifying, is to be explained in the following manner: since the diameters of the spaces, into which rays flowing from the several points of an object are collected, are as the breadth of the object-glass, it is evident that the degree of confuseness in the image is as the breadth of the glass (for the degree of confuseness will only be as the diameters or breadths of those spaces, and not as the spaces themselves.) Now the focal length of the eye-glass, that is, its power of magnifying, must be as that degree; for, if it exceeds it, it will render the confuseness sensible; and therefore must be as the breadth or diameter of the object-glass. The diameter of the object-glass, which is as the square root of its aperture or magnitude, must be as the square root of the power of magnifying in the telescope; for, unless the aperture itself be as the power of magnifying, the image will want light: the square root of the power of magnifying, will be as the square root of the focal distance of the object-glass; and therefore the focal distance of the eye-glass must be only as the square root of the object-glass. So that in making use of an object-glass of a longer focus, suppose than one that is given, you are not obliged to apply an eye-glass of a proportionably longer focus than what would suit the given object-glass, but such a one only whose focal distance shall be to the focal distance of that which will suit the given object-glass, as the square root of the focal length of the given one. And this is the reason that longer telescopes are capable of magnifying in a greater degree than shorter ones, without rendering the object confused or coloured.

*Cata-dioptric, or reflecting* TELESCOPE, is the most noble and useful of all others; the mechanism of which is as follows:

ABEH (fig. 3.) is the large tube, or body of the instrument, in which BE is a large reflecting mirror, with a hole in the middle CD. This mirror receives the rays  $a, b, d$ , coming from the object at a distance, and reflects them converging to its focus  $e$ , where they cross each other, and form the inverted image IM;  $xy$  is a small concave mirror, whose focus is at  $f$ , at a small distance from the image. By this means the rays coming from the image are reflected back through the central hole CD of the large mirror, where they fall on the plano convex lens WX, and are by it converged to a focus, and there form a second image RS, very

large and erect, which is viewed by a meniscus eye-glass YZ, by the eye at P, through a very small hole in the end of the eye-piece YCDZ.

If the first lens WX were taken away, the image would be formed somewhat larger at MI; but the area or scope would be less, and therefore the view not so pleasant. At TV is placed a circular piece of brass, with a hole of a proper size to circumscribe the image, and cut off all superfluous or extraneous rays, that so the object may appear as distinct as possible.

As the image is formed by reflection, the rays of every sort will be united nearly in one point, and will therefore admit of an eye-glass YZ of a deep charge, or small focal distance; and so the power of magnifying will be proportionally increased.

The magnifying power of a reflecting telescope is thus computed. The parallel rays KB (fig. 4.) and LE are reflected by the large object speculum AF to its focus  $a$ , where the image IM is formed; which image is defined by two other rays NQ, PQ, coming from the extreme parts of the object at a remote distance, and meeting in the center of the large speculum at Q. Now if  $f$  be the focus of the small mirror GH, supposing the image were formed in the said focus  $f$  (that is, that both the foci  $a$  and  $f$  were coincident) then the rays proceeding from the image IM will proceed parallel after reflection, and produce distinct vision of the image, which will then subtend an angle IOM at the center O of the speculum GH, which is to the angle IQM, under which the object appears to the naked eye, as  $aQ$  to  $aO$  or  $fO$ . So that the magnifying power would in this case be as  $\frac{aQ}{fO}$ .

But, to increase this magnifying power, the image IM is not placed in the focus of the small speculum, but at a small distance beyond it; by which means the rays coming from the image to the speculum GH will be reflected converging to a distant focus R, where a secondary large image IM is formed from the first image IM; which image is seen under the same angle IOM with the former from the center of the speculum GH: but from the center of the eye-glass TV it is seen under the large angle ISM. But the angle ISM is to the angle IOM as OR to SR; wherefore the second ratio, or part of the magnifying power, is that of  $\frac{OR}{SR}$ .

Consequently the whole magnifying power of the telescope is  $\frac{aQ}{aO} \times \frac{OR}{SR}$  (because in this case  $fO$  becomes  $aO$ .) Or, in other words, the angle NQP, under which the object appears to the naked eye, is to the angle ISM, under which the large magnified secondary image IM appears to the eye through the eye-glass, as  $\frac{aQ \times OR}{aO \times SR}$ . Such is the theory of the

telescope

telescope first contrived by Dr. J. Gregory, and therefore called the Gregorian telescope; but it received its last improvement from the late Mr. Halley, and is now in common use.

A small alteration was made in the structure of this telescope by Mr. Cassegrain, viz: in using a convex speculum *GH* (fig. 4.) instead of the concave one *GH*. Now, if they are equally spherical, that is, if they are segments of the same sphere, then will *f* be also the virtual focus of the convex *GH*; and, if all other things remain the same, the first image *IM* will be virtually the same as before, and the last image *IM* will be really the same; so that the magnifying power of this form of the telescope is  $\frac{aQ \times OR}{aO \times SR}$ , which is equal to that of Gregory's form.

Sir Isaac Newton ordered this telescope to be made in a different form or manner, as follows: *ABCD* (fig. 5.) was a large octagonal tube, or case; *EF* a large polished speculum, whose focus is at *o*; *GH* a plane speculum truly centered, and fixed at half a right-angle with the axis of the large one. Then parallel rays *aE*, *bF*, incident on the large speculum *EF*, instead of being reflected to the focus *o*, were intercepted by the small plane speculum *GH*, and by it reflected towards a hole *cd* in the side of the tube, crossing each other in the point *O*, which is now the true focal point; and from thence they proceed to an eye-glass *ef* placed in that hole, whose focal distance is very small, and therefore the power of magnifying may be very great in this form of the telescope; because the image *IM* is made by one reflection (for that of the plane speculum only alters the course of the rays, and adds nothing to the confusion of the image) and will, for that reason, bear being viewed by a glass of a very deep charge, in comparison of an image formed by differently refrangible rays.

This telescope is a very good one, as to its effect or performance, but it is not so commodious for common use as those of the Gregorian form, and is therefore now pretty much laid aside. They who would see a larger account hereof may consult Sir Isaac's Optics, and several Philosophical Transactions, where he describes it at large, and the reasons which induced him to make choice of this structure rather than that of Dr. Gregory: or see a compendious account of the whole in the last edition of Dr. Gregory's Elements of Optics.

*Aerial Telescope*, is a dioptric telescope used without a tube, in a dark night; for the use of the tube is not only to direct the glasses, but also to make the place dark where the images of objects are formed.

Huygenius contrived a telescope of this kind for viewing the celestial bodies, by fixing the object-glass on the top of a long upright pole, and direct-

ing its axis towards any object by means of a silk line coming from the object-glass to the eye-glass below.

**TELLER**, an officer of the Exchequer, in ancient records called tallier; there are four of these officers, whose duty is to receive all sums due to the king, and to give the clerk of the pells a bill to charge him therewith.

They likewise pay all money due from the king, by warrant from the auditor of the receipt, and make weekly and yearly books, both of their receipts and payments, which they deliver to the lord-treasurer.

**TEMPERAMENT**, among physicians, denotes the same with constitution; or a certain habitude of the humours of the human body, whereby it may be denominated hot, cold, moist, dry, bilious, sanguine, phlegmatic, melancholic, &c.

According to Boerhaave, moistening, diluting, and tempering substances, are a proper diet for persons of a hot and acrid temperament; and, on the contrary, all heating things are prejudicial to them: whereas, in persons of a cold and moist habit, just the reverse of this obtains. To persons of a sanguineous temperament, evacuating and tempering medicines are beneficial, and heating or drastic stimulating things pernicious. Persons of a melancholy temperament, are greatly injured by hot, drying, and acrid substances; whereas moistening, refrigerating, relaxing, emollient substances, and such as gently dissolve without acrimony, are beneficial to them. See **CONSTITUTION**.

**TEMPERAMENT**, in music, is the rectifying or mending the imperfect concords, by transferring to them part of the beauties of the perfect ones. See **CONCORD** and **INTERVAL**.

**TEMPERING** of *Steel and Iron*, the rendering them either more compact and hard, or soft and pliant, according as the different uses for which they are wanted may require.

To harden and temper English, Flemish, and Swedish steel, they must have a pretty high heat given them, and then be suddenly quenched in water to make them hard; but Spanish and Venetian steel will require no more than a blood-red heat before it is quenched.

If the steel be too hard or brittle for an edged tool, &c. take it down by rubbing a piece of grindstone or whetstone hard upon the work, to take off the black scurf; then brighten or heat it in the fire, and as it grows hotter, you will see the colour change by degrees, coming first to a straw or light gold-colour, then to a darker gold-colour, and at last to a blue-colour.

Choose such of these colours as the work requires, then quench it suddenly in the water. The light gold-colour is for files, cold chisels, and punches to punch iron and steel: the dark gold-colour, for punches to use on brass, &c. and the blue-colour

gives the temper for springs. The tempering of files and needles is performed after a peculiar manner. See the article **STEEL**.

**TEMPLARS**, or **TEMPLERS**, a religious order instituted at Jerusalem, about the year 1118.

Some religious gentlemen put themselves under the government of the patriarch of Jerusalem, renounced property, made the vow of celibacy and obedience, and lived like canons regular. King Baldwin assigned them an apartment in his palace. They had likewise lands given them by the king, the patriarch, and the nobility, for their maintenance.

At first there were but nine of this order, and the two principal persons were Hugo de Paganis, and Geoffroy of St. Omers. About nine years after their institution, a rule was drawn up for them, and a white habit assigned them, by pope Honorius II. About twenty years afterwards, in the popedom of Eugenius III. they had red crosses sewed upon their cloaks, as a mark of distinction; and in a short time they were increased to about three hundred, in their convent at Jerusalem.

They took the name of Knights Templars, because their first house stood near the temple dedicated to our Saviour, at Jerusalem.

This order, after having performed many great exploits against the infidels, became rich and powerful all over Europe; but the knights, abusing their wealth and credit, fell into great disorders and irregularities. Many crimes and enormities being alleged against them, they were prosecuted in France, Italy, and Spain; and at last, the pope, by his bull of the 22d of May, 1312, given in the council of Vienna, pronounced the extinction of the order of Templars, and united their estates to the order of St. John of Jerusalem.

**TEMPLE**, a general name for places of public worship, whether Pagan, Christian, or otherwise.

But the word, in a restrained sense, is used to denote the places, or edifices, in which the pagans offered sacrifice to their false gods. Thus we hear of the Temples of Jupiter, Apollo, Bacchus, &c.

**TEMPLES**, in anatomy, a double part of the head, reaching from the forehead and eyes to the two ears.

**TEMPORAL**, a term generally used for secular, as a distinction from ecclesiastical. Thus we say, temporal lords, and spiritual or ecclesiastical lords.

**TEMPORALITIES**, the temporal revenues of an ecclesiastic, such as have been annexed to bishops fees by kings and other great personages of this land, as they are barons or lords of parliament, such as manors, lands, and lay-fees.

**TENAILLE**, in fortification, a kind of out-work, resembling a horn-work, but generally somewhat different, for instead of two demi-bastions, it bears only in front a re-entering angle betwixt the

same wings without flanks; and the sides are parallel. See the articles **FORTIFICATION** and **HORN-WORK**.

**TENANT**, one that holds lands or tenements of some lord, or land, by rent, fealty, &c.

**TENCH**, in ichthyology, the English name of a species of the cyprinus, of a purplish black colour, with an even tail; its length is generally about ten or eleven inches, its breadth about three, and its thickness more than two; but it sometimes grows to an immoderate large size.

**TENDER**, in law, signifies carefully to offer, or circumspectly endeavour the performance of a thing; as, to tender rent, is to offer it at the time and place when and where it ought to be paid, which is done to save the penalty of a bond or obligation, before action is brought thereon.

**TENDER**, a small ship, in the service of men of war, for carrying of men, provisions, or any thing else that is necessary.

**TENDONS**, are white, firm, and tenacious parts, continuous to the muscles, and usually forming their extremities. When the fibres, of which they are composed, expand themselves into a membrane, they are called Aponeuroses. See the article **MUSCLE**.

**TENEMENT**, properly signifies a house; but in a larger sense, it is taken for any house, land, rent, or other thing, which a person holds of another.

**TENESMUS**, in medicine, a name given by medical writers, to a complaint which is a continual desire of going to stool, but without any stool being ready to be voided.

Signs of it are a titillation and itching about the anus, attended with a violent burning pain, and a desire of compressing and voiding something, and this attended usually with no excrement, or only a pulposus or mucous matter, and very often a falling down of the rectum.

The causes of a tenesmus are, the ascarides, a small sort of worms, which usually infest the rectum, and occasion a continual itching and tickling there; the abuse of refinous purging medicines; much riding will also sometimes occasion it. See **PROLAPSUS**, **HÆMORRHOID**, &c.

As the tenesmus is merely a symptomatic disease, the primary disorder is first to be examined, and treated in order to a cure; thus, when it is occasioned by ascarides, worm medicines are to be given, and clysters of a proper kind injected; and when the worms are by this means destroyed, the tenesmus, which was no more than a symptom, naturally ceases. In general, the regimen and method of cure in a tenesmus, are the same with those prescribed in a dysentery; great relief is afforded by a fomentation of warm milk, in which elder-flowers have been boiled, as also by a clyster of mutton broth,

broth, or an emollient clyster, in which earth-worms have been boiled. In a tenesmus, the last refuge is to opiates. See DYSENTERY.

TENET, or TENENT, a particular opinion, dogma, or doctrine, professed by some divine, philosopher, &c.

TENON, in building, &c. the square end of a piece of wood, or metal, diminished by one-third of its thickness, to be received into a hole in another piece, called a mortise, for the jointing or fastening the two together.

It is made in various forms, square, dove-tailed for double mortises, and the like.

TENOR, or TENOUR, the purport or content of a writing or instrument in law, &c.

TENOR, or TENORE, in music, the first mean or middle part, or that which is the ordinary pitch of the voice, when neither raised to a treble, or lowered to a bass. See BARITONO.

TENOR, or TENORISTA, is also used for a person who sings the tenor part in concert also, for any instrument proper to play it.

TENSE, time, in grammar, an inflection of verbs, whereby they are made to signify or distinguish the circumstance of time, in what they affirm. See VERB.

There are only three simple tenses, or times; the present, as *amo, I love*; the preterit, as *amavi, I have loved*; and the future, as *amabo, I shall or will love*. See PRESENT, &c.

But, as in the preterit, one may say, that the thing is but just now done; or, indefinitely, that it was done; hence, in most languages, there are two sorts of preterits, or past tenses; the one definite, which marks the thing to be precisely done, as *I have said, I have done, I have dined*; the other signifies it done indeterminately, and is for that reason called indefinite, or aorist, as *I wrote, I went*, &c. See the articles AORIST, IMPERFECT, PLUS-QUAMPERFECT, &c.

TENT, in surgery, a roll of lint worked into the shape of a nail, with a broad flat head.

Tents differ in thickness and length, according to the size of the wound for which they are intended.

TENTER, a machine used in the cloth manufacture, to stretch out the pieces of cloth, stuff, &c. or only to make them even, and set them square.

TENURE, in law, signifies the manner whereby lands or tenements are held, or the service that the tenant owes to his lord: it likewise denotes the estate in the land.

TEPID, a term used by writers on mineral waters, &c. to express such of them as have a less sensible cold than common water. See the article MINERAL WATERS.

TEREBINTHUS, the turpentine-tree. See the article TURPENTINE.

TERES, in anatomy, a name given to two muscles of the arm; one is called *teres major*, and

is one of the depressor muscles, which has its origin at the lower angle of the scapula, and its termination three fingers below the head of the humerus: the other is called *teres minor*, being one of the abductor-muscles, and having its origin at the inferior costa of the scapula; this, together with the *infraspinatus*, properly forms one conjunct muscle, having at the extremity, only a single tendon, which is inserted into the posterior part of the neck of the humerus.

TERGIFCETUS PLANTS, such as bear their seeds on the backside of their leaves: such are all the capillary plants.

TERM, *Terminus*, in general, signifies much the same with boundary, or limit.

TERM, in law, is generally taken for a limitation of time or estate; as a lease for a term of life or years, which is deemed a chattel real. See the article CHATTEL.

Term, however, is more particularly used for that time wherein our courts of justice are open; in opposition to which, the rest of the year is called vacation.

TERMS of an Equation, in algebra, are the several names or members, of which it is composed, and such as have the same unknown letter, but in different powers or degrees: for if the same unknown letter be found in several members in the same degree or power, they shall pass but for one term.

TERMS of Proportion, in mathematics, are such numbers, letters, or quantities, as are compared one with another.

Thus, if  $2.4::8:16$  then  $a.b::c.d$ , then  $a, b, c, d$ , or 2, 4, 8, 16, are called the terms;  $a$  being the first term,  $b$  the second term, &c.

TERMS, or COURSES, in medicine, the menses, or womens monthly purgations. See the article MENSES.

TERRACE, in gardening, a bank of earth raised to a proper elevation, whereby the prospect of the adjacent country may be more enlarged. When terraces are rightly situated, they are great ornaments, for their regularity and opening, especially when they are well made, and their ascent not too steep.

TERRACE is also applied to the roofs of houses that are flat, and whereon one may walk; as also to balconies that project.

TERRAQUEOUS, in geography, an appellation given to our globe, because consisting of land and water.

TERRE-PLEIN, in fortification, denotes the horizontal superficies, or top, of the rampart, between the inferior talus and the banquette. It is thus called, as lying nearly level, with only a little slope inwardly, to bear the recoil of the cannon.

TERRE-TENANT, in law, the person who hath the

the actual possession of the land: thus, if a freeholder lets out his freehold to another, to be possessed and occupied by him, this person is called the *terre-tenant*.

**TERRELLA**, *μικρον*, an appellation given to a load-stone, when turned into a spherical figure, and is placed so, that its poles and equator, &c. correspond to the poles and equator of the world; as being a just representation of the great magnetical globe which we inhabit. See the article **MAGNET**.

Such a *terrella*, if nicely poised and placed in a meridian, it was imagined, would turn about its axis once in twenty-four hours; but experience has shewed this to be a mistake.

**TERRESTRIAL**, something partaking of the nature of earth: thus we say, the terrestrial globe, line, &c.

**TERRITORY**, in geography, denotes an extent or compass of land, within the bounds, or belonging to the jurisdiction, of any state, city, or other subdivision of a country.

**TERTIAN**, in medicine, an ague, or intermitting fever, the fits of which return every third day: that is, there are two fits in three days, the day intervening being without any fit at all.

**TESSELATED PAVEMENTS**, those of rich mosaic work, made of curious square marbles, bricks, or tiles, called *tesellæ*, from their resembling dice.

**TEST**, in metallurgy, a vessel of the nature of the coppel, used for large quantities of metals at once.

**TEST LIQUOR**, a liquor used by dealers in brandies, to prove whether they be genuine, or mixed with home-spirits.

**TESTACEOUS**, in natural history, an epithet given to a species of fish, which are covered with a strong thick shell, as tortoises, oysters, pearl-fish, &c.

**TESTAMENT**, *Testamentum*, in law, a solemn and authentic act, whereby a person declares his will, as to the disposal of his estate, effects, burial, &c. See the article **WILL**.

There are two sorts of testaments, viz. one in writing, and one in words; which last is called a nuncupative testament, or will: but this is not good in case of lands, which are only deviseable by a testament in writing, executed in the life-time of the testator.

**TESTATOR**, or **TESTATRIX**, the person who makes his or her will and testament.

**TESTATUM**, in law, a writ in personal actions, where, if the defendant cannot be arrested on a *capias*, in the county where the action is laid, but is returned non est inventus by the sheriff, this writ shall be sent into any other county, where such a person is thought to be, or have where-withal to satisfy the demand.

**TESTICLE**, *Testis*, in anatomy, a double part in male animals, serving for generation. See the article **GENERATION**.

**TESTICULATED**, among botanists, an appellation given to roots composed of two tuberosc knobs, resembling testicles; such are those of orchis, &c.

**TESTIMONIAL**, a kind of certificate, signed either by the master and a fellow of the college where the person last resided; or by three, at least, reverend divines, who knew him well for three years last past, giving an account of the virtues, uniformity, and learning of the person.

Testimonial is also a certificate, under the hand of a justice of the peace, testifying the place and time when a soldier, or mariner landed, and the place of his dwelling, &c. whither he is to pass.

There is also another kind of testimonial for the clergy, made by persons present, that a clergyman has in all things complied with the act of uniformity; and to certify, that the clerk has performed what the law requires on his institution and induction.

**TESTUDO**, in zoology, a genus of amphibious animals, with four legs and a tail, and the body covered with a firm shell.

This genus comprehends all those animals known in English by the names of tortoises and turtles; of which there are a great many species, some with four toes on each foot; others with five toes on the fore feet, and four on the hinder ones; and others, distinguished by other peculiarities, particularly the compartments of their shells, some being divided into irregular spaces, and others beautifully tessellated. See plate LXXXV. fig. 4.

The Americans find so good account in catching turtle, that they make themselves very expert at it: they watch them from their nests on shore, in moonlight lights; and, before they reach the sea, turn them on their backs, and leave them till morning; when they are sure to find them, since they are utterly unable to recover their former posture: at other times they hunt them in boats, with a peculiar kind of spear, striking them with it through the shell; and as there is a cord fastened to the spear, they are taken much in the same manner as the whales. See the article **FISHERY**.

**TESTUDO**, in antiquity, was particularly used among the poets, &c. for the ancient lyre; by reason it was originally made by its inventor, Mercury, of the black or hollow shell of the *testudo aquatica*, or sea-tortoise, which he accidentally found on the banks of the river Nile.

**TESTUDO**, in the military art of the ancients, was a kind of cover or screen which the soldiers, e. gr. a whole company, made themselves of their bucklers, by holding them up over their heads, and standing close to each other. This expedient served to shelter them from darts, stones, &c. thrown

Fig. 5.

thrown upon them, especially those thrown from above, when they went to the assault.

**TESTUDO** was also a kind of large wooden tower which moved on several wheels, and was covered with bullocks hides flead, serving to shelter the soldiers when they approached the walls to mine them, or to batter them with rams.

**TETANUS**, in medicine, is a convulsive motion that makes any part rigid and inflexible. See **CONVULSION**.

**TETHYS**, in ichthyology, a genus of fish of the order of the zoophytæ, the body of which is formed as it were of two lips of an oblong cartilaginous body; between them are four tentacula, which have the form of ears, and two perforations in most species near the tentacula.

**TETRACERA**, in botany, a genus of plants, whose flower is hexapetalous, with a persistent cup formed of six roundish patent leaves, which are alternately smaller; it contains a great number of permanent stamina, and four ovate germina, which afterwards become so many reflexed capsules, each opening by a suture in the upper part, and containing one cell, which incloses a roundish seed. There is but one species of this genus, which is a native of the West-Indies, its flowers are produced in spikes, and the leaves resemble those of the bay tree.

**TETRACHORD**, in the ancient music, a concord consisting of four degrees or intervals, and four terms or sounds; called also by the antients diatessarion, and by us a fourth.

This interval had the name tetrachord given it, with respect to the lyre and its chords or strings.

**TETRADECARHOMBIS**, in natural history, the name of a genus of fossils, of the class of the selenitæ, expressing a rhomboidal body, consisting of fourteen planes. See **SELENITÆ**.

The characters of this genus are, that the bodies of it are exactly of the same form with the common selenitæ; but that in these each of the end-planes is divided into two, and there are, by this means, eight of these planes instead of four. Of this genus there are only three known species.

**TETRADIAPASON**, a musical chord, otherwise called a quadruple diapason, or eighth.

**TETRADITÆ**, a name given to several different sects of heretics. The sabbathians were called tetraditæ, from their keeping Easter-day on the fourth day, or on Wednesday. The manichees, and others who admitted of a quaternity instead of a trinity in the Godhead, were also called tetraditæ. The followers of Petrus Fullensis had the same appellation, by reason of the addition they made to the trisagion, to support an error they held, that in our Saviour's passion it was not any particular person of the Godhead that suffered, but the whole Deity.

**TETRADYNAMIA**, in botany, the name of the fifteenth class of plants in Linnæus's system:

this class consists of such plants as bear hermaphrodite flowers, and furnished with six stamina, two of which are shorter than the rest, by which circumstance they are distinguished from those of the hexadria class. The general characters are these; the calyx is an oblong perianthium, composed of four leaves, which are ovato-oblong, concave, obtuse; connivent, gibbous at the base, the opposite ones equal, and deciduous; this cup is properly a nectarium, which is the reason of the base being gibbous; the corolla is called cruciform, it consists of four equal petals which have ungues somewhat longer than the cup, these are erect and flatly subululated; the petals are broad at the top, obtuse, and the sides hardly touching each other, the insertion of the petals is in the same circle with the stamina. The filaments are subulate, and six in number; of which two that are opposite are of the length of the cup, the other four are somewhat longer, but not so long as the corolla; the antheræ are oblong and pointed, thicker at the base, and erect, with the tops bending outwards; the nectariferous glandule, which in different genera has various appearances, is usually placed near the filaments, and particularly to the two shorter ones, to whose base it is fastened; these two filaments have a light curvature to prevent their pressing upon the glandule, which is the reason they become shorter than the others; the germen of the pistillum is placed above the receptacle, and is every day in its growth raised higher and higher; the style in some genera is wanting, but those plants as have it are of the length of or longer than the stamina; the stigma is always obtuse; the fruit, or pericarpium, is a bivalvular pod, which often contains two cells; this, when ripe, opens by splitting from the apex to the base; and it has always a little membranaceous substance, serving within as a septum, when the pod is bilocular; this projects beyond the apex, and is the rudiments of what was the style. The seeds are roundish, inclining downwards, alternately plunged lengthways into the dissepiment, and immersed in the sutures of the pericarpium.

This class of plants is truly natural, and has been received as such under whatever name by all the systematic writers on botany, and includes the cruciformes of Tournefort, and silicoles and siliculosæ plants of Ray.

The plants in general belonging to this class are held to be antiscorbutic and diuretic; the taste in most is watery, mixed with a sharpness, but they commonly loose their virtues when dried.

To this genus of plants belong the feurvy-grass, mithridate-mustard, cabbage, turnep, radish, stock-gilliflower; with several other genera.

**TETRAEDRON**, or **TETRAHEDRON**, in geometry, one of the five regular or Platonic bodies or solids, comprehended under four equilateral and equal triangles. See plate LXXXVI. fig. 6.

It is demonstrated by mathematicians, that the square of the side of a tetraedron is to the square of the diameter of a sphere, wherein it may be inscribed, in a subequalateral ratio: whence it follows, that the side of a tetraedron is to the diameter of a sphere it is inscribed in, as  $\sqrt{2}$  to the  $\sqrt{3}$ , consequently they are incommensurable.

**TETRAGON**, in geometry, a general name for any four-sided figure, as a square, parallelogram, rhombus, or trapezium.

**TETRAGONIA**, in botany, a genus of plants, whose flower is destitute of a corolla; the cup is permanent and coloured, and formed of four oval plane diflexed leaves, and contains about twenty capillary filaments, which are terminated with oblong incumbent antheræ: the fruit is a coriaceous crust, with four angles, each having a longitudinal wing or border, and contains four cells, each inclosing a single osceous seed, which includes four oblong kernels.

The species belonging to this plant are natives of the cape of Good-Hope.

**TETRAGONOTHECA**, in botany, a genus of plants, whose flower is compound and radiated, being formed of hermaphrodite and female corollulæ; the hermaphrodite, which compose the disc, are numerous and funnel-shaped, and the radius is formed of twelve ligulated female florets, which have their extremities cut into three equal acute segments; the receptacle is paleaceous, and the seeds are solitary, roundish, and without any down.

**TETRAGRAMMATON**, a denomination given by the Greeks to the Hebrew name of God, Jehovah, because consisting of four letters.

**TETRAGYNIA**, in botany, the name of an order or subdivision in the Linnæan system, and is applied to those plants whose flowers have in each four pistils or female parts of generation. See the article **BOTANY**.

**TETRAMETER**, in ancient poetry, an iambic verse, consisting of four measures, or eight feet. This kind of verse is only found in the comic poets, as Terence, &c.

**TETRANDRIA**, in botany, the name of the fourth class in the Linnæan system; it comprehends all those plants whose flowers are hermaphrodite and furnished with four equal stamina, or male parts, in each. To this class belong the teasel, scabious, madder, plantain, holly, with several other genera.

**TETRAO**, in ornithology, a genus of birds, of the order of the gallinæ, distinguished by having the part of the forehead over the eyes naked and papillose.

This genus comprehends the urogallus major, or wood-cock; the urogallus minor, or growle; the moor-cock, lagopus, &c.

**TETRAHEDRON**, or **TETRAEDRON**. See **TETRAEDRON**.

**TETRAPETALOUS FLOWERS**, among botanists, are those whose corolla consists of four petals; such compose the class tetradynamia. See the article **TETRADYNAMIA**.

**TETRAPHARMACUM**, signifies any remedy consisting of four ingredients.

**TETRAPLA**, in church history, a bible disposed by Origen under four columns, in each whereof was a different Greek version, viz. that of Aquila, that of Symmachus, that of the Seventy, and that of Theodotion. See **IBLE**.

**TETRAPTERA**, in the history of insects, a name given to that order of insects, which have four wings.

**TETRAPTOTE**, *Tetraptoton*, in grammar, a name given to such defective nouns as have only four cases; such are *viciis*, *pecudis*, *sordis*, &c. as being deprived of the nominative and vocative singular.

**TETRAPYRAMIDIA**, in natural history, the name of a genus of spars, influenced in their shape by an admixture of particles of tin, and found in form of broad-bottomed pyramids of four sides. See the article **SPAR**.

Of this genus there is only one known species, which is usually of a brownish colour, and found in Saxony, as also in Devonshire, Cornwall, and other counties of England, where there is tin.

**TETRARCH**, *Tetrarcha*, a prince who holds and governs a fourth part of a kingdom. Such originally was the import of the title tetrarch; but it was afterwards applied to any petty king or sovereign, and became synonymous with ethnarch.

**TETRASTITCH**, a stanza, epigram, or poem, consisting of four verses.

**TETRASTYLE**, in the ancient architecture, a building, and particularly a temple, with four columns in its front.

**TETRASYLLABICAL**, a word consisting of four syllables.

**TETRATONON**, in music, a name whereby the superfluous fifth is sometimes called, as containing four tones.

**TEUCRIUM**, germander, in botany, a genus of plants, whose flower is monopetalous and ringent, the tube of which is cylindric and short, the upper-lip is erect and deeply divided into two acute segments, and the lower-lip is spreading and trifid, the lateral segments are like those of the upper one, but the middle one is large and roundish; there is no pericarpium, but the seeds, which are roundish and four in number, are lodged in the bottom of the cup.

To this genus Linnæus has added the polium chamædrys and chamæpitys of Tournefort, with the scordium and marum syriacum of other authors.

The lesser creeping germander is accounted splenetic, hepatic, and diuretic, and good in intentions where deterging is wanted; it is also accounted

counted an alexipharmic, and has been reckoned as a specific against the gout.

**TEUTONIC**, something belonging to the Teutons, an ancient people of Germany, inhabiting chiefly along the coasts of the German ocean: thus, the Teutonic language is the ancient language of Germany, which is ranked among the mother tongues. The Teutonic is now called the German or Dutch, and is distinguished into upper and lower. The upper has two notable dialects, viz. 1. The Scandian, Danish, or perhaps Gothic; to which belong the languages spoken in Denmark, Norway, Sweden, and Iceland. 2. The Saxon, to which belong the several languages of the English, Scots, Frisian, and those on the north of the Elbe. To the lower belong the Low Dutch, Flemish, &c. spoken through the Netherlands, &c.

**TEUTONIC ORDER**, a military order of knights, established towards the close of the twelfth century, and thus called, as chiefly consisting of Germans or Teutons.

**TEXT**, a relative term, contradistinguished to gloss or commentary, and signifying an original discourse exclusive of any note or interpretation. This word is particularly used for a certain passage of scripture, chosen by a preacher to be the subject of his sermon.

**TEXTUARIES**, *Textuarii*, a name given the sect of the Caraites among the Jews. See the article **CARAITES**.

**TEXTURE**, *Textura*, properly denotes the arrangement and cohesion of several slender bodies or threads interwoven or entangled among each other, as in the webs of spiders, or in cloths, stuffs, &c.

Texture is also used in speaking of any union or constituent particles of a concrete body, whether by weaving, hooking, knitting, tying, chaining, indenting, intruding, compressing, attracting, or any other way. In which sense we say a close compact texture, a lax porous texture, a regular or irregular texture, &c. A great deal depends on the texture of the component parts of a body; hence most of its particular properties, its specific gravity, colour, &c.

**THALAMI nervorum opticorum**, in anatomy, two oblong prominences of the lateral ventricles of the brain, medullary without, but a little cineritious within, being thus called because the optic nerves rise out of them.

**THALIA**, in botany, a genus of plants, whose characters are not perfectly known; the cup is a perianthium, the corolla consists of five ovato-oblong petals, which are waved and concave; the stamina consists of a single filament with the antheræ not described; the germen is egg-shaped, and the fruit is an ovate unilocular drupe, containing an osseous nut with two cells.

This is the same with the cortusa of Plumier.

**THALICTRUM**, meadow-rue, in botany, a genus of plants, whose flower consists of four roundish, obtuse, concave, deciduous petals, with a great number of filaments, broad and compressed towards their tops, and terminated with oblong erect antheræ; there is no pericarpium, but the germina, which are numerous and collected in a head, becomes each a furrowed, ovate, and mutilated seed.

The common meadow-rue grows in moist places and by the sides of brooks in several parts of England. The stalks rise about five or six feet high, and are stiff, furrowed, branched, hollow, and generally of a reddish colour; the leaves are large, of a shining green, and divided into several jaggs, and the flowers grow on the tops of the branches. The root purges like rhubarb, tinging the urine with a yellow colour, and is said to have the same qualities in all respects except the quantity, which must be three times as much; and the juice of the leaves and flowers is accounted good for internal bleedings.

**THANE**, or **THAIN**, *Thanus*, a name of an ancient dignity among the English and Scots, or Anglo-Saxons.

Skene makes thane to be a dignity equal to the son of an earl. Camden will have it, that thanes were only dignified by the offices they bore. There were two kinds or orders of thanes; the king's thanes, and the ordinary thanes: the first were those who attended the king in his courts, and who held lands immediately of the king. The ordinary thanes, or the thani minores, were the lords of the manors, who had particular jurisdiction within their limits, and over their own tenants; these changed their names for that of barons, and hence their courts are called courts baron to this day.

**THANE-LANDS**, were lands granted by charters of our ancient kings, to their thanes, with all immunities, except the three-fold necessity of expedition, repair of castles, and mending bridges.

**THAPSIA**, deadly-carrot, in botany, a genus of umbelliferous plants, the general corolla of which is uniform: the proper flowers consist each of five lanceolated incurved petals, with the same number of capillary stamina: the fruit is oblong, surrounded longitudinally with a membrane, and separable into two parts, each consisting of a large oblong convex seed, pointed at each end, having on each side a plane border, which is large, undivided, and emarginated at the top and bottom.

This plant is used to provoke the menses, and other evacuations; and externally it is used in ointments for the itch, and the like cutaneous disorders.

**THAWING**, the resolution of ice into its former fluid state, by the warmth of the air, &c. See **FREEZING**.

Boerhaave observes, that if a sudden thaw takes place after a long sharp frost, which has bound up the rivers, and penetrated the earth's surface to a considerable depth, it is, usually, quickly succeeded by a multitude of clouds and uncommon heats, and then by thunder and lightening. The reason is, that the fat vapours and exhalations raised by the subterraneous heat, have long remained imprisoned under that covering of the earth, as appears hence, that if the ice of a ditch be broke in the middle of a severe frost, it presently emits warm vapours, and this the more plentifully, as well as the hotter, by how much the frost is harder and the ice thicker. As soon, therefore, as the exterior frozen turf of earth is softened by warmth, the pent-up vapours immediately escape through all the passages they can find, and mounting on high, form clouds, which being driven about, and sometimes illumined by the sun, produce such effects. Hence, these violent thunders in Muscovy, Sweden, and Denmark, after a thaw.

**THEA**, the tea-tree, in botany. See the article **TEA**.

**THEATINES**, a religious order in the Romish church, so called from their principal founder John Peter Caraffa, then bishop of Theate, or Chiete, in the kingdom of Naples, and afterwards pope, under the name of Paul IV. The names of the other founders were Gaetan, Boniface, and Configlieri.

These four pious men desiring to reform the ecclesiastical state, laid the foundation of an order of regular clerks at Rome, in the year 1524. Pope Clement VII. approved the institute, and permitted the brethren to make the three religious vows, to elect a superior every three years, and to draw up statutes for the regulation of the order.

They first endeavoured, by their example, to revive, among the clergy, the poverty of the apostles and first disciples of our Saviour, and were the first who assumed the title of regular clerks.

**THEATRE**, *θεατρον*, in antiquity, a public edifice for the exhibiting of scenic spectacles, or shews, to the people; comprehending not only the eminence on which the actors appeared, and the action passed, but also the whole area of the place, common to the actors and spectators. See the articles **DRAMA**, **PLAY**, &c.

**THEATRE**, is also used, in architecture, chiefly among the Italians, for an assemblage of several buildings, which, by a happy disposition and elevation, represents an agreeable scene to the eye.

**Anatomical THEATRE**, in a school of medicine and surgery, is a hall, with several rows of seats, disposed in the circumference of an amphitheatre; having a table bearing on a pivot, in the middle, for the dissection of bodies.

**THEBAID**, *Theabais*, a celebrated heroic poem of Statius, the subject whereof is the civil war of

Thebes, between the two brothers, Eteocles and Polynices; or, Thebes taken by Thebians.

**THEFT**, *Furtum*, in law, an unlawful felonious taking away another man's moveable and personal goods, against the owner's will, with intent to steal them.

It is divided into theft, or larceny, properly so called, and petit theft, or petit larceny; the former whereof is of goods above the value of 12*d.* and is deemed felony; the other, which is of goods under that value, is not felony. See the articles **FELONY** and **LARCENY**.

**THELIGONUM**, in botany, a genus producing male and female flowers on the same plant, neither having any corolla: the male flower consists of a monophyllous turbinate cup, divided into two revolved segments, and contains a number of erect stamina: the female flower consists of a small, erect, bifid cup, containing a globose germen, which turns to a coriaceous, round, unilocular capsule, which incloses a globose seed.

This is the same with the cynocrambe of Tournefort.

**THEME**, in matters of education, denotes the subject of an exercise, for young students to write or compose on.

**THENAR**, in anatomy, the abductor-muscle of the thumb; it has its origin in the transverse ligament that joins the bones of the carpus, and its termination in the first and second phalanx; the two sesamoid bones of the thumb are usually found lodged in the tendon of this muscle.

**THENAR**, is also the abductor-muscle of the great-toe; it has its origin from the internal side of the calcaneum, and the os naviculare; and its termination at the internal side of the great toe, beside the internal sesamoid bone.

**THEOBROMA**, in botany, a genus of plants, whose flower consists of a triphyllous cup, and five gibbous concave petals, each of them armed with a bifid seta, divided like two horns; the nectarium is bell-shaped and erecto-patent; the filaments are numerous, and joined in five bodies, and topped with roundish antheræ: the fruit is a woody cortex of an unequal surface, with five ridges opening in five cells, each containing several fleshy seeds of almost an oval figure.

This genus includes the cacao of Tournefort, and the guazuma of Plumier; the former of which has an oblong quinquangular fruit, lengthened at each extremity, containing the seeds of which the chocolate is made. See **CACAO** and **CHOCOLATE**.

The guazuma has a subglobose fruit, covered with rough tubercles, and its bark perforated in the manner of a sieve. They are all natives of the West-Indies.

**THEODOLITE**, a mathematical instrument much used in surveying, for the taking of angles, distances, &c.

It is made variously, several persons having their several ways of contriving it, each more simple and portable, more accurate and expeditious than others. The common one consists of a brass circle about a foot diameter, cut in the form represented in plate LXXXVII. fig. 1. having its limb divided into 360 degrees, and each degree subdivided either diagonally, or otherwise, into minutes.

Underneath, at *cc*, are fixed two little pillars *bb* (fig. 2.) which support an axis, whereupon is fixed a telescope consisting of two glasses, in a square brass tube, for the viewing of remote objects.

On the center of the circle moves the index *C*, which is a circular plate, having a compass in the middle whose meridian line answers to the fiducial line *aa*: at *bb*, are fixed two pillars to support an axis which bears a telescope like the former, whose line of collimation answers to the fiducial line *aa*. At each end of either telescope, is fixed a plain sight for the viewing nearer objects.

The ends of the index *aa* are cut circularly, to fit the divisions of the limb *B*; and when that limb is diagonally divided, the fiducial line at one end of the index shews the degrees and minutes upon the limb. The whole instrument is mounted with a ball and socket, upon a three-legged staff.

Most theodolites have no telescopes, but only four plain sights, two of them fastened on the limb, and two on the ends of the index.

Mr. Sisson's improved theodolite being one of the best of these instruments, we shall here give its description, fig. 3. The three staves, whereby it is supported, screw into bell-metal joints by brass-ferrils at top, which are moveable between brass-pillars fixed in a strong brass-plate; in which, round the center, is fixed a socket with a ball moveable in it, and upon which the four screws press that set the limb horizontal. Next above is such another plate, through which the said screws pass, and on which, round the center, is fixed a frustum of a cone of bell-metal, whose axis, being connected with the center of the ball, is always perpendicular to the limb, by means of a conical brass ferril fitted to it, whereon is fixed the compass-box, and on it the limb, which is a strong bell-metal ring, whereon are moveable three brass indexes, in whose plate are fixed four brass-pillars, that joining at top hold the center-pin of the bell-metal double sextant, whose double index is fixed in the center of the same plate. Within the double sextant is fixed the spirit-level, and over it the telescope. See the article LEVEL.

The compass box is graved with two diamonds for north and south, and with 20 degrees on both sides of each, that the needle may be set to the variation, and its error also known.

The limb has two fleur-de-luces against the diamonds in the box, and is curiously divided into whole degrees, and numbered to the left hand at

every 10° to twice 180°, having three indexes (with Nonius's divisions on each for the decimals of a degree) that are moved by a pinion fixed below one of them without moving the limb, and in another is a screw and spring under, to fix it to any part of the limb: it has also divisions numbered for taking the quarter girt in round timber; to which a shorter index is used, having Nonius's divisions for the decimals of an inch; but an abatement must be made for the bark, if not taken off. See RULE.

The double sextant is divided on one side from under its center (when the spirit tube and telescope are level) to above 60 degrees each way, and numbered at 10, 20, &c. And the double index (through which it is moveable) shews on the same side the degree and decimal of any altitude, or depression to that extent, by Nonius's divisions; on the other side are divisions numbered for taking the upright height of timber, &c. in feet, when distant ten feet, which at 20 must be doubled, and at 30 trebled; and also the quantities for reducing hypotenusal lines to horizontal: it is moveable by a pinion fixed in the double index.

The telescope is a little shorter than the diameter of the limb, that a fall may not hurt it; yet it will magnify as much, and shew a distinct object as perfect, as most of treble its length: in its focus are very fine cross wires, whose intersection is in the plane of the double sextant, and this was a whole circle, and turned in a lathe to a true plane, and is fixed at right angles to the limb; so that whenever the limb is set horizontal (which is readily done by making the spirit-tube level over two screws, and the like over the other two) the double sextant and telescope are moveable in a vertical plane, and then every angle taken on the limb (though the telescope be never so much elevated or depressed) will be an angle in the plane of the horizon, and this is absolutely necessary in the plotting an horizontal plane.

**THEOGONY**, that branch of the heathen theology, which taught the genealogy of their gods.

**THEOLOGY**, or **DIVINITY**, a science which instructs us in the knowledge of God or divine things; or which has God, and the things he has revealed, for its object. See the article GOD.

Hence theology may be distinguished into natural, which comprehends the knowledge we have of God from his works, by the light of reason alone; and supernatural, which contains what we are taught concerning God in revelation.

Theology is again distinguished into positive, moral, and scholastic. Positive theology is the knowledge of the holy scriptures, and of the signification thereof, conformably to the opinions of the fathers and councils, without the assistance of any argumentation. Some will have it that this ought to be called expositive, rather than positive.

Moral theology, is that which teaches us the divine laws relating to our manners and actions. Scholastic, or school theology, is that which proceeds by reasoning; or that derives the knowledge of several divine things from certain established principles of faith.

**THEOPHRASTA**, in botany, a genus of plants, whose flower is monopetalous, campanulated, and divided at the edge into five obtuse segments, and contains five subulated stamina; the fruit is a large globose unilocular capsule, containing many roundish seeds.

This genus comprehends the Eresia of Plumier.

**THEORBA**, **THIORBA**, or **TIORBA**, a musical instrument made in form of a large lute, except that it has two necks or juga, the second and longer whereof sustains the four last rows of chords which are to give the deepest sounds.

**THEOREM**, a speculative proposition, demonstrating the properties of any subject.

Theorems are either universal, which extend to any quantity, without restriction universally; as this, that the rectangle of the sum, and difference of any two quantities, is equal to the difference of their squares: or particular, which extend only to a particular quantity; as this, in an equilateral right-lined triangle, each of the angles is 60 degrees.

**THEORETIC**, or **THEORETICAL**, something relating to theory, or that terminates in speculation.

**THEORY**, in general, denotes any doctrine which terminates in speculation alone without considering the practical uses and application thereof.

**THERAPEUTÆ**, a term applied to those who are wholly employed in the service of religion. This general term has been applied to particular sects of men, concerning whom there have been great disputes among the learned.

**THERAPEUTICE**, **THERAPEUTICS**, that part of medicine which acquaints us with the rules that are to be observed, and the medicines to be employed in the cure of diseases.

**THERAPHIM**, or **TERAPHIM**, certain images, or superstitious figures mentioned in scripture. Some Jewish writers tell us, the theraphim were effigies of human heads, placed in niches, and consulted as oracles. Others say, they were talismans, or figures of metal, cast and engraved under certain aspects of the planets; to which they ascribed extraordinary effects. All the eastern people are much addicted to this superstition; and the Persians still call them *telesin*, a name nearly approaching to theraphim.

The learned Spencer makes the word theraphim to be the same as seraphim, by change of the S into T: whence it follows, that these images were representations of these angels called seraphim. M. Jurien supposes them to have been a sort of dii-pe-ates, or household gods.

**THERMOMETER**, an instrument for measuring the increase and decrease of the heat and cold of the air, by means of the elastic and expansive power of bodies of the fluid sort.

Many different ways, methods, and forms of constructing such an useful instrument have been thought of, and invented at several times for this purpose; at first air, then oil, then spirits of wine, and lastly, quicksilver, have been every way attempted and tortured in this experiment.

The spring of air, being sooner affected by heat and cold than that of any other fluid, was first thought upon as the best expedient to answer this end; and so it really would be, were it not that the weight or pressure of the atmosphere affects it also at the same time; and by acting sometimes with, sometimes against it, renders the effect by heat or cold very uncertain, and, therefore, the instrument useless. For example: the air in the bottle AF (plate LXXXVII. fig. 2.) will, by its expansion, when the air grows warmer, raise the water higher in the tube than the point H; and if the air be lighter at this time, it will press less on the surface of the water as H, and so will suffer it to rise still higher. But if the air be heavier, it will act against the spring, and not permit it to raise the water so high. The same may be observed with respect to its contraction by cold; wherefore such an instrument, for common or constant use, will not do at all, though, perhaps, none is better calculated for some extemporaneous uses, as measuring the degree of coldness in different cellars, or of warmth in divers rooms upon the same floor.

It was upon this account found necessary to have recourse to some other fluid, which, secured from the pressure of the air in a tube, hermitically sealed, might expand and contract solely by the heat and coldness of the air about it. And because most fluids are subject to freeze or thicken in great degrees of cold, it was soon considered that spirits of wine, a little tinged with cochineal, would best answer the purpose, and accordingly thermometers were generally made therewith, and became of common use.

Though the spirit of wine thermometers would do very well to shew the comparative heat of the air, yet this was far short of the virtuoso's views, who wanted to explore the various and vastly different degrees of heat in other bodies, as boiling water, boiling oils, melted metals, and even fire itself, and degrees of cold too, beyond what the spirit thermometer can shew. For spirit in a moderate degree of heat will burst the tube; and in an intense degree of cold will freeze, as the French philosophers found, who went to measure a degree upon the surface of the earth under the north polar circle. It having been found by experiment, that linseed oil required four times the degree of heat to make it boil as water did, it was quickly substituted  
instead

instead of spirits for philosophic uses. This Sir Isaac Newton always used, and by it discovered the comparative degree of heat which makes water boil, which melts wax, which makes spirit of wine boil, and melts tin and lead; beyond which we do not find the oil thermometer has been applied; for which reason (as also for its fupplying the tube) it has been less used of late.

The mercurial thermometer, which will sustain any degree of heat or cold, as far as any instrument of this kind can be expected to do, was invented by Mr. Farenheit, of Amsterdam; and though several artificers made them as well as he, yet they still go by his name. Dr. Boerhaave used only this thermometer. As the mercury very freely and uniformly expands itself from hard frost to the heat of summer, so one sort of those thermometers are contrived with a scale, to include those extremes only, and the beginning of the divisions, or 0, is fixed to that altitude of the quicksilver, as is observed when water just begins to freeze, or snow to thaw; for which reason that is called the freezing point in the scale. This thermometer is small, short, put in a neat frame, and carried in the pocket any where.

But the grand thermometer of Farenheit is graduated after a different manner, as destined to a more critical and extensive use. In this the bulb, or large part at the bottom, is not spherical, as in common ones, but cylindrical; to the end, that the heat may penetrate and reach the inmost parts as soon as possible, so that the whole may expand uniformly together. Hence it is, that in the cylindrical bulb the fluid will expand and rise immediately, whereas in the spherical bulb it is seen first to fall (by the sudden expansion of the ball, before the fluid when heated) and then to rise, by the expansion of the fluid when heated. We have given a figure, both of Farenheit's mercurial thermometer, and also of Sir Isaac Newton's made with linseed oil. See plate LXXXVII. fig. 2.

Sir Isaac's seems to be the best fitted of any for a standard weather thermometer; and even for any degree of heat which the various states of the human body exhibit; and also for those different degrees which vegetation requires in the green-house, hot-bed, &c. In all which cases it is necessary there should be one common, unerring, and universal measure, or standard, which at all times, and at every place, will shew the same degree of heat, by the same expansion of the fluid, according to which the scale should be made in every standard thermometer. In order to this, the tube proposed should be very nicely weighed, when empty, and then the bulb, and about a tenth part of the length of the tube above it, is to be filled with quicksilver; then it is to be weighed again, and the excess of this, above the former weight, will give the weight of the quicksilver poured in; this will give the weight of

the 100th part. Let a mark be made with a file upon the tube at the surface of the inclosed quicksilver.

Then weigh out nine or ten parcels of quicksilver, each equal to a hundredth part of that first put into the tube, and having poured the several parcels in, one after another, upon the inclosed quicksilver, and marked the tube successively at the surface of each parcel, you will have the tube divided into proper intervals, which, if the bore of the tube be every where the same, will be equal to each other; if not, they will be unequal; and each of these intervals is to be divided into ten others, increasing or decreasing as the intervals do.

When this is done, the capacity of the tube is divided into thousandth parts of that of the ball, and the contiguous part of the tube reaching up to the first mark. The tube is now to be put into a frame, and by the side of it is to be placed a scale, divided into thousandth parts, exactly corresponding to those on the tube; and writing 1000 over-against the first mark, you write 1010 over-against the second, 1020 against the third, and so on, as you see in the figure.

The standard thermometer-tube, and its scale, being thus constructed, is then to be filled with some proper fluid, as linseed-oil, where great degrees of heat are not proposed; and mercury is to be used, when they are. When the fluid is poured in, it is to be adjusted in such a quantity, that it may stand just at the principal point, marked 1000, in water just freezing. And here great precaution is to be used; for many trials must determine this point, to which the fluid must always rise by slow degrees, and with an uniform motion.

When this point is well secured, all the trouble is over, the ball, being then immersed in boiling water, spirits, oils, melted metals, &c. in snow, freezing mixtures, &c. the expansions, by all the various degrees of heat and cold, will be shewn by the number against the heights to which the fluid rises in the tube, in each case, these are to be wrote on the side of the scale; and, since the same degree of heat will cause the same expansion of the same fluid at all times, it is evident, if thermometers were every where constructed in this manner, the observations made by them in any part of the world, may be compared together, which cannot otherwise be done; whence, this part of philosophy would receive its final perfection.

By one of those standard thermometers, well made, many more might soon be constructed with any expanding fluid, without the trouble of graduating their tubes by equal quantities of quicksilver. For having filled the balls, and a convenient part of the tube, with the proposed fluid, place them all together in a vessel of cold water; and while it is warming as gently as possible, when the oil in the standard-thermometer shall arise successively at the several

several divisions of its scale, at the same instant of time mark the new tubes at the several heights of their fluids, and form a scale for every tube that shall correspond to those marks. Then, while the liquors subside, by cooling gently, examine whether they nicely agree at the several marks.

To determine the freezing point in all, they are to stand together in the water till it just begins to freeze: or, having all the other points duly, that may be deduced very exactly by the rule of proportion.

A thermometer that shall vary very sensibly by every small variation of heat and cold, as those of the atmosphere, must have a large ball in proportion to the bore of the tube; and, that the heat or cold may sooner penetrate the innermost parts of the liquor, the ball should not be spherical, but oblong and flatted like a French flask; and the lengths of the tubes should be proportioned to the degrees of heat they are intended to discover.

Sir Isaac Newton graduated his standard-thermometer on both sides. Those on the right-hand measured the heat of the oil; as those on the left, measured the bulk thereof: but since the latter, as well as the former, begins from a cypher at the freezing point, and is regularly continued upwards by the common divisions 10, 20, 30, 40, &c. it will equally serve both purposes; since the degree of heat will always be proportioned to the expansion of the bulk of the fluid above or below the freezing point.

**THERMOSCOPE**, an instrument shewing the changes happening in the air with respect to heat and cold.

The word thermoscope is generally used indifferently with that of thermometer, though there is some difference in the literal import of the two; the first signifying an instrument that shews, or exhibits, the changes of heat, &c. to the eye; and the latter an instrument that measures those changes; on which foundation the thermometer should be a more accurate thermoscope, &c.

This difference the excellent Wolfius taking hold of, describes all the thermometers in use as thermoscopes; shewing that none of them properly measures the heat, &c. none of them do more than indicate the same. Though their different heights, yesterday and to-day, shew a difference of heat, yet, since they do not discover the ratio of yesterday's heat to to-day's, they are not strictly thermometers.

**THESIS**, a general position which a person advances, and offers to maintain.

In colleges it is frequent to have placards, containing a number of them, in theology, in medicine, in philosophy, in law, &c.

**THESIUM**, in botany, a genus of plants, whose corolla is wanting; the flower consists of a monophyllous, turbinated, coloured cup, which is per-

sistent, and divided at the edge into five erect, obtuse, semi-lanceolated segments: the stamina consists of five subulated filaments, inserted in the base of the lacinæ of the cup, and topped with roundish antheræ: the pistil is single; and the seed, which is roundish and single, is contained in the bottom of the cup.

**THIGH**, *Femur*, in anatomy, that part of the body of men, quadrupeds, and birds, between the leg and the trunk. See **FEMUR**.

**THIMBLE**, an instrument made of brass, silver, iron, &c. put on the finger to thrust a needle thro' any cloth, silk, &c. used by all seamstresses, tailors, &c.

**THINKING**, a general name for any act or operation of the mind. See **MIND**.

Chauvinus, with the Cartesians, will have thinking to consist in a certain native inherent motion or agitation of the human mind, whereof itself is conscious; for they conceive it to be no other than the very essence of the mind itself, or at least its principal and essential property. All the materials of thinking are, by Mr. Locke, derived from the two sources of sensation and reflection.

The school-philosophers usually divide thinking into intellectual and volitive. Intellectual is subdivided into perception, judgment, reasoning, and method. Volitive thinking, or volition, admits of infinite different modifications, or new determinations.

The doctrine of the Cartesians, who maintain that thinking is essential to the human soul, and that there is no time when the soul does not think, is overturned by Mr. Locke, who shews, that in sleep without dreaming, there is an entire cessation of all the modes of thinking.

**THIRD**, in music, a concord resulting from a mixture of two sounds, containing an interval of two degrees.

**THISTLE**, *Carduus*, in botany. See the article **CARDUUS**.

*Fullers-THISTLE*. See **DIPSACUS**.

*Globe-THISTLE*. See **ECHINOPS**.

*Golden-THISTLE*. See **SCOLYMUS**.

*Holy-THISTLE*. See **CARDUUS BENEDICTUS**.

*Melon-THISTLE*. See **CACTUS**.

*Sow-THISTLE*. See **SONCHUS**.

*Torch-THISTLE*. See **CEREUS**.

*Order of the THISTLE*, or of **St. Andrew**, a military order of knighthood in Scotland, the rise and institution whereof is variously related by different authors: Lesley, bishop of Ross, reports, that the night before the battle between Athelstan king of Northumberland, and Hungus king of the Picts, a bright cross, in form of that whereon St. Andrew (the tutelar saint of Scotland) suffered martyrdom, appeared to Hungus, who having gained the victory, ever after bore the figure of that cross on his banners. Others assert, that Achaius

king of Scotland, first instituted this order, after having made the famous league offensive and defensive with Charlemagne king of France. But although the thistle had been acknowledged as the symbol of the kingdom of Scotland from the reign of Achaius, yet some refer the beginning of this order to the reign of Charles VII. of France. Others place the foundation of it as low as the year 1500.

The chief and principal ensign is a gold collar, composed of thistles and sprigs of rue, interlinked with amulets of gold, having pendant thereunto the image of St. Andrew with his cross, and this motto, NEMO ME IMPUNE LACESSET.

THLASPI, treacle mustard, in botany, a genus of plants, producing cruciform flowers; the petals are oval, double the length of the cup, having narrow unguis; the stamina are six filaments, two of which are shorter than the rest, and topped with acuminate antheræ: the fruit consists of a compressed heart-shaped pod, with an emarginated border, containing two cells, which include several seeds affixed to a furture.

There are several species belonging to this genus, among which is included the bursa pastoris, or shepherd's pouch.

The wild thlaspi, which grows naturally in several parts of England, is said to promote urine, and to dissolve coagulated blood; and the seeds are an ingredient in the mithridate and Venice-treacle. See the article SINAPIS.

THLIPSIS, *Θλίψις*, a compression of the stomach from food, which is offensive only by its quantity, and not endued with any remarkable quality; or from a conflux of humours, void of acrimony, into the part.

THOMÆANS, THOMEANS, THOMISTS, or *Christians of St. THOMAS*, a people of the East-Indies, who, according to tradition, received the Gospel from St. Thomas.

Upon the arrival of the Portuguese at Calicut, in their first voyage to the Indies, they met with ancient Christians, who pretended to be descended from those converted by St. Thomas.

St. THOMAS's Day, a festival of the Christian church, observed on December 21, in commemoration of St. Thomas the Apostle.

THOMISM, or THOMAISM, the doctrine of St. Thomas Aquinas, and his followers the Thomists, chiefly with regard to predestination and grace.

THOMISTS, a sect of school-divines, who maintain Thomism. See the preceding article.

THORACIC, *Thoracicus*, a name given to two branches of the axillary artery, on account of their conveying the blood into some parts of the thorax. See the article THORAX.

The thoracic arteries are distinguished into upper and lower. There are likewise thoracic veins, up-

per and under, destined for the conveyance of the blood from the thorax to the axillary vein.

THORACIC DUCT, or CHYLIFEROUS DUCT, a very slender canal, receiving the chyle from the chyliferous vessels, and the lymph from the lymphatics, and carrying them to the thorax, and usually through it to the subclavian vein.

The beginning of this duct is in the reservoir or receptaculum chyli, which is situated in the left side of the upper vertebra of the loins, under the aorta, and vessels of the left kidney; the rest of the duct has some resemblance of a sack or bag, and is larger and more irregular in its figure. Its end is usually in the subclavian vein; sometimes in the jugular. In dogs, and many other animals, its progress is under the aorta; but in the human body it ascends along the right side of the vertebra of the back, and passes between the aorta and the vena azygos, sometimes with a simple trunk, sometimes divided into two: its breadth, where divided, is about that of a wheat straw.

The best manner of demonstrating it in animals, is to feed a dog well, and then to strangle him; and as soon as the body is opened, to tie it up with a thread in the breast, just by the subclavian; by this means, the cistern, or receptacle of the chyle, and the chyliferous vessels and lymphatics, are all exposed evidently to view at once.

In a human body, they may also be observed any time after death, by injecting, according to Salzman, wax, or any fluid, or indeed only by inflating the great lymphatic vessel, which runs by the left emulgent vein; or, otherwise, if, according to Henninger, an injection, or barely an inflation, be made into a lacteal of the second order, to be traced out in the middle of the mesentery; or, finally, if the pleura be carefully cut between the aorta and the vena azygos, the duct will usually be easily found there.

It is composed of a fine, thin, and pellucid membrane, and within it there are valves, as in the lacteals and lymphatics, which prevent the reflux of the chyle. There are more of these in the human body than in beasts; and, finally, there is a semilunar valve, closing its extremity under the subclavian.

The use of the thoracic duct is to carry the chyle to the blood, through the thorax, as it receives it from the receptacle, and with it the lymph from the lymphatics.

THORAX, in anatomy, that large part of the body situated between the abdomen and the neck.

The parts of the thorax are of two kinds, the continent, or containing, and contained: the continent parts, or those which form the cavity, are either common or proper; the common continent parts of the thorax are the cuticula, the cutis and the pinguello.

The continent parts proper or peculiar to the thorax,

thorax; are these; the breasts, the pectoral muscles, the intercostals, the diaphragm, the pleura, and, finally, the bones; of these last there are twenty-four ribs, the sternum, and twelve vertebræ.

The contents of the cavity formed by these, or the parts contained in the thorax, are the mediastinum, the lungs, the heart and its pericardium, with the large vessels arising from it, particularly the trunks of the aorta, and the pulmonary artery of the vena cava and pulmonary vein, the thoracic duct, and, finally, the greater part of the œsophagus.

The uses of the parts of the thorax in general, are their serving to respiration and the circulation of the blood, in both sexes; and, in women, to the producing milk.

**THORN-APPLE**, in botany. See the article **DATURA**.

**THORNBACK**, in ichthyology, the prickly raia, with tuberculose teeth, and a transverse cartilage in the belly.

**THOUGHT**, or sentiment, a general name for all the ideas consequent on the operations of the mind, and even for the operations themselves.

**THRASHING**, or **THRESHING**, *Flagellatio*, in agriculture, the art of beating the corn out of the ears.

**THRAVE**, or **THREAVE** of *Corn*, twenty-four sheaves, or four shocks of six sheaves to the shock; though, in some countries, they only reckon twelve shocks to the thrave.

**THREE**, *Rule of*. See the article **RULE**.

**THRENODY**, *Threnodia*, a mournful or funeral song.

**THRIFT**, *statice*, in botany. See the article **STATICE**.

**THROAT**, the anterior part of an animal, between the head and the shoulders, wherein is the gullet.

**THROAT**, in architecture, fortification, &c. See the article **GORGE**.

**THRONE**, *θρονος*, a royal seat, or chair of state, enriched with ornaments of architecture and sculpture, made of some precious matter, raised on one or more steps, and covered with a kind of canopy. Such are the thrones in the rooms of audience of kings, and other sovereigns.

**THROWSTER**, one who prepares raw silk for the weavers, by cleansing and twisting it.

**THRUSH**, in ornithology, two species of *turdus*, the one called the common thrush, and the other the missel-thrush.

The common thrush is the *turdus* with a white line over the eyes. This is smaller than the field-fare; the head is small and flatted; the eyes are bright, their iris hazle; the ears patulous; the beak about half an inch long, brown and pointed; the head and back of an olive brown, spotted with a dark colour; the breast is yellow, the belly whitish, and the legs brown.

The other species of *turdus*, called the missel-thrush, is of a greyish yellow colour with a spotted breast, being the largest of the *turdus* kind.

**THRYALLIS**, in botany, a genus of plants, whose flower consists of five roundish patent petals, with ten subulated filaments topped with roundish antheræ; the germen is obtuse, supporting a slender pointal; and the fruit is a three-cornered, triangular, obtuse capsule, opening into three parts, and contains a single, ovate, and very smooth seed.

**THUMB**, *Pollex*, in anatomy, one of the parts or extremities of the hand. See **HAND**.

**THUMMIM**, in the scripture-learning. See **URIM** and **THUMMIM**.

**THUNDER**, a noise in the regions of the air, excited by a sudden kindling of sulphureous exhalations.

Those philosophers who maintain, that vapours are buoyed up in the air by particles of fire adhering to them, account for the phenomena of thunder and lightning in the following manner; they suppose that from the particles of sulphur, nitre, and other combustible matter, which are exhaled from the earth, and carried into the higher regions of the atmosphere, together with the ascending vapours, is formed an inflammable substance, which, when a sufficient quantity of fiery particles is separated from the vapours, by the collision of two clouds, or otherwise, takes fire, and shoots out into a train of light, greater or less, according to the strength and quantity of the materials. This opinion is certainly false; for it is impossible the vapours should be attended with such fiery particles as is here supposed: neither have we occasion to fly to such an hypothesis; for as vapours, exhaled from the surface of the water, are carried up into the atmosphere, in like manner the effluvia of solid bodies are continually ascending thither. Now we find by experience, that there are several inflammable bodies, which, being mixed together in due proportion, will kindle into flame by fermentation alone, without the help of any fiery particles.

Thus, M. Lemery having covered up, in the earth, about fifty pounds of a mixture, composed of equal parts of sulphur and filings of iron, tempered with water; after eight or nine hours time the earth, where it was laid, vomited up flames. Thus also, mix a small quantity of gun-powder with oil of cloves, pour gently upon this mixture two or three times as much spirit of nitre, and you will observe a bright inflammation suddenly arising from it. A mixture of the two fluids alone will take fire, the powder is added only to augment the inflammation. When, therefore, there happens to be a mixture of the effluvia of such bodies floating in the air, they ferment, kindle, and, flashing like gun-powder, occasion those explosions and streams of fire, which we call thunder and lightning.

As to the particular species of the effluvia, which

compose this mixture, that cannot be exactly determined: they are thought to be chiefly sulphureous and nitrous; sulphureous, because of the sulphureous smell which lightning generally leaves behind, and of that sultry heat in the air, which is commonly the forerunner of it; nitrous, because we do not know of any body liable to so sudden and violent an explosion as nitre is.

Dr. Lister is of opinion, that the matter both of thunder and lightning, and also of earthquakes, is the effluvia of the pyrites; as he does, that the matter of volcanos is the pyrites itself. This is a mineral that emits copious exhalations, and is exceeding apt to take fire upon the admission of moisture. See the doctor's defence of his notion in the *Phil. Trans.* No. 157. He thinks this may be the reason why England is so little troubled with earthquakes, and Italy, and almost all places round the Mediterranean sea, so very much, viz. because the pyrites are rarely found in England; and, where they are, they lie very thin, in comparison of what they do in those countries; as the vast quantity of sulphur emitted from the burning mountains there, seems to shew.

The effects of thunder and lightning are owing to the sudden and violent agitation the air is put into thereby, together with the force of the explosion; and not to thunderbolts falling from the clouds, as is supposed by the vulgar.

Some are inclined to think, that thunderbolts are artificial, and that they were applied by the ancients to some use. What confirms them in their opinion is, that they are found more frequently where sepulchres have been, than in other places.

The distance the thunder is from us, may nearly be estimated by the interval of time between our seeing the lightning, and hearing the thunder; for as the motion of light is so very quick, that the time it takes up in coming to us from the cloud, is not perceptible; and as that of a sound is about a thousand feet in a second; allowing a thousand feet for every second that passes between our seeing the one, and hearing the other, we have the distance of the cloud, pretty nearly, from whence the thunder comes.

**THUNDERING LEGION**, *Legio Fulminans*, was a legion in the Roman army, consisting of Christian soldiers, who, in the expedition of the emperor Marcus Aurelius against the Sarmatæ, Quadi, and Marcomanni, saved the whole army then ready to perish of thirst, by procuring, with their prayers, a very plentiful shower thereon, and at the same time a furious hail, mixed with lightning and thunderbolts, on the enemy.

This is the account commonly given by ecclesiastical historians, and the whole history is engraven in bas-relievs on the Antonine column. And hence arose the denomination Thunderers, though

some say, that the legion, those Christians were of, was called the Thundering legion before.

**THURSDAY**, the fifth day of the Christian week, but the sixth day of that of the Jews.

*Holy THURSDAY*, the same with ascension-day. See the article **ASCENSION**.

*Maunday-THURSDAY*. See the article **MAUNDAY-THURDAY**.

**THUJA**, the *Arbor Vitæ*, in botany; this tree is evergreen, and has a strong woody trunk, which rises to the height of forty feet or more; the bark, while young, is smooth, and of a dark brown colour; but as the tree advances in growth, the bark becomes cracked and less smooth; the branches are produced irregularly on every side, standing almost horizontal; and the young slender shoots frequently hang downward; the principal branches stand but thin, and the young branches, which are flat, are mostly furnished with leaves; these are small, and lay over each other in an imbricated manner. The flowers are produced from the sides of the young branches, and are male and female; the male flowers grow in oblong catkins, they have no petals, but contain in each four stamina, which are scarce visible; the female flowers are collected into a common and almost oval cone, which is formed of a number of scales, two flowers standing opposite in each scale. The fruit is an ovato-oblong obtuse cone, opening longitudinally, having obtuse smooth scales, containing one or two oblong seeds, having a membranaceous wing.

This kind is a native of Canada, Siberia, and other northern countries; it flowers early in the spring, and the seeds ripen in September.

Another sort, which grows naturally in the northern parts of China where it rises to a considerable height, hath its branches growing more close and compact together than those of the common sort, and is better furnished with leaves, which are brighter and have a more elegant appearance, and is therefore held in greater esteem with us than the former. The leaves of these plants have a rank oily smell when bruised, particularly the first mentioned; they are propagated by seeds, layers, or cuttings; if from seeds (which produce the best plants) they should be sown soon after they are ripe, which is in the spring; if from layers or cuttings, September is the best time, and the succeeding autumn they will be fit for transplanting into the nursery, where they may remain till of a proper size for planting, where they are intended to remain for good.

**THYMBRA**, mountain hyssop, in botany, a genus of plants, whose flower is monopetalous and ringent; the tube is almost cylindric, the upper-lip is concave, and divided into two obtuse segments; the lower-lip is trifid, equal, and plane; the stamina are four in number, two of which are shorter than the rest; the germen is quadrifid, and after-

wards

wards becomes four seeds, which ripen in the cup. The flowers of this genus are produced on the stalks in whorled spikes, they are of a purple colour, and the leaves, which are pointed, have an aromatic odour and flavour when bruised.

THYMELÆA, in botany. See DAPHNE.

THYMUS, the thyme plant, in botany, a genus of plants, the flower cup of which is labiated and persistent; the upper-lip is broad, plane, erect, and tridentated, and the under one ends in two bristles which are of an equal length. The corolla is monopetalous and ringent; the tube is the length of the cup; the faux, or chaps, are small; the upper-lip is short, plane, erect, obtuse, and emarginated; the lower-lip is long, patent, broad, trifid, and obtuse, the middle lacinia being broadest; the stamina are four incurved filaments, two being longer than the others, and the antheræ are small; there is no pericarpium, but the cup, whose neck is narrowed, contains four small roundish seeds. This genus includes the acinos of Dillenius, and the serpyllum of Tournefort, or mother of thyme.

There are several sorts of thyme, as the broad-leaved thyme, narrow-leaved thyme, variegated thyme, orange and lemon thyme, so called, &c. they are all easily propagated, by sowing their seeds or parting their roots, which may be done either in the spring or autumn; a dry soil is best for these plants, as their virtues are stronger than if growing in moist wet lands, and likewise they are not so apt to be destroyed in severe winters.

The common thyme has an agreeable aromatic smell, and a warm pungent taste; it therefore not only enters into many culinary compositions, but is sometimes used in medicine: it is said to strengthen the brain, and to attenuate and rarify clammy humours; it helps digestion, and may be of some service in shortness of breath; the distilled spirit is an agreeable, aromatic cordial liquor, and not inferior to any thing of the kind.

THYMUS, in anatomy, a gland, which in infants is very remarkable: it is situated in the upper part of the thorax, immediately under the sternum, and lies upon the pericardium, and on the trunk of the aorta, and of the vena cava. It extends itself from the pericardium, along the trunk of the aorta, to the beginning of the carotids, sometimes so far as to the thyroide-gland; its figure is irregular and uncertain; its colour in infants is a pale red, in adults it is of a dusky hue: it is much larger in infants newly born, than in subjects at any more advanced period. Its length is there no less than three fingers breadth, and its diameter two, its thickness is about half a finger: it gradually decreases from this size, as the child grows up; in adults it is very small, and in old people it entirely disappears. Its substance is glandulous and conglomerate, and it is surrounded by a membrane. It has blood-vessels sometimes from the subclavians, sometimes from the

mammary, and sometimes from the mediastine ones; and in some subjects from the carotids and jugulars. Its lymphatics sometimes run to the thoracic duct, sometimes to the subclavian veins; and they have in general no valves.

The nerves of the thymus are from the par vagum, or from the intercostals. There is sometimes a milky juice found in this gland, in new-born subjects. It has no excretory duct hitherto discovered, and its use is therefore not certainly known: possibly, according to Heister, it serves to secrete lymph, which it discharges into the thoracic duct, for the dilution of the blood and of the chyle, as the glands of the mesentery, and of the pancreas do, in regard to the chyle. On this supposition its use is much greater in the foetus, than at any time after the birth, because the want of respiration in that state may well be supposed to subject the blood to be thicker, and to need more dilution than afterwards; nothing tending to attenuate blood so much as respiration. Bellinger is of opinion, that it prepares a nutritious fluid for the foetus while in the uterus, and conveys it by particular ducts to its mouth; but it is to be observed, that neither Bellinger himself, nor any body since, have ever been able to find out these ducts.

THYROARYTÆNOIDES, in anatomy, a muscle of the larynx, which, arising and terminating in it, serves, together with the arytenoides, to constrict it. These two muscles mutually intersect one another, and straiten the glottis; sometimes there is but one muscle; and sometimes it is different from that described here.

THYROIDE GLAND, in anatomy, is of a very singular figure, resembling that of the new moon. It adheres by its middle part, which is called by authors its isthmus, to the upper ring of the trachea, and its points or horns are turned upwards. It adheres on each part to the larynx and œsophagus.

THYROIDE CARTILAGE, one of the five cartilages that principally compose the larynx.

THYROSTAPHYLINUS, in anatomy, the name of a muscle of the uvula, which, arising from the lateral part of the thyroide cartilage, and ascending towards the uvula, becomes larger, and is inserted in manner of an arch, in the side of the velum palatinum.

THYRSUS, in antiquity, the sceptre which the poets put into the hand of Bacchus, and wherewith they furnished the Menades in their Bacchanalia.

The thyrsus was originally a lance or spear, wrapped up in vine-leaves, wherewith Bacchus is said to have armed himself and his soldiers in the Indian wars, to amuse and deceive the unpractised Indians, and make them expect no hostilities.

TIARELLA, in botany, a genus of plants, whose flower consists of five oblong petals, which are inserted in the cup: the stamina are ten slender filaments, longer than the corolla, and topped with roundish

Fig. 8.

roundish antheræ: the germen is bifid and ends in two styles: the fruit is an oblong, unilocular, and bivalvular capsule, containing a number of ovate shining seeds.

**TIBIA**, in anatomy, is the inner and bigger bone of the leg, called also *os majus*: it is hard and firm, with a cavity in its middle; it is almost triangular; its fore and sharp edge is called the *shin*.

**TIBIALIS**, or **TIBIÆUS**, in anatomy, the name of two muscles of the foot, distinguished by the epithets *anticus* and *posticus*.

The *tibialis anticus*, one of the flexor muscles, has its origin from the superior and extensor surface of the tibia, and is terminated at the internal os cuneiforme, and the interior part of the internal metatarsal bone.

The *tibialis posticus*, or abductor muscle of the foot, has its origin in the upper part of the interosseous ligament, and its termination in the os naviculare. See **FOOT** and **MUSCLE**.

**TIDES**, two periodical motions of the waters of the sea, called the flux and reflux, or the flow and ebb.

The cause of the tides is the attraction of the sun and moon, but chiefly of the latter; the waters of the immense ocean, forgetful, as it were, of their natural quietus, move and roll in tides, obsequious to the strong attractive power of the moon, and weaker influence of the sun.

To illustrate this, let **NESQ** (plate **LXXXVII**. fig. 3.) represent the earth, covered over with water **ABDF**; **NS** the axis of the earth, **EQ** the equator, **TR** the tropic of Cancer, *tr* the tropic of Capricorn, **M** the moon in her orbit, **S** the sun in his. Now, since all bodies are endued with an attracting virtue, the moon will attract all the water in the nearest hemisphere **FAB**, with degrees of force which are inversely as the squares of the distances from all parts; and therefore, with the strongest force where the distance is least, viz. in the point **A**, directly under her: and this attraction being, in this hemisphere, contrary to that of the earth, the water in all the parts from **B** to **F** towards **A**, will have its gravity decreasing, and be highest of all at the part **A**; and, consequently, must there stand higher than at the point **F**, where being more attracted by the earth, it must be heavier and nearer to the center, as is evident by the laws of hydrostatics. See **FLUID**.

Again, in the hemisphere **FDB**, the attraction of the moon conspires with that of the earth; but decreasing as the squares of the distances increase, the joint force of attraction will every where decrease from **F** and **B** towards **D**, the point opposite to the moon; where, again, the waters will be lightest, and therefore stand highest to preserve the equilibrium.

Whence it appears, that by this sum and difference of the moon's and earth's attraction, there will necessarily ensue a protuberance or swelling of the waters, which we call tides of flood, in the two points **A** and **D** directly under the moon. Also in the two points **F** and **B**, as the waters are there most attracted, so they will be heaviest, and consequently rise to the least height from the earth's surface, whence they are called tides of ebb, or the ebbing of the water.

If to the power of the moon we add that of the sun, we shall have the tides considerably augmented at the conjunction in **S**, or opposition in **H**, that is, at the new and full moons, which are called the spring-tides; as those which happen when the sun is at **O** or **P**, are called neap-tides, the waters at **A** and **D** being then lowest, because the attraction of the moon is then counterbalanced by that of the sun.

It is further to be observed, that of the two tides of flood at **A** and **D**, that at **A** is greatest to any place **T** in the northern latitude, when the moon is in the northern signs, and above the horizon; for the point **A** is then nearer the zenith of the place **G**, than the opposite point **D** is to the same place at **R** twelve hours afterwards; and, consequently, the height of the tide **TG** is greater than that of the opposite tide **Rg**. The contrary of this happens, when the moon is in the southern signs.

That there are two tides of flood and two of ebb, succeeding each other alternately at about the interval of six hours, is obvious from the figure: and that they happen later each day near an hour, is owing to their exact correspondence to the motion of the moon, which daily culminates so much later. That they happen not when the moon is in the meridian, but about three hours after, is owing to the force of the moon being then greater than when in the meridian of any place; as the heat of the day is greater at three o'clock than at twelve; and the heat of the summer is greater in August than at the 21st of June. Lastly, that the greatest spring tides happen not at the 21st of March, and 23d of September, but in February and October, is because the sun being nearest the earth in December, his influence is then strongest, and so must quicken the time of the greatest vernal tides; and being weakest in June, the time of the autumnal tides will necessarily be retarded.

The sum of what has been said is this: if **NOPQ** (fig. 4.) be the surface of the earth, **T** its center, **IFKGLHCE** a circle representing the spherical surface of the waters covering the earth, and affected only by the attractive power of the earth: upon placing an attracting body at **S**, the waters will no longer continue their spherical figure, but be immediately drawn into the spheroidal figure **ACBD**, in such manner, as to be depressed at **C**

and D to M and K, and elevated from L and I to A and B; and the elevation A L or B I, is double the depression C M or D K. That if S be the sun, then  $AP - OK = AL + KD = 25$  inches; or  $11\frac{1}{2}$  feet, if S be the moon. That at the points E, F, G, H, (which are called the octants) the water is neither elevated nor depressed. That if any other body be placed at O (as the moon) in the same right-line T S; then by the joint influence of both S and O, the elevation at A and B will be increased, and the depression at C and D likewise. Lastly, if S be in the situation S, or vertical to the point D, it is plain its action to raise the water D will be directly contrary to that of the moon in depressing it there; wherefore the depression will not be so great as before; for the same reason the elevation at A and B will be diminished, being now only as the difference of the two forces, whereas before they were as the sum.

We shall now consider the phenomena of the tides which remain; and first, it is evident, that if P N be the axis of the earth, and Q O the diameter of the equator, then the moon situated at O, over one of the poles, would accumulate the water over each pole, and the spheroid would be so posited as to have its longest axis A B coinciding with the axis of the earth P N. In this position of the spheroid, it is plain, there could be no such thing as a tide in any part of the ocean over all the earth; for every section of the spheroid, parallel to the equator, would be a circle; consequently in any parallel of latitude, the water would be at equal distance from the earth's surface every moment of the diurnal revolution, or natural day.

Suppose the moon were removed from the direction of the earth's axis, and posited at S (fig. 5.) then will the axis of the aqueous spheroid A B be turned towards S, and make an angle with the earth's axis, as A T P or B T N. Then we observe, that since C, D, are the places of lowest water, that parallel I K which passes through the point I on one side the equator, and L M which passes through M on the other, will divide the earth into three zones, in two of which, viz. E N K and L P M, there will be but one tide each day, of the same kind; for instance, in the parallel E F, a person at F will have high water, and at E low water for twelve hours after. Again, in all the zone I K M L, there will be two tides of the same kind each day, as is evident from the figure. These limits, or the arch Q I or O M, is the complement of the moon's declination from the equator.

If the moon at S (fig. 6.) be over the equator, the longer axis of the spheroid A B will now coincide with the plane of the equator Q O, and the shorter axis C D with the axis of the earth N P. Here it is obvious, that in this situation of the spheroid, the waters in the parts A B, with respect to those at C D, will give the greatest difference of

high and low water possible to all parts of the earth; and that there is no place but those two at the poles N, P, but what has two tides of flood, and two of ebb every twenty-four hours. And this difference of the flux and reflux will decrease from the equator to the poles.

It has been already observed, that the greatest elevation of the waters is not when the luminary is in the meridian, but about three hours after, because the motion communicated to the waters during the arrival of the meridian is not immediately destroyed, but remains some time, and receives a farther augmentation from that which is impressed for about three hours after. For the same reason, we observe, the greatest and least tides happen not on the day of the syzygy, or quadrature, but on the third or fourth after; the sum or difference of the forces of the luminaries not being till then at a maximum. See the article SYZYGY.

Let S F E G (fig. 7.) be the orbit of the moon about the earth Q N O P, which as it is not circular but elliptical, the center of the earth, T, will not be always at an equal distance from the moon; but the moon will be sometimes nearest the earth, as when at S, and sometimes farthest off, as at E. The point S is called the perigæum, or perigee; and the point E the apogæum, or apogee. The power of the moon in her perigee is to that in the apogee nearly as  $TE^3$  to  $TS^3$ ; and consequently the greatest tides will be on the day of the perigee, or rather a few days after, for the reasons above-mentioned. Such would the tides regularly be, if the whole earth were covered with deep sea; but by reason of the shoalness of some places, and the narrowness of the streights, by which the tides are, in many places, propagated, there arises a great diversity in the tides, not to be accounted for without an exact knowledge of all the circumstances of the several places where they happen; as of the position of the land, the breadth and depth of channels, &c.

That the tides may have their full motion, the ocean in which they are produced ought to be extended from east to west  $90^\circ$ , or a quarter of a great circle of the earth, at least; because the places where the moon raises most, and most depresses the water, are at that distance from one another. Hence it appears, that it is only in the great oceans that such tides can be produced; and why, in the large Pacific ocean, they exceed those in the Atlantic ocean: hence also it is obvious, why the tides are not so great in the torrid zone, between Africa and America, where the ocean is narrower, as in the temperate zones on either side; and from this also we may understand why the tides are so small in islands, that are very far distant from the shores. It is manifest, that, in the Atlantic ocean, the water cannot rise on one shore but by descending on the other; so that, at the intermediate distant islands, it must continue at about a mean height

betwixt its elevation on the one and on the other shore.

As the tides pass over shoals, and run through freights into bays of the sea, their motion becomes more various, and their height depends on a great many circumstances.

The tide that is produced on the western coast of Europe, corresponds to the theory above described: thus, it is high water on the coast of Spain, Portugal, and the west of Ireland, about the third hour after the moon has passed the meridian: from thence it flows into the adjacent channels, as it finds the easiest passage. One current from it, for example, runs up by the south of England, and another comes in by the north of Scotland: they take a considerable time to move all this way, and it is high-water sooner in the places to which they first come; and it begins to fall at those places, while the two currents are yet going on to others that are farther in their course. As they return, they are not able to raise a tide; because the water runs faster off than it returns, till, by a new tide propagated from the ocean, the return of the current is stopped, and the water begins to rise again.

The tide takes twelve hours to come from the ocean to London-bridge, so that, when it is high-water there, a new tide is already come to its height in the ocean; and, in some intermediate place, it must be low-water at the same time. In channels, therefore, and narrow seas, the progress of the tides may be, in some respects, compared to the motion of the waves of the sea.

Our author also observes, that when the tide runs over shoals, and flows upon flat shores, the water is raised to a greater height than in the open and deep oceans that have steep banks; because the force of its motion cannot be broke, upon these level shores, till the water rises to a greater height.

If a place communicates with two oceans (or two different ways with the same ocean, one of which is a readier and easier passage) two tides may arrive at that place in different times, which, interfering with each other, may produce a great variety of phenomena. An extraordinary instance of this kind is mentioned by our author at Bathsha, a port in the kingdom of Tunquin in the East-Indies, of northern latitude  $20^{\circ} 50'$ . The day in which the moon passes the equator, the water stagnates there without any motion: as the moon removes from the equator, the water begins to rise and fall once a day; and it is high-water at the setting of the moon, and low-water at her rising. This daily tide increases for about seven or eight days, and then decreases for as many days by the same degrees, till this motion ceases when the moon has returned to the equator. When she has passed the equator, and declines towards the south pole, the water rises and falls again, as before; but it is high-water now at

the rising, and low-water at the setting, of the moon.

This theory of the tides has been extended so far, as to estimate the tides, or elevations of the waters of the moon, produced by the attraction of the earth: thus, let us suppose the quantity of matter ( $Q$ ) in the earth to be to that in the moon ( $q$ ) as 40 to 1; that is,  $Q:q::40:1$ ; and let us first suppose the earth and moon of equal bulk, and represented by AIK (fig. 8.) and BDE, and the force ( $F$ ) of the earth, at the surface of the moon B, will be to the force ( $f$ ) of the moon, at the surface of the earth A, directly as the masses of matter in each (because of the equal distances TB and LA) that is,  $F:f::Q:q::40:1$ . Again, let LB be to LC as the diameter of the earth to that of the moon, which is as 365 to 100, then will the force at B be to the force at C, as LB to LC, which let be as  $F$  to  $f$ , then  $F:f::365:100$ , whence  $F=\frac{365f}{100}$ ; and above we have  $F=40f$ , therefore  $4000f=365f$ ; and so  $f:f::365:4000::1:11$ , nearly; that is, the power of the earth to raise the water at the moon C, is to that of the moon at the earth A, as 11 to 1, very nearly.

If the moon can raise the water here 10 feet, the earth can raise the water there to the height of 100 feet; but because the moon always turns about her axis in the same time as she revolves about the earth, the waters (if any there be) will be raised on this and the opposite side, and always continue over the same part of the moon's surface, so that there can be no different heights of water there, and consequently no tides, except what small ones may happen on account of the sun's attraction, and her various inequalities of motion, and distance from the earth.

The air, which is 860 times lighter than water, must yield in proportion more easily to the attracting force of the sun and moon; and therefore the tides will, in this profound and vast aerial ocean, be very considerable and importing. See the articles ATMOSPHERE, HEAT, WIND, &c.

TIERCE, or TEIRCE, a measure of liquid things, as wine, oil, &c. containing the third part of a pipe, or forty-two gallons. See the article MEASURE.

TIGE, in architecture, a French term for the shaft or fust of a column, comprehended between the astragal and the capital. See the articles COLUMN and SHAFT.

TIGER, or TYGER, *Tigris*, in zoology, an animal belonging to the felis-kind, with an elongated tail, and variegated spots.

TILIA, the lime, or linden-tree, in botany, a genus whose flower consists of five oblong blunt petals, crenated at the points; the filaments are awl-shaped, numerous, the length of the corolla, and topped with single antheræ; the germen is roundish

roundish, the style slender and the length of the stamina, and the stigma is pentagonally obtuse; the fruit is a globose coriaceous capsule, having five cells, and opens at the base with five valves, each cell containing a roundish seed.

The common lime-tree has a deep spreading root, that sends forth a very large trunk, which produces so many branches as to render it very proper for shady walks; it is covered with a smooth bark, which is yellowish or whitish within, and is so tough and flexible, that, in some places, where better materials are scarce, they make cords or cables therewith: the leaves are broad, roundish, and terminate in a point; their edges are dentated, and their upper surface is generally covered with a honey dew, and the flowers grow in bunches.

This tree is of a very long duration, and often of a large magnitude; it naturally grows in a pyramidal form, and has a beautiful appearance; tho' of late years, it has not been held so much in esteem as formerly, because it is late in the spring before the leaves come out, and is the first which sheds them, particularly when planted in a dry soil; the leaves frequently decay in July, and are continually falling off, making a litter all the remaining part of the summer.

Besides this sort, there are the small-leaved lime-tree, the red-twigg'd lime-tree, the Carolina lime-tree, and the American black lime-tree; the three first sorts are common in England, and are cultivated in most nurseries; but the Carolina and American are not yet very common.

They are all easily propagated by layers, which in one year will take good root, and then may be taken off and planted in the nursery, at about four feet distance row from row, and two feet asunder in the rows. The time to lay them is in September, and autumn is the best season for planting, though in moist lands the spring is as well.

The timber of the lime is used by carvers, it being a soft light wood; also by architects, for framing the models of their buildings: it is likewise used by turners for making light bowls, dishes, &c.

The flowers of the lime-tree are said to be good in all disorders of the head, and may be drank in the manner of tea; and some make a conserve of them for the same purpose: they are also reckoned good in the stone and gravel, and to dissolve coagulated blood: the berries are astringent, and good against all hæmorrhages and loosenesses; the dose in powder is a dram.

**TILLÆA**, in botany, a genus of plants, whose flower consists of four ovate, acute, and plane petals, with four filaments, shorter than the corolla, and topped with small antheræ: the fruit consists of four oblong, acuminate, reflexed capsules, each containing two ovate seeds.

**TILLANDSIA**, in botany, a genus of plants, whose flower is monopetalous and tubulated; the

tube is long and ventricose, and the limb is trifid; obtuse, erect, and small: the stamina are six filaments, terminated with acute antheræ, which lay down on the neck of the corolla: the fruit is a long acuminate capsule, obtusely trigonal, and containing one cell, which incloses several seeds affixed to a long capillary down.

This genus includes the *caraguata* and *renealmia* of Plumier.

**TILLER**, in husbandry, denotes a young tree, left to grow till it be felleable for timber.

**TILLER of a Ship**, a strong piece of wood fastened in the head of the rudder, and in small ships and boats called the helm.

**TILLAGE**, in husbandry, is the opening, breaking, and dividing the ground with the spade, the plough, the hoe, or other like instrument.

**TIMBER**, includes all kinds of felled and seasoned woods.

**TIME**, *Tempus*, a succession of phaenomena in the universe; or a mode of duration, marked by certain periods or measures, chiefly by the motion and revolution of the sun.

The idea of time, in the general, Mr. Locke observes, we acquire by considering any part of the infinite duration as set out by periodical measures: the idea of any particular time, or length of duration, as a day, an hour, &c. we acquire first, by observing certain appearances at regular, and, seemingly, at equidistant periods.

Now, by being able to repeat those lengths or measures of time, as often as we will, we can imagine duration, where nothing really endures or exists; and thus we imagine to-morrow, next year, &c.

Some of the latter school-philosophers define time to be the duration of a thing, whose existence is neither without beginning nor end: by which time is distinguished from eternity.

Time is distinguished into absolute and relative. Absolute time, is time considered in itself, and without any relation to bodies, or their motions. This flows equally, i. e. never proceeds faster or slower, but glides on in a constant, equable tenor. Relative time, is the sensible measure of any duration by means of motion. For since that equable flux of time does not affect our senses, nor is any way immediately cognizable thereby, there is a necessity for calling in the help of some nearly equable motion to a sensible measure, whereby we may determine its quantity, by the correspondency of the parts of this with those of that.

Hence, as we judge those times to be equal which pass, while a moving body, proceeding with an equable velocity, passes over equal spaces; so we judge those times to be equal which flow while the sun, moon, and other lumimaries, perform their revolutions, which, to our senses, are equal.

But since the flux of time cannot be accelerated,

nor retarded, (whereas all bodies move sometimes faster and sometimes slower, and there is, perhaps, no perfectly-equable motion in all nature) it appears hence to follow, that absolute time should be something truly and really distinct from motion. For let us suppose the heavens and stars to have remained without motion from the very creation, does it hence follow, that the course of time would have been at a stand? Or, rather, would not the duration of that quiescent state have been equal to the very time now elapsed?

*Astronomical TIME*, is that taken purely from the motion of the heavenly bodies without any other regard.

*Civil TIME*, is the former time accommodated to civil uses, and formed and distinguished into years, months, days, &c.

*TIME*, in music, is an affection of sound, whereby we denominate it long or short, with regard to its continuance in the same degree of time.

Common, or duple time, is of two species. 1. When every bar or measure is equal to a semi-breve, or its value, in any combination of notes of a lesser quantity. 2. When every bar is equal to a minim, or its value, in lesser notes.

*TIN*, *Stannum*, *u*, a well-known whitish metal, softer than silver, yet much harder than lead.

Tin is the lightest of all the metals; it is remarkable for a quality that no other of them has, which is, that when bent it makes a crackling noise. It is harder than lead, but less so than any other of the metals: it is malleable in a very remarkable degree, though less so than lead: it may easily be drawn into a course wire, but if this be attempted to be brought to any degree of fineness, it snaps and breaks under the workman's hands.

Tin is less susceptible of rust than most of the other metals: it is very little elastic, and scarce at all sonorous. It melts with a much smaller degree of fire than any other metal, a heat but a little greater than boiling-water being sufficient to fuse it. It melts before it grows red hot, like lead: and a degree of heat so much less even than that requisite to the running of lead, is necessary to the fusing of this metal, that it may be easily separated from the other by aliquation; and if the fire be kept under a mixed mass of the two, so low as to be just hot enough to melt the lead, the tin will all run off from it.

Tin amalgamates very readily with mercury, and may be mixed in fusion with most other metals, and as readily separated from them again by the before-mentioned process of eliquation. It is the least simple of all the metals, being brought, by a very small degree of fire, to emit sulphureous fumes: these are plainly the absolute sulphur of the metal. They do injury to the people employed to work upon it, rendering them pale, and often absolutely destroy them. The consequence of the emitting these fumes so a-

bundantly is, that tin, of all metals, loses most of its weight, and calcines most easily in the fire. Exposed to the focus of a great burning-glass, it immediately melts, and sends off a large quantity of thick white fume; the remaining matter is then a fine cry stalline or glossy matter, in form of needles; these, if held ever so long in the same heat, undergo no farther change, never running into a mass of glass, as the remains of most of the metals do under the same circumstances; but, like the glasses of the other metals, if exposed again to the same heat, laid on a piece of charcoal, they immediately run into tin again; and the same thing happens if it be continued on the tile or coppel it was first placed on in the focus, and some fat matter, as tallow, or the like, to be added to it.

Filings of tin, thrown into the flame of a candle, take fire, and render the flame blue, emitting a visible fume, and a smell of garlic: melted in a crucible, with a mixture of nitre, it deflagrates. Its constituent matters, therefore, seem to be a crystalline earth, which melts with great difficulty, and an inflammable sulphur; in which, from its smell while calcining, and from its poisonous quality, it is probable there may be something of arsenic mixed.

For the specific gravity of pure tin, see the article *GRAVITY*.

Tin so far endures the force of lead and antimony in the refiner's test, that it is hardly to be separated from them, unless by the addition of copper: it adheres to the rest of the metals with greater ease than any other, and hence it is in continual use in covering plates of iron, and lining copper, and other metals, to prevent their rusting, and to save the liquids put into them from taking up any bad qualities from those metals, as it is much more difficultly solved by common menstrua than either of them.

Tin, in many things, greatly approaches to the nature of silver. It very readily melts with silver, gold, or copper; when the mixture is made with equal, or even a less quantity, it renders them extremely brittle: but it is very singular, that if it be mixed in a much larger quantity, they still continue pliant and flexible. Ten parts of tin and one of copper, make a mass more rigid indeed than tin, yet malleable and ductile. Silver, of all metals, suffers most by an admixture of tin, a very small quantity of it serving to make that metal as brittle as glass; and what is worse, being very difficultly separated from it again.

The addition of about one-tenth part of copper to tin, makes it fit for the common uses of life, in vessels of various kinds, as it becomes, by the mixture, more durable; a little zink, added to this mixture, gives the metal a yellow colour; and, as it is mixed in greater or less quantity, makes it fit for casting of cannon and for bells.

Iron readily mixes with tin, in fusion, if the fire be

be brisk, and the iron be heated white-hot before the tin be added. Twice the quantity of this metal, added to iron so heated, readily runs with it into an odd substance, which is very white and brittle, and readily answers to the magnet. This has been used by some, as a pretence of its not being iron, and that the load-stone would attract another metal beside that: but the fallacy is easily discovered by any one that understands any thing of the metallurgic analysis.

Lead bears a considerable admixture of tin, without being affected as gold and silver are, which are both rendered brittle by it; at least, its effects on this metal are in a much smaller degree. The very vapour of tin has the same effect with the metal itself on silver, gold, and copper, rendering them brittle. Many a metallurgist has been long plagued by these vapours by a piece of tin being accidentally among his charcoal; the consequence of which has been, that, till it was burned wholly away, these metals have been rendered as brittle as glass under the hammer, by only being fused over these coals.

It is owing to this property of tin, in making the metals it is mixed with brittle, that it renders them sonorous. Mr. Boyle has expressed a wonder that tin, which is itself not much sonorous, should on mixture with copper render it more so; but if we consider, that the same sort of disposition of parts which renders metals rigid and brittle, renders them sonorous, the mystery is explained.

The proper solvent of tin, in its true malleable state, is aqua regia. It will not well dissolve in any of the other menstrua of the stronger kinds, nor indeed very readily in this. We are not, however, to wonder at this difficulty of solution in tin, since we find it contains much more sulphur than any other metal, and sulphur is not one of those substances that are to be dissolved by acids. That this is a fact, we find by putting calcined tin, instead of common malleable tin, into the menstruum, for in this case even vinegar will dissolve it. While tin is in its malleable state, the weakest acids dissolve it best. Verjuice, and, it is said, even four apples, boiled in tin vessels, acquire a taste of that metal, though the strongest acids (aqua-regia excepted) boiled in the same vessels, acquire no flavour from it at all.

Many of the chemical writers have been of opinion, that, if the sulphur could be thoroughly purged from tin, it would be no longer tin, but silver; it is certain that the two metals have many things in common. If dissolved in aqua-regia, tin is bitter, as well as silver, in solution with the nitrous acid; but the crystals which are produced from a solution of it in vinegar, after it has been calcined for forty-eight hours together, which is a necessary step towards such a solution (and which one would think should bring it nearer to silver than before, if

the dissipating its sulphur were the way to do it) differ wholly from those of silver. We have indeed accounts, in many authors, of tin being made to yield a large quantity of silver by peculiar processes; but that careful experimenter, Mr. Boyle, tells us, that all tin is not to be expected to yield those advantages in the same manner, for that himself had separated pure crystals of silver from one parcel of tin by a peculiar menstruum, but that another parcel of the same metal would not answer in the same manner.

Though tin and lead readily unite in fusion over a gentle fire, if the heat be afterwards raised to a violent degree, there is a visible motion excited in the mixture; and the consequence is, that both are reduced to a calx, and the lead becomes extremely difficult afterwards to vitrify.

The effect that zink has upon a mixture of tin and copper (the copper being in a larger proportion than has been usually given in such mixtures) is little known, and seems to be a secret that the people who are possessed of it intend to make use of to themselves.

The virtues of tin, as a medicine given internally, have been celebrated by many of the ancient writers, but it has less credit at present. We have been told, that in diseases of the lungs, and in disorders of the head and uterus, there is scarce any thing equal to it; and that in convulsions, epilepsies, and the madness arising from the bite of a mad dog, it was a certain remedy. These last are the only cases in which it has any credit at present, and that is rather among the vulgar than among physicians.

To these preparations used in medicine, we may add one well known as a cosmetic: it is a magistery of tin prepared in the manner of that of bismuth, by first mixing six ounces of spirit of nitre with one ounce of spirit of sea-salt, and then putting tin into this liquor, or aqua-regia, till it is capable of holding no more: lastly, pour the solution into six or eight quarts of spring-water, and the tin will be precipitated in form of a white powder, which should be washed several times, and then dried for the use of ladies in pomatums, to render the skin white and soft.

**TINCTURE**, *Tinctura*, in pharmacy and chemistry, a separation of the finer and more volatile parts of a mixed body, made by means of a proper menstruum dissolving and retaining the same.

Rectified spirit of wine dissolves the volatile oils and resins of vegetables, whilst water acts more immediately on their mucilaginous and saline matter. Hence, in whatever proportion the soluble parts of any vegetable are blended together, a spirit may be so adjusted thereto by art, as entirely to dissolve the whole, and consequently to extract all the virtues of the subject, without any of the useless or woody parts. Fixed alkaline salts deepen the colour

four of spirituous tinctures, but add nothing to the dissolving power of the menstruum; nor is the addition of these salts useless only, but likewise prejudicial, as they injure the flavour of aromatics, and superadd a quality sometimes contrary to the intention of the medicine. Volatile alkaline salts, in many cases, promote the action of the spirit; but acids, almost universally, weaken it. See **ALKALI** and **ACID**.

As to the method of extracting tinctures, the following general rules may be of use in this respect.

1. The vegetable substances ought to be moderately and newly dried, unless they are expressly ordered otherwise; they should likewise be cut and bruised before the menstruum is poured on them. 2. If the digestion is performed in balneo, the whole success depends upon a proper management of the fire: it ought to be all along gentle, unless the hard texture of the subject should require it to be augmented; in which case the heat may be so increased as to make the menstruum boil a little towards the end of the process. 3. Very large circulatory vessels ought to be employed for this purpose, which should be heated before they are luted together. A commodious circulatory may be composed of two long-necked matrasses or bolt-heads, the mouth of one of which is to be inserted into that of the other, and the juncture secured by a piece of wet bladder. The use of heating the vessels is, to expel a part of the air; which otherwise, rarifying in the process, would endanger bursting them, or blowing off the uppermost matrass. 4. The vessel is to be frequently shaken during the digestion. 5. All tinctures should be suffered to settle before they are committed either to the filter or strainer. 6. In the tinctures, and distilled spirits likewise, designed for internal use, no other spirit, drawn from malt, melasses, or other fermented matter, is to be used, than that expressly described.

Of tinctures there are various sorts, and for various uses; cephalic tinctures, antiscorbutic tinctures, stomachic tinctures, anticolic tinctures, and invigorating tinctures; there are tinctures drawn from roses, from cinnamon, and an infinite number of other substances, which it would be too tedious to mention.

**TINCTURE**, in heraldry, the hue or colour of any thing in coat armour, under which denomination may also be included the two metals, *or* and *argent*, because they are often represented by yellow and white.

**TIN-GLASS**, a name given by some to a mineral matter more commonly called bismuth. See the article **BISMUTH**.

**TINGING of Marble**. The art of doing this has, in several peoples hands, been a very lucrative secret, though there is scarce any thing in it that has not at one time or other been published. Kircher has the honour of being one of the first, who pub-

lished any thing practicable about it. This author meeting with stones in some cabinets, supposed to be natural, but having figures too nice and particular, to be supposed of nature's making, and these not only on the surface, but sunk through the whole body of the stones, was at the pains of finding out the artist, who did the business; and on his refusing to part with the secret on any terms, this author, with Albert Gunter, a Saxon, endeavoured to find it out; in which they succeeded at length very well. The method is this: Take aqua fortis and aqua regia, of each two ounces; sal armoniac, one ounce; spirit of wine, two drams; about twenty-six grains of gold, and two drams of pure silver; let the silver be calcined and put into a vial, and pour upon it the aqua-fortis; let this stand some time, then evaporate it, and the remainder will first appear of a blue, and afterwards of a black colour. Then put the gold into another vial, pour the aqua regia upon it, and when it is dissolved, evaporate it as the former. Then put the spirit of wine upon the sal armoniac, and let it be evaporated in the same manner. All the remainders, and many others made in the same manner from other materials, dissolved in their proper acid menstrua, are to be kept separate, and used with a pencil on the marble. These will penetrate without the least assistance of heat; and the figure being traced with a pencil, the several parts are to be touched over with the proper colours, and this renewed daily till the colours have penetrated to the desired depth into the stone. After this, the mass may be cut into thin plates, and every one of them will have the figure exactly represented on both surfaces, the colours never spreading. The nicest method of applying these, or the other tinging substances, to marble, that is to be wrought into any ornamental works, and where the back is not exposed to view, is to apply the colours behind, and renew them so often till the figure is sufficiently seen through the surface on the front, though it does not quite extend to it. This is the method that, of all others, brings the stone to a nearer resemblance of natural veins of this kind.

**TINNING**, the covering or lining any thing with melted tin, or with tin reduced to a very fine leaf. Looking-glasses are foliated, or tinned, with thin plates of beaten tin, the whole bigness of the glass, applied or fastened thereto by means of quicksilver.

The plumbers, on some occasions, tin or whiten their sheets of lead, in order to which they have a tinning-furnace, filled with live coal, at the sides whereof two men are placed, who hold up the sheets over the fire to heat; and the tin leaves being laid over them as fast as the sheets grow hot, and the tin melts, they spread it, and make it take by rubbing it with tow and rosin.

**TINNATUS AURIUM**, a noise or buzzing in the ear, when it receives sounds which do not exist,

or at least which are not produced by the motion of the external air; and the ear being filled with a certain species of sound, cannot admit other sounds, unless they are very violent. The tinnitus is of two kinds, the one proceeding from a distemperature of the organ of hearing, the other from a disorder of the brain.

The cure, according to Heister, is to be performed by temperate diaphoretic powders, and resolving essences, commonly called anticatarrhals; as of amber, the woods, rosemary, together with diaphoretics and alexipharmics, taken often in a day, with tea of betony, with rosemary flowers, sage, or lavender, or sassafras. In the morning, and at noon, the essences are to be taken, and at night the powders. Essence of amber may be applied outwardly, either alone or with a few drops of oil of amber, or one or two drops of oil of camomile put into the ear with cotton, morning and evening; or a grain or two of amber and musk, or castor, in cotton, either alone or with Peruvian balsam; or carminative oils, such as anise, fennel, carraways, or camomile; not neglecting pediluvia, and frequent rubbing of the feet and head. Many have also been cured by the vapour of a decoction of lavender flowers, or rosemary, made with wine, being conveyed to the ear with a funnel. If the disease is obstinate and inveterate, the patient must bleed in the foot, together with scarifications, and frequent purges, for the sake of revulsion. Etmüller says, this noise, proceeding from burning fevers, will go away of itself; but if it proceeds from chronic disorders, it is difficult of cure. However, he recommends vapours of southernwood, wormwood, origanum, eyebright, balm, &c. as also of amber, or gum ammoniac; likewise oil of peach kernels, and spirit of urine, put into the ear with cotton.

The following formula is greatly praised. White hellebore and castor, take of each two drachms; of costmary, one drachm and a half; of rue, two drachms; euphorbium, half a drachm; of bitter almonds, two drachms and a half: let them be boiled in oil of rue, and poured warm into the ear. Shaw recommends half an ounce of oil of bitter almonds, with two drachms of oil of castor, externally applied.

**TINUS**, in botany, a genus of plants, whose flower corolla is monopetalous, quinquefid, and obtuse, with an ovate, concave, pitcher-shaped nectarium, perforated at the mouth, and placed in the center of the receptacle; the stamina consists of nine short filaments, topped with heart-shaped antheræ: the fruit is a roundish, trilocular berry, containing three oblong seeds.

This genus comprehends the volkameria.

Tinus is also a name by which some call the Laurustinus. See the articles LAURUSTINUS and VIBURNUM.

**TIPSTAFF**, an officer who attends the judges with a kind of staff tipped with silver, and takes into his charge all prisoners who are committed or turned over at a judge's chambers.

**TIRE**, or **TEER of Guns**, in the sea-language, is a row of cannon placed along a ship's side, either above, upon deck, or below, distinguished by the epithets of upper and lower tires.

**TITANS**, in the heathen mythology, the offspring of Titan, the elder brother of Saturn, upon whom, and his son Jupiter, they made war, in order to recover the sovereignty of which Titan had been deprived. The poets represent them as a race of giants, sprung from the earth, and invading heaven; and tell us, that Jupiter overcame them with thunder, and drove them down to the very bottom of hell.

**TITHES**, *Decimæ*, in law, denote the tenth part of the increase that annually arises from the profits of lands, and the industry of the parishioners, which is payable for the maintenance of the parson of the parish.

**TITHING**, in old law-books, the same with decennary. See DECENNARY.

**TITHYMALUS**, or **TITHYMALOIDES**, spurge, in botany, a genus of plants, whose flower is monopetalous, and contains ten filaments, inserted in the receptacle, and topped with globular antheræ; the germen is roundish, three-cornered, and pedicellated, supporting three bifid styles, crowned with oblong stigmata; the fruit is a roundish capsule, containing three cells, each inclosing an oval seed. This genus is included by Linnæus among the euphorbias.

All the kinds of spurge are full of a milky caustic juice, which is dangerous to take inwardly; it is by some outwardly applied to take off warts and hairs, but it should be used very cautiously.

**TITLE**, *Titulus*, an appellation of dignity, or quality, given to princes, and other persons of distinction.

**TITLE**, in law, denotes any right which a person has to the possession of a thing; or an authentic instrument, whereby he can prove his right.

**TITMOUSE**, *Parus*, in ornithology, a genus of birds, of the order of the passeræ, the beak of which is of a subulated form, and the point of the tongue truncated.

**TITUBATION**, or **TREPIDATION**, a kind of libration, or shaking, which the ancient astronomers attributed to the crystalline heavens, in order to account for certain irregularities which they observed in the motions of the planets.

**TITULAR**, denotes a person invested with a title, in virtue of which he holds an office or benefice, whether he perform the functions thereof or not.

**TOAD**, *Rubeta*, in zoology, belongs to the same

same genus with the common frog. See the article FROG.

The toad is larger than the frog, with a thick body, a broad back, and the belly swelled and inflated: its skin is considerably thick, and full of tubercles, of a dusky and blackish colour on the back, and spotted on the belly: it is naturally a loathsome and disagreeable object.

TOBACCO, *Nicotiana*, in botany, a genus of plants, whose flower is monopetalous and funnel-shaped; the tube is longer than the cup; and the limb, which spreads open, is divided into five acute-pointed segments; the stamina consists of five subulated filaments, topped with oblong antheræ; the fruit is an oval capsule, with a furrow on both sides, opening at the top in two cells, which contain a great many rough kidney-shaped seeds.

There are several species of tobacco; the flowers of some are less acute-pointed than others; they are all natives of America; and brought originally from thence, and at first were in great esteem for their medicinal qualities.

It takes its English name of tobacco from the island of Tobago in the West-Indies, from whence it was first brought by James Nicotius, a French gentleman, in the year 1560.

The description of tobacco seems to be not necessary in this work, because commerce, and its continual use, makes us sufficiently acquainted with it. What is called the Oroonoko tobacco is raised here for the embellishment of the flower-garden; it is propagated by sowing its seeds on a slight hot-bed in the spring, and the plants afterwards removed to where they are intended to remain.

In America, where such large quantities are raised, they transplant them into a rich soil well prepared, taking care as the plants advance in growth to keep them clear of weeds, and to pull off the lowest leaves, leaving ten or fifteen of the finest to receive all the nourishment; when these leaves are ripe, which is known by their breaking when bent, the stalks are then cut, and left to dry two or three hours in the sun, after which they are tied together two and two, and hung on ropes under a shade to be dried in the air, which being sufficiently done, the leaves are pulled from the stalks, and made up into little bundles; which being steeped in sea-water, or, for want thereof, in common water, are twisted in the manner of ropes, and the twists formed into rolls by winding them with a kind of mill around a stick; in which condition it is often imported into Europe, where it is cut by the tobaccoists for smoking, formed into snuff, and the like.

The taste and smell of tobacco is well known, as likewise its effect upon the whole constitution at first use, when smoked or chewed. If it be infused and the liquor drank, it produces sickness, vomiting, and afterwards dosing stupidity; therefore, although it has been used as an emetic among

ignorant people, common prudence will not justify the practice; experience manifests the narcotic properties of tobacco, whether it be only smoked according to the custom of many, or chewed, as some take it, or administered in snuff, it has always the same effect; but upon long practice, like many other things of this kind, it grows less perceivable in such qualities, and with some seems to have no influence at all; but it is somewhat surprising to think what a voluntary punishment people lay on themselves to learn a bad habit, merely because they would follow an unnatural custom, which smoking, chewing, and snuffing tobacco certainly is.

As a ripener or drawer, its heat and penetration gives a disposition to the inclosed humours to ripen; it also quiets and soothes the parts with its narcotic qualities, whereby the irritation is prevented; upon this account it is frequently of great service where there are sharp pains attended with a tumour, and particularly in those of the gout and rheumatism; the leaf bound upon the part is the best way of applying it, especially if it be rubbed over first with a little oil.

But notwithstanding what has been said against the custom of smoking, &c. the use of tobacco may be commended in the time of the plague, and other infectious diseases.

TOD of Wool, a quantity containing twenty-eight pounds; or two stone.

TOES, called by anatomists *digiti pedis*, are the extreme divisions of the feet, answering to the fingers of the hands.

The bones of the toes of both feet are twenty-six in number, sometimes twenty-eight; being much slenderer, except that of the great toe, than those of the fingers: they have also a much less free motion than those of the fingers: the great toe has only two bones, and the rest three; except the little toe in very old people, in whom the two phalanges of the little toe grow together so as to form only one bone; whence we find, in this case, fewer bones in each foot than thirteen.

In case of adhesions of the toes of infants, they should be separated either by cutting out the intermediate skin with a pair of scissars, or barely by dividing them with the same instrument: and when this is done, in order to prevent their cohering again, they should be wrapped up in a spiral bandage, dipped in lime-water and spirit of wine.

TOFT, in law-books, denotes a parcel of land, or a place where a messuage has formerly stood.

TOGA, in Roman antiquity, a wide woollen gown, or mantle; which seems to have been of a semi-circular form, without sleeves; differing both in richness and largeness, according to the circumstances of the wearer, and used only upon occasion of appearing in public.

TOILS, snares or nets used by hunters for catching wild beasts, as deer, &c.

TOILET,

**TOILET**, a fine cloth of linen, silk, or tapestry, spread over the table in a bed-chamber or dressing-room, to undress and dress upon.

**TOISE**, a French measure containing six of their feet, or a fathom.

**TOLERATION**, in matters of religion, is either civil or ecclesiastical. Civil toleration, is an impunity and safety granted by the state to every sect that does not maintain doctrines inconsistent with the public peace: and ecclesiastical toleration, is the allowance which the church grants to its members to differ in certain opinions, not reputed fundamentals.

**TOLL**, in law, a tax or custom paid for passage, or for the liberty of selling goods in a market or fair. Hence, toll booth is a place in a town, where goods are weighed, in order to ascertain the duties thereon.

**TOLUIFERA**, in botany, a large tree which grows naturally in the Spanish West-Indies; the bark is very thick, rough, and of a brown colour; the branches spread out wide on every side, and are furnished with winged leaves, composed of several oblong oval folioles placed alternately, and terminated with an odd one; these are smooth, of a light-green colour, and sit close to the footstalk. The flowers are produced in small bunches at the wings of the branches, each standing upon a slender footstalk. The flower consists of five petals of a yellow colour, inserted in the receptacle, four of which are narrow and equal, and a little longer than the cup, the fifth is much larger, and almost heart-shaped, and has an ungue the length of the cup; the stamina are ten short filaments, topped with oblong erect antheræ; the fruit is roundish, the size of a large pea, divided into four cells, each containing an oblong oval seed.

This tree produces the balsam of Tolu. See the article **BALSAM**.

**TOMAN**, or **TOUMAN**, a kind of imaginary money used among the Persians in the keeping of their books, and to facilitate the reduction of money in the payment of considerable sums. See the article **MONEY**.

**TOMB**, includes both the grave or sepulchre wherein a defunct is interred, and the monument erected to preserve his memory.

**TOME**, in matters of literature, denotes a bound book, or writing that just makes a volume.

**TOMENTUM**, among botanists, the downy matter which grows on the leaves of some plants.

**-tone**, or **TUNE**, in music, a property of sound, whereby it comes under the relation of grave and acute; or it is the degree of elevation any sound has from the degree of swiftness of the vibrations of the parts of sonorous bodies.

**TONGUE**, *Lingua*, in anatomy, the primary organ of taste and speech; the figure of which approaches, in some degree, to pyramidal; its ante-

rior part being called apex, and its posterior part the base or root. The upper side is not quite flat, but a little convex, and divided into two lateral halves, by a shallow depressed line called *linea lingue mediana*. The edges are thinner than the other parts, and a little rounded as well as the point. The lower side reaches only from the middle of the length of the tongue to the point.

The tongue is principally composed of very soft fleshy fibres, intermixed with a peculiar medullary substance, and disposed in various manners. Many of these fibres are confined to the tongue without going any farther; the rest form separate muscles which go out from it in different ways, and are inserted in other parts: all the upper side of the tongue is covered by a thick membrane of a papillary texture, upon which lies another very fine membrane like a kind of epidermis, which is likewise continued over the lowest side, but without papillæ.

Three sorts of papillæ may be distinguished in the upper side of the tongue, *capitata*, *semi-lenticularis*, and *villosa*. Those of the first kind are the largest, resembling little mushrooms with short stems, or buttons without a neck: they lie on the basis of the tongue, in small superficial fossulae. They resemble small conglomerate glands, seated on a very narrow basis, and each of them has sometimes a small depression in the middle of their upper convex side: they occupy the whole surface of the basis of the tongue, and are situated near each other, in such a manner as that the most anterior form an angle; they are glandular papillæ, or small salival or mucilaginous glands, of the same kind with those that are to be described hereafter.

We often observe, about the middle of this part of the tongue, a particular hole of different depths: the inner surface of which is entirely glandular, and filled with small papillæ like those of the first kind. It is called *foramen cæcum Morgagnii*, as being first described by that author; since that time Vaterus has discovered a kind of salival ducts belonging to it; and Heister found two of these ducts very distinctly, the orifices of which were in the bottom of the *foramen cæcum*, near each other. He observed the ducts to run backward, divaricating a little from each other; and that one of them terminated in a small oblong vesicle, situated on the side of the small cornu of the *os hyoides*.

The papillæ of the second kind, or *semilenticulares*, are small orbicular eminences, only a little convex, their circular edge not being separate from the surface of the tongue. When we examine them in a sound tongue with a good microscope, we find their convex sides full of small holes or pores, like the end of a thimble.

They lie chiefly in the middle and anterior portions of the tongue, and are sometimes most visible on the edges, where they appear to be very smooth and polished, even to the naked eye, and sometimes

in living subjects. They soon lose their consistence after death, so that, by rubbing them several times, they may be drawn out in form of small soft pyramids, inclined to one side. The papillæ of the third kind, or villosæ, are the smallest and most numerous. They fill the whole surface of the upper side of the tongue, and even the interstices between the other papillæ. They would be more properly named papillæ conicæ, than villosæ, from the figure which they appear to have, when examined through a microscope. They are naturally softish, but become extremely flaccid after death; so that by handling them they may be made short and thick, whereas they are naturally long and small.

The fleshy fibres of which the tongue is composed, and which go no further than the tongue, may be termed *musculi linguæ interiores*, or the intrinsic muscles; and they are the same with what Spigelius named *musculi linguales*. The fibres these muscles consist of are of three general kinds, longitudinal, transverse, and vertical; and each of these situations admits of different degrees of obliquity. The longitudinal fibres point to the basis and apex of the tongue, and seem partly to be expansions of the *musculi styloglossi*, *hyo-glossi*, and *genio-glossi*. The vertical fibres seem likewise to be in part produced by the same *genio-glossi*, and the transverse by the *mylo-glossi*.

Besides these mixed productions, there is a distinct plane of longitudinal fibres, which run near the surface of the upper side of the tongue, and a distinct transverse plane under them. All these fibres are partly interwoven, one portion of them terminating at the two edges of the tongue, and the other at the basis and point, without going to any other part; and they lie immediately above those which belong to the *genio-glossi*. To discover all these different fibres, and their different degrees of direction, we need only cut the tongue longitudinally, after it has been boiled, or long macerated in strong vinegar. The extrinsic muscles, or *musculi exteriores*, are those which by one extremity make a part of the body of the tongue, and are fixed by the other in some part without the tongue. Of these we reckon four pair, *mylo-glossi*, *stylo-glossi*, *hyo-glossi*, and *genio-glossi*.

**TONGUE-TIED**, the popular name for a distemper of the tongue in children, when it is tied down too close to the bottom of the mouth, by a ligament connected all along its middle, and called its *frænulum*, which requires to be divided, to give the tongue its proper motion.

This is sometimes the case in adults, but oftener in children, who cannot then exert their tongues to suck. This is, however, by no means so common as the women usually imagine; not so much as one child in a thousand being afflicted with it; nor is the operation in cutting it of little consequence, since

often bad accidents follow it, and sometimes the loss of the child's life.

When the infant can put its tongue out of its mouth, the *frænulum* wants no incision; but when the tongue cannot be extended beyond the teeth, the operation is necessary. To perform this, the end of the tongue should be covered with a linen rag, and held with the fingers to prevent its slipping, and the ligament of the tongue running between the ranular veins and internal salival ducts, is to be divided by a pair of obtuse-pointed scissors, till it give room enough for sucking or speaking: but in doing this, great care must be taken not to wound the salival ducts, or the proper veins and arteries of the tongue; for children have been known to perish upon the spot, from the cutting the ranular veins in this operation. Midwives often tear this ligament with their fingers, as soon as the child is born; but this is a dangerous and bad practice.

**TONIC**, *τονικος*, in medicine, is applied to a certain motion of the muscles wherein the fibres, being extended, continue their extensions in such a manner, as that the part seems immoveable, though in reality it be in motion.

**TONNAGE**, or **TUNNAGE**. See the article **TUNNAGE**.

**TONSILS**, *Tonsillæ*, in anatomy, two remarkable glands, situated one on each side of the mouth, near the uvula, and commonly called almonds of the ears, from their resembling almonds in figure.

Their use is to secrete a mucous humour, for lubricating the passages: this they discharge by several irregular but conspicuous foraminæ into the mouth.

**TONSURE**, in ecclesiastical history, a particular manner of shaving or clipping the hair of ecclesiastics, or monks.

**TOOL**, among mechanics, denotes in general any small instrument, used as well for making other more complex instruments and machines, as in most operations in the mechanic arts.

**TOOTH**, *Dens*, in anatomy, a little, very hard, and smooth bone, fixed in a proper alveolus or socket in the jaw, in the manner of a nail; and serving to masticate or chew the food.

The natural colour of the teeth, in mankind, is white; and their number, from twenty-eight to thirty-two; fourteen, fifteen, or sixteen, being placed in each jaw, if the number be perfect. The teeth are usually divided into the four incisores, or fore-teeth; the two canine, eye-teeth, or dog-teeth; the eight molares, or grinders, in each jaw, and two *dentes sapientia*.

The bodies of the teeth are composed of a double substance, a stony or porcelain-like matter, and a medullary one: their roots are sometimes simple, as in the incisores, canini, and foremost of the molares; and sometimes double, triple, or quadruple, as in the hinder molares.

The cavities of the teeth are covered with a vasculo-nervous membrane, and the foraminula, or little holes, in the ends of them, serve for the ingress of the vessels which afford them nutrition and sensation.

For the breeding of the teeth, in infants, see the article DENTITION.

As to the cleansing of foul teeth, see the article DENTIFRICE.

Fossile teeth of fishes are known by three names; the glossopetræ, the bufonitæ, and the plectronitæ. See the articles GLOSSOPETRÆ, BUFONITÆ, and PLECTRONITÆ.

TOOTH-ACH, *οδονταλγία*, a very painful disorder, caused by an impure serum which corrodes and rends the ligaments and nervo-glandulous coats, by which the teeth are kept firm in their sockets: its seat may also be in the cavity or internal parts of the teeth themselves.

The whole intension of cure, in this disorder, consists in deriving and diverting the impure scorbutic serum from the head, and then carrying it off by proper emunctories. This is to be done by saline, emollient, and purgative clysters; by warm pedeluvia of rain-water and wheat-bran, with Venice-soap, used just before bed-time; by laxatives of manna and cassia dissolved in whey or asses-milk, or mineral waters: if the patient is plethoric, or full of blood, phlebotomy in the foot will be proper, to derive the humours from the head. Sudorific remedies are also proper, but more especially an electuary made of rob of elder-berries, burnt hart's-horn, diaphoretic antimony, and a few grains of nitre: or, an ounce of the rob may be taken in broth, to promote a diaphoresis; and it may be used externally, dissolved in beer, in the manner of a gargle, which will yield immediate relief to the patient.

When the patient is subject to catarrhs, is scorbutic or cachectic, then mineral waters are most proper; and if the patient is of a weak bilious constitution, the water should be mixed with asses-milk.

Outwardly, may be applied bags, filled with pargoric and emollient species; such as elder, melilot, and camomile flowers, bay and juniper-berries, carraway and millet-seeds, and decrepitated salt: they must be laid on warm, and are very safe. A drop or two of oil of cloves or box, applied to a carious tooth with cotton, are medicines not to be despised; and camphorated spirits of wine, mixed with saffron, castor, and opium, made into a liniment, and laid to the gums and hollow tooth, often gives the patient ease.

When the tooth-ach proceeds from a rotten hollow tooth, it will be best to burn the little nervous cord, which is the seat of the pain, with an acute cautery; and then the cavity may be filled up with a mixture of wax and mastich. But if this cannot

be done, the only remedy left is to have the tooth drawn.

Allen advises, to rub the tooth that is painful, with the root of the iris lutea, or the yellow fleur-de-luce; or a pill may be made of equal quantities of camphor or opium, and put into the hollow tooth; and, lastly, some greatly recommend a small plaster of tacamalzac, laid on the side of the face.

TOPARCHY, a little state or seigniory, consisting only of a few cities or towns; or a petty country, governed and possessed by a toparch, or lord. See GOVERNMENT.

TOPAZ, in natural history, a gem called by the ancients chrysolite, as being of a gold-colour. See GEM.

The topaz, when perfect and free from blemishes, is a very beautiful and valuable gem; it is, however, very rare in this state. It is of the number of those gems which are found only in the round or pebble form, there never having been yet seen a true and genuine topaz of a columnar figure, though the far greater part of what our jewellers call such, are in that form.

The greatest part of the true topazes are no larger than grains of a coarse seed; among these there are, however, some met with of the size of a pea, and some much larger, though those are very rare.

It is of a roundish or oblong figure in its native or rough state, and usually is flatted on one side, and is generally of a bright and naturally polished surface, tolerably transparent. They are ever of a fine yellow colour; but they have this, like the other gems, in several different degrees; the finest of all are of a true and perfect gold-colour, but there are some much deeper, and others extremely pale, so as to appear scarce tinged. The original topaz is equal to the ruby in hardness, and is second only to the diamond in lustre. The topazes of the other parts of the world fall off greatly from this hardness, but the purest of the genuine ones are considerably harder than crystal.

The topaz, on being thrown into a charcoal fire, entirely loses its colour, and when taken out, is a very fine colourless stone, undistinguishable from that known by the name of the white sapphire: upon the whole, it appears, that the oriental coloured gems are all much alike in their matter, differing scarce at all, except in colour, and that when they are found either naturally colourless, or rendered so by art, it is not easy to distinguish one of them from the other.

The finest topazes in the world are found in the East-Indies, but they are very rare there of any great size: the great mogul, however, at this time, possesses one, which is said to weigh a hundred and fifty-seven carats, and to be worth more than twenty thousand pounds. The topazes of Peru come next, after these, in beauty and in value. The

European

European are principally found in Silesia and Bohemia, and are generally full of cracks and flaws, and of a brownish yellow.

**TOPHUS**, in medicine, denotes a chalky or stony concretion in any part of the body, as the bladder, kidneys, &c. but especially in the joints. See **GOUT**.

**TOPIC**, in rhetoric, denotes a probable argument, drawn from the several circumstances of a fact, &c.

**TOPICS**, or **TOPICAL MEDICINES**, are the same with external ones, or those applied outwardly to some diseased and painful part: such are plasters, cataplasms, unguents, &c. See the articles **PLASTER**, &c.

**TOPOGRAPHY**, a description or draught of some particular place, or small tract of land, as that of a city or town; manor or tenement, field, garden, house, castle, or the like; such as surveyors set out in their plots, or make draughts of, for the information and satisfaction of the proprietors.

**TORCH-THISTLE**, *Cereus*, or *Cactus*, in botany. See **CEREUS**.

**TORDYLIUM**, hart-wort, in botany, a genus of umbelliferous plants, whose general corolla is difform and radiated; the particular flowers of the disc consist each of five inflexed heart-shaped petals, which are equal; those which form the radius are like the others, except the outward petals, which are largest and bipartite: the fruit is roundish and compressed, longitudinally indented, dividing into two parts, each containing a roundish compressed seed, with an indented margin.

The roots of the common hart-wort are accounted good in a moist asthma, and to promote expectation; but it is very little used in the present practice.

**TORE**, *Torus*, in architecture, a large round moulding, used in the bases of columns. See the article **MOULDING**.

**TORENIA**, in botany, a genus of didynamious plants, whose flower is monopetalous and ringent; the upper lip is intire, and the lower one trifid, with the middle segment drawn out in length; the germen is oblong, the style slender, and crowned with a bifid acute stigma: the fruit is an oblong bilocular capsule, which contains many seeds.

**TOREUMATOGRAPHY**, a Greek term, signifying the knowledge, or rather description, of ancient sculptures and basso-relievos.

**TOREUTICE**, *torpeuln*, that part of sculpture otherwise called turning. See the article **TURNING**.

**TORIES**, or **TORYS**, in the history of England, a faction, or party, opposed to the whigs.

The Tories are great sticklers for the prerogative of the crown, as the whigs are for the liberties and privileges of the people: though, in truth, the

principles of the moderate people of both parties do not greatly differ. See the article **WHIGS**.

**TORMENTIL**, *Tormentilla*, in botany, a genus of plants, whose flower hath four oval, heart-shaped, patent petals, with their ungues inserted into the cup: the stamina consist of sixteen subulated filaments, half the length of the corolla, inserted into the cup, and topped with single antheræ: the germina are eight in number, collected into a head, which afterwards become so many oblong obtusely-acuminated seeds, and contained in the cup.

The common tormentil has a root about the thickness of a man's finger; it is rough, unequal, sometimes straight, and sometimes crooked, of a dark colour without, and reddish within: the stalks are slender, weak, hairy, and reddish, about a foot long, and surrounded with leaves by intervals, which are hairy. It grows in dry pastures and commons in most parts of England, and flowers in May, June, or July.

The root has been frequently used for tanning of leather, in places where oak bark is scarce: it has an austere styptic taste, accompanied with an aromatic flavour, and is one of the most agreeable and efficacious astringents in the whole vegetable kingdom: there are also a tincture and a distilled water of it, the former of which possesses all the virtues of the simple.

**TORMINA**, the gripes, in medicine. See the article **COLIC**.

**TORNADO**, or **TURNADO**, a sudden and vehement gust of wind from all points of the compass, frequent on the coast of Guinea. See the articles **HURRICANE** and **WHIRLWIND**.

**TORPEDO**, the cramp or numb fish, in ichthyology, a species of raia, the body of which is perfectly smooth, and considerably broad in proportion to its length; the rostrum, or snout, is oblong and subacute; the back is somewhat gibbose; the belly is flat, and the sides are terminated by broad fins; its colour on the back is a dusky greyish, and the belly is white.

The most singular property of this fish is, that, when out of the water, it affects the hand or other part that touches it, with a sensation much like that which we call the cramp; the shock is instantaneous, and resembles that given by electricity, only that the effect lasts longer: this is all the fish can do; but those who have related it, have raised the effects almost into miracles. Reaumur has given a long memoir, wherein he endeavours to account for this singular phenomenon, which he resolves into the instantaneous action of a vast multitude of small muscles on the surface of the body of the fish: but there seems something more required, in order to the perfectly explaining so odd an effect.

**TORQUE**, in heraldry, denotes a round roll of cloth, twisted and stuffed; such is the bandage, frequently

quently seen in armories, about the heads of Moors, &c. It is always of the two principal colours of the coat; and is accounted the least honourable decoration worn on the helmet, by way of crest.

**TORREFACTION**, in chemistry, is the roasting or scorching of a body by the fire, in order to discharge a part either unnecessary or hurtful in another operation; as sulphur is thus discharged from an ore, before the metal can be obtained to advantage.

**TORRENT**, *Torrens*, in geography, denotes a temporary stream of water, falling suddenly from mountains, whereon there have been great rains, or an extraordinary thaw of snow.

**TORRICELLIAN EXPERIMENT**, a famous experiment made by Torricelli, a disciple of the great Gallileo, which has been already explained under the article **BAROMETER**; which see.

**TORRID ZONE**, among geographers, denotes that tract of the earth lying upon the equator, and on each side as far as the two tropics, or  $23^{\circ} 30'$  of north and south latitude.

The torrid zone was believed, by the ancients, to be uninhabitable; but is now well known to be not only inhabited by the natives of those hot climates, but even tolerable to the people of the colder climates, towards the north and south; the excessive heat of the day being there tempered by the coldness of the night.

**TORTOISE**, *Tesludo*, in zoology. See the article **TESTUDO**.

**TORTURE**, a grievous pain inflicted on a criminal, or person accused, to make him confess the truth.

**TOUCAN**, in ornithology, a species of *ramphastos*, of a middle size between our common magpie and the thrush, but having a beak thicker and longer than its whole body: this beak is hooked at the end, and is of a very thin substance, not exceeding the thickness of a membrane, and very light and hollow, yet bony in substance, and very bright and shining. It has a sort of toothed edge, which prevents its shutting closely, and, giving passage for the air, enables the bird to live without nostrils. It is yellowish on the outside and red within, and is covered with a sort of scaly substance, easily scraped off with the finger at the edge.

The head of this bird is large in proportion to its body, and is black on the crown; the rest of it, and the neck and back, are slightly variegated with white; its breast is of a bright orange colour, its belly and thighs of a very fine and bright red, and the tail is black, but red at the end.

**TOUCAN**, in astronomy, a constellation of the southern hemisphere, consisting of eight small stars, and otherwise called *Anser Americanus*.

**TOUCH-NEEDLE**, among assayers, refiners, &c. little bars of gold, silver, and copper, combined

together in all the different proportions and degrees of mixture; the use of which is to discover the degree of purity of any piece of gold or silver, by comparing the mark it leaves on the touch-stone, with those of the bars.

The metals usually tried by the touch-stone, are gold, silver, and copper, either pure, or mixed with one another in different degrees and proportions, by fusion.

In order to find out the purity or quantity of baser metal in these various admixtures, when they are to be examined, they are compared with these needles, which are mixed in a known proportion, and prepared for this use. The metals of these needles, both pure and mixed, are all made into laminæ, or plates, one-twelfth of an inch broad, and of a fourth part of their breadth in thickness, and an inch and half long; these being thus prepared, you are to engrave on each a mark indicating its purity, or the nature and quantity of the admixture in it.

The black rough marbles, the basaltæ, or the softer kinds of black pebbles, are the most proper for touch-stones.

Now, the method of using the needles and stone is this: The piece of metal to be tried, ought first to be wiped well with a clean towel, or piece of soft leather, that they may the better see its true colour; for from this alone an experienced person will, in some degree, judge before-hand what the principal metal is, and how, and with what, debased.

Then chuse a convenient, not over large, part of the surface of the metal, and rub it several times very hardly and strongly against the touch-stone, that in case a deceitful coat or crust should have been laid upon it, it may be worn off by that friction; this, however, is more readily done by a grind-stone, or small file, if you have them at hand. Then wipe a flat and very clean part of the touch-stone, and rub against it, over and over, the just mentioned part of the surface of the piece of metal, till you have, on the flat surface of the stone, a thin metallic crust, an inch long, and about an eighth of an inch broad: this done, look out the needle that seems most like to the metal under trial, wipe the lower part of this needle very clean, and then rub it against the touch-stone, as you did the metal, by the side of the other line, and in a direction parallel to it.

When this is done, if you find no difference between the colours of the two marks, made by your needle and the metal under trial, you may with great probability pronounce that metal and your needle to be of the same alloy, which is immediately known by the mark engraved on your needle. But if you find a difference between the colour of the mark given by the metal, and that by the needle you have tried, choose out another needle, either of a darker or lighter colour than the former, as the difference of the tinge on the touch-stone directs; and

and by one or more trials of this kind you will be able to determine which of your needles the metal answers, and thence what alloy it is of, by the mark of the needle; or else you will find that the alloy is extraordinary, and not to be determined by the comparison of your needles.

**TOUR**, a French term, frequently used for a journey or progress through one or more countries.

**TOURNEFORTIA**, in botany, a genus of plants, whose flower-cup is small, and divided into five segments; the corolla is monopetalous and funnel-shaped, the tube of which is cylindric and globular at the base, and the limb is divided into five acute segments, which spread open horizontally: the fruit is a globose succulent berry, containing four oblong oval seeds, separated by the pulp.

This genus is the same with the pittonia of Plumier.

**TOURNEQUET**, in surgery, an instrument made of rollers, compresses, screws, &c. for compressing any wounded part, so as to stop hæmorrhages.

The common tournequet is very simple, consisting only of a roller, which, with the help of a small stick, serves to stop the effusion of blood from large arteries, in amputations, by forcibly tying up the limb. The things necessary for this are a roller, of a thumb's breadth, and of an ell in length, a small cylindrical stick, a conglomerated bandage, two fingers thick and four long, some compresses of a good length and about three or four fingers breadth, to surround the legs and arms, and a square piece of strong paper or leather, about four fingers wide.

**TOWER**, *Turris*, a tall building, consisting of several stories, usually of a round form, though sometimes square or polygonal.

**TOWN**, a place inhabited by a considerable number of people, being of a middle size between a city and a village.

**TOXICODENDRON**, the poison-tree, in botany, a genus producing male and female flowers on different plants; the male flowers have five small roundish petals, which spread open, with the same number of stamina; the female flower is like the male, excepting the deficiency of the stamina, instead of which, it contains three small styles, crowned with globular stigmata; and the fruit is a smooth striated berry, containing a compressed furrowed kernel or seed.

This genus is included by Linnæus among the sumachs. See the article **RHUS**.

There are several species of toxicodendron; the wood of some of them, when burnt, emits a noxious fume, which will suffocate animals when they are shut up in a room where it is burning; the scent of it, when cut down in the woods, has poisoned many people, and several, with only handling it, have been made blind for several days. The juice of the tree is milky when it first issues out of the wounded

part, but soon after it is exposed to the air it turns black, and has a very strong foetid scent, and will even corrode iron.

**TOZZIA**, in botany, a genus of plants, whose flower is monopetalous and ringent; the tube is cylindraceous, and longer than the cup; the limb is patent; the upper-lip bifid, and the lower one trifid, and all the edges are almost equal and roundish: the fruit is a globose unilocular capsule, containing a single egg-shaped seed.

**TRACHEA**, in anatomy, called also *aspera arteria*, and in English the wind-pipe, is a tube or canal, extended from the mouth to the lungs; its situation is in the middle and anterior part of the neck; and it is connected with the fauces, the lungs, and the œsophagus. Anatomists commonly divide it into two parts, the larynx, and *aspera arteria* properly so called. See the article **LARYNX**.

The trachea, or *aspera arteria* properly so called, is that whole cartilaginous canal, extended from the larynx, which is only its mouth or entrance, to the bronchia or lungs; being, in some measure, of a conic figure. Its beginning is cylindrical, and capable of admitting a finger; and its other end is somewhat narrower. It enters the thorax under the sternum, and is there divided into two branches, before it enters the lungs: it is composed of eighteen or nineteen, sometimes but sixteen, sometimes twenty, cartilaginous rings, and four coats. These rings are imperfect, the hinder part of the trachea being membranaceous. Of the four coats, the exterior is membranaceous, the second glandulous, the third muscular, and the fourth or internal covering is tendinous and robust.

The uses of the trachea are, to assist in deglutition, and to be assistant to the lungs: on the exterior part of it are the thyroide and bronchial glands, which secrete an humour to moisten it: its arteries are from the external carotids, the veins from the jugulars, and the nerves from the recurrent ones of the plexus cervicalis.

The tracheæ of vegetables are certain air-vessels, discernible in many plants, but in none more distinctly than the melon.

**TRACHELIUM**, umbelliferous throat-wort, in botany, a genus of plants, whose flower is monopetalous and funnel-shaped; the tube is very long, slender, and cylindric; the limb is small, and divided into five ovate concave segments; the fruit is a roundish, obtuse, trilocular capsule, containing one or more cells, which are filled with many small seeds.

**TRACHEOTOMY**, in surgery, the name of an operation otherwise called bronchotomy. See **BRONCHOTOMY**.

**TRACT**, in geography, an extent of ground, or a portion of the earth's surface.

**TRACT**, in matters of literature, denotes a small treatise, or written discourse, upon any subject.

**TRAC-**

**TRACTION**, the act of drawing, whereby a thing is brought nearer to the mover.

**TRACTRIX**, in geometry, a curve otherwise called *catenaria*. See **CATENARIA**.

**TRADE**, in general, denotes the same with commerce, consisting in buying, selling, and exchanging of commodities, bills, money, &c.

**TRADE-WINDS**, denote certain regular winds at sea, blowing either constantly the same way, or alternately this way and that; thus called from their use in navigation, and the Indian commerce.

The trade-winds are of different kinds, some blowing three or six months of the year one way, and then the like space of time the opposite way; these are very common in the Indian seas, and are called monsoons. See the article **MONSOONS**.

Others blow constantly the same way; such is that general wind between the tropics, which off at sea, is found to blow all day long from east to west. For the phenomena of each, with their physical causes, see the article **WIND**.

**TRADESCANTIA**, Virginia spider-wort, in botany, a plant whose root is composed of several fleshy fibres, from which arise several long, narrow, keel-shaped leaves, which are veined, rough on their edges, of a greyish colour, and succulent; between the leaves arises a thick jointed stalk about a foot long, furnished at each joint with one leaf; at the top of the stalk are two leaves which spread asunder; the flowers come out in a kind of umbel, each formed of a triphyllous cup with three large roundish petals of a deep blue colour, which in the morning spread open, but shrink up in the middle of the day, and do not open again; the stamina consist of six slender hairy filaments, topped with reniform antheræ; the fruit is an oval capsule, having three angles, and shut up in the cup, and includes a few angular seeds contained in three cells.

The root of this plant is perennial, and it is propagated by sowing its seeds when ripe. This is the same with the *epheumerum* of Tournefort.

**TRADITION**, among ecclesiastical writers, denotes certain regulations regarding the rites, ceremonies, &c. of religion, which we suppose to have been handed down from the days of the apostles, to the present time.

Tradition is distinguished into written, whereof there are some traces in the writings of the ancient fathers; and unwritten, whereof no mention is made in the writings of the first ages of Christianity.

**TRAGACANTHA**, goats-thorn, in botany, a genus of plants, whose flower is papilionaceous; the vexillum is long, erect, indented at the point, and the borders reflexed; the wings are oblong, and shorter than the vexillum, and the carina is the length of the wings, and emarginated; the stamina consists of ten filaments, nine of which are

joined together, these are topped with roundish anthers; the fruit is a short swelling pod, having two longitudinal cells, which contain kidney-shaped seeds.

This genus is included by Linnæus among the *astragalus*. See **ASTRAGALUS**, **GUM**, &c.

Gum-tragacanth, or, as some call it, gum-adragant, or gum-dragon, is the produce of this shrub, which grows to about four feet high, and has a firm and robust stem, with numerous branches.

The gum is brought to us in long and slender pieces, of a flattened figure, more or less, and these not straight, or rarely so; but commonly twisted and contorted various ways, so as to resemble worms. We sometimes meet with it like the other vegetable exsudations, in roundish drops, but these are much more rare. It is moderately heavy, of a firm consistence, and, properly speaking, very tough rather than hard, and is extremely difficult to powder, unless first carefully dried, and the mortar and pestle kept warm. Its natural colour is a pale whitish, and in the cleanest pieces it is something transparent. It is often, however, met with tinged brownish, and of other colours, and more opaque. It has no smell, and very little taste, but what it has is disagreeable. Taken into the mouth, it does not grow clammy, and stick to the teeth, as the gum-arabic does, but melts into a kind of very soft mucilage. It dissolves in water but slowly, and communicates its mucilaginous quality to a great quantity of that fluid. It is brought to us from the island of Crete, and from several parts of Asia. It is to be chosen in long twisted pieces, of a whitish colour, very clear, and free from all other colours; the brown, and particularly the black, are wholly to be rejected.

Tragacanth has the same virtues with gum-arabic, but in a greater degree. It greatly inspissates and obtunds the acrimony of the humours, and is therefore found of vast service in inveterate coughs, and other disorders of the breast, arising from an acrid phlegm, and in stranguries, heat of urine, and all other complaints of that kind. It is usually given in the compound powder, called the species *diatragacantha frigidæ*, rarely alone. It is also, by some, esteemed a very great external remedy for wounds, and in this sense made an ingredient in some sympathetic powders, with vitriol and other things. It is by some recommended alone, in form of a powder or strong mucilage, for cracks and chaps in the nipples of women: but it is found, by experience, to be a very troublesome application in those cases, and to do more harm than good, as it dries by the heat of the part, and draws the lips of the wound farther asunder than before.

**TRAGEA**, in pharmacy, an aromatic powder, grossly beaten and mixed with sugar, taken by way of carminative.

**TRAGEDY**, a dramatic poem, representing some

some signal action performed by illustrious persons, and which has frequently a fatal issue, or end.

Aristotle, more scientifically, defines tragedy, the imitation of one grave and entire action, of a just length, and which, without the assistance of narration, by raising of terror and compassion, refines and purges our passions. This definition has given the critics some perplexity; and Corneille declares he cannot reconcile Aristotle with himself: the instances Aristotle cites, he thinks, ruin his own definition; he even denies the purging our passions to be the end of tragedy. Our English authors are more favourable to the definition; by the purging our passions, they understand not the extirpating them, but the reducing them to just bounds; for by shewing the miseries that attend a subjection to them, it teaches us to watch them more narrowly; and by seeing the great misfortunes of others, it lessens the sense of our own.

Tragedy, in its original, M. Hedelin observes, was only a hymn sung in honour of Bacchus, by several persons, who, together, made a chorus of music, with dances and instruments. As this was long, and might fatigue the fingers, as well as tire the audience, they bethought themselves to divide the singing of the chorus into several parts, and to have certain recitations in the intervals. Accordingly Thespis first introduced a person upon the stage with this view. Æschylus, finding one person insufficient, introduced a second, to entertain the audience more agreeably, by a kind of dialogue: he also clothed his persons more decently, and first put on them the buskin.

The persons who made these recitations on the scene, were called actors; so that tragedy was at first without actors. And what they thus rehearsed, being things added to the singing of the chorus, whereof they were no necessary part, were called episodes.

Sophocles found that two persons were not enough for the variety of incidents, and accordingly introduced a third; and here the Greeks seemed to have stopped; at least, it is very rare that they introduced four speakers in the same scene.

Tragedy and comedy were, at first, confounded with each other, but were afterwards separated; and the poets applied themselves to the cultivating of tragedy, neglecting comedy. See the article COMEDY.

When tragedy was got into a better form, they changed the measure of its verse, and endeavoured to bring the action within the compass of a day, or of a revolution of the sun.

The English received the first plan of their drama from the French, among whom it had its rise towards the end of Charles V. under the title of chant-royal, which consisted of pieces in verse, composed in honour of the Virgin, or some of the

saints, and sung on the stage: they were called by the title of chant-royal, because the subject was given by the king of the year, or the person who had borne away the prize the year preceding.

The humour of these pieces ran wonderfully among the people, insomuch that in a little time there were formed several societies, who began to vie with each other: one of these, to engage the town from the rest, began to intermix various incidents or episodes, which they distributed into acts, scenes, and as many different persons as were necessary for the representation. Their first essay was in the Bourg St. Maur, and their subject the passion of our Saviour. The provost of Paris prohibiting their continuing of it, they made application to court; and to render it the more favourable to them, elected themselves into a friary or fraternity, under the title of Brothers of the passion: which title has given some occasion to suspect them to have been an order of religious. The king, on seeing and approving some of these pieces, granted them letters of establishment, in 1402; upon which they built a theatre, and for an age and a half acted none but grave pieces, till, the people growing weary of them, they began to intermix farces, or interludes, from prophane subjects.

The mixing of farce and religion displeasing many, they were re-established by an arret of parliament, in 1548, on condition of their acting none but proper, lawful, and decent subjects, without intermeddling with any of the mysteries of religion; and thus were the brothers of the passion despoiled of their religious character: upon which they mounted the stage no more in person, but brought up a new set of comedians, who acted under their direction.

Thus was the drama established, and on this foundation arrived in England. In process of time, as it was improved, it became divided into two branches, agreeable to the practice of the ancients, and the nature of things, viz. into tragedy and comedy, properly so called; and this last again was subdivided into pure comedy and farce. See the articles COMEDY and FARCE.

TRAGI-COMEDY, a dramatic piece partaking of the nature both of tragedy and comedy, the event whereof is not bloody or unhappy, and wherein is admitted a mixture of less serious characters.

The foundation of tragi-comedy is certainly bad; for endeavouring to make us laugh and cry by turns, it endeavours at contrary motions, which the heart can never undergo; every thing that disposes for the one, indisposes for the other: for which reason it is at present, with great justice, disused. However, tragi-comedy is the only way wherein comedy is allowed to introduce kings and heroes.

TRAGIA, in botany, a genus of plants, producing male and female flowers on the same stalk; neither

neither has any corolla; the male flower consisting of a cup divided into three oval, acute, patent segments, with three filaments topped with roundish antheræ; the cup of the female flower is persistent, and divided into five parts; it contains a roundish three furrowed germen, with an erect style, crowned with a trifid spreading stigma; the fruit is a roundish hispid capsule, having three cells, each containing a globose seed.

**TRAGOPOGON**, goats-beard, in botany, a genus of plants, whose flower is compound, imbricated, and uniform, consisting of a number of ligulated floscules, quinque-dentated at the ends; there is no pericarpium, but the seeds, which are oblong, angulated, rough, and crowned with a plumose down, are contained in the cup, and placed on a scabrous, naked, flat receptacle.

This genus includes the *salsafy*. See the article **SALSIFY**.

**TRAGOSELINUM**, in botany, Tournefort's name for the *pimpinella* of Linnæus. See the article **PIMPINELLA**.

**TRAGUS**, *τραγος*, in anatomy, one of the protuberances of the auricle, or external ear, called also *hircus*, because usually hairy. The *tragus* is that protuberance next the temple: that on the opposite side, to which the soft lobe of the ear is annexed, is called the *antitragus*. See the article **EAR**.

**TRAJAN COLUMN**, a famous historical column erected in Rome, in honour of the emperor Trajan. It is of the Tuscan order, though something irregular; its height is eight diameters, and its pedestal Corinthian: it was built in a large square there, called *Forum Romanum*. Its base consists of twelve stones, of an enormous size, and it is raised on a socle, or foot of eight steps; with-inside is a stair-case, illuminated with forty-four windows. It is 140 feet high, which is thirty-five short of the Antonine column, but the workmanship of the former is much more valued. It is adorned from top to bottom with basso relievos, representing the great actions of that emperor against the *Dacæ*.

**TRAJECTORY** of a *Comet*, is its path or orbit, or the line it describes in its motion. See the article **COMET**.

**TRAIL-BOARD**, in a ship, a carved board on each side of her beak, which reaches from the main stem to the figure, or the brackets.

**TRAIN**, the attendance of a great person, or the trail of a gown, or robe of state.

In falconry, it denotes the tail of an hawk.

**TRAIN**, is likewise used for the number of beats which a watch makes in an hour, or any other certain time.

**TRAIN**, is also used for a line of gun-powder, laid to give fire to a quantity thereof, in order to

do execution by blowing up earth, works, buildings, &c.

**TRAIN**, or **TRAILE** of *Artillery*, includes the great guns, and other pieces of ordnance belonging to an army in the field. See the article **CANNON**.

**TRAIN-OIL**, the oil procured from the blubber of a whale by boiling.

**TRAIN-BANDS**, or **TRAINED-BANDS**, a name given to the militia of England.

**TRAINING**, or **TRACING**, in mineralogy, a term used by the miners, to express the tracing up the mineral appearances on the surface of the earth to their head, or original place, and there finding a mine of the metal they contain. See the article **MINE**.

**TRAMBLING** of *Tin Ore*, among miners, the washing it very clean, which is done in a shovel, and in a frame of boards. See the article **TIN**.

**TRAMEL**, an instrument, or device, sometimes of leather, more usually of rope, fitted to a horse's legs, to regulate his motions, and form him to an amble. It is also taken in many places for an iron moveable instrument in chimnies to hang pots over the fire.

**TRANSACTION**, *Transactio*, in the civil law, an accommodation of some business, or dispute between two parties, by a mutual and voluntary agreement between them. See the article **ACCOMMODATION**.

*Philosophical* **TRANSACTIONS**, a kind of journal of the principal things that come before the Royal Society. See the article **SOCIETY**.

**TRANSCENDENTAL**, or **TRANSCENDANT**, something elevated, or raised above other things; which passes and transcends the nature of other inferior things.

Transcendental quantities, among geometricians, are indeterminate ones, or such as cannot be fixed or expressed by any constant equation: such are all transcendental curves, which cannot be defined by any algebraic equation: or which, when expressed by an equation, one of the terms thereof is a variable quantity. Now whereas algebraists use to assume some general letters or numbers, for the quantity sought in these transcendental problems, Mr. Leibnitz assumes general or indefinite equations for the lines sought; e. gr. putting  $x$  and  $y$  for the absciss and ordinate, the equation he uses for a line is  $a + bx + cy + exy + fxx + gyy$ , &c.  $= 0$ , by the help of which indefinite equation, he seeks the tangent; and by comparing the result with the given property of tangents, he finds the value of the assumed letters  $a, b, c, d$ , &c. and thus defines the equation of the line sought.

If the comparison above-mentioned, do not proceed, he pronounces the line sought, not to be an algebraical, but a transcendental one. This supposed,

posed, he goes on to find the species of transcendency; for some transcendentals depend on the general division or section of a ratio, or upon the logarithms; others, upon the arcs of a circle; and others, upon more indefinite and compound inquiries.

He, therefore, besides the symbols  $x$  and  $y$ , assumes a third, as  $v$ , which denotes the transcendental quantity; and of these three, forms a general equation for the line sought, from which he finds the tangent, according to the differential method, which succeeds even in transcendental quantities.

The result he compares with the given properties of the tangent, and so discovers, not only the values of  $a$ ,  $b$ ,  $c$ ,  $d$ , &c. but also the particular nature of the transcendental quantity. And though it may sometimes happen, that the several transcendentals are so to be made use of, and those of different natures too, one from another; also, though there be transcendentals of transcendentals, and a progression of these in infinitum, yet we may be satisfied with the most easy and useful one; and for the most part, may have recourse to some peculiar artifices for shortening the calculus, and reducing the problems to as simple terms as may be.

This method being applied to the business of quadratures, or to the invention of quadratics, in which the property of the tangent is always given, it is manifest, not only how it may be discovered, whether the indefinite quadrature may be algebraically impossible; but also, how, when this impossibility is discovered, a transcendental quadratrix may be found, which is a thing not before shewn. So that it seems, that geometry, by this method, is carried infinitely beyond the bounds to which Vieta and Des Cartes brought it; since, by this means, a certain and general analysis is established, which extends to all problems of no certain degree, and consequently not comprehended within algebraical equations.

Again, in order to manage transcendental problems, wherever the business of tangents or quadratures occurs, by a calculus, there is hardly any thing that can be imagined shorter, more advantageous, or more universal, than the differential calculus, or analysis of indivisibles and infinites. By this method, we may explain the nature of transcendental lines, by an equation; e. gr. let  $a$  be the arch of a circle, and  $x$  the versed line; then will

$a = \frac{Sdx}{\sqrt{2x-xx}}$ ; and if the ordinate of the cycloid be

$y$ , then will  $y = \sqrt{2x-xx} + \frac{Sdx}{\sqrt{2x-xx}}$ ; which

equation perfectly expresses the relation between the ordinate  $y$  and the absciss  $x$ , and from it all the properties of the cycloid may be demonstrated.

Thus is the analytical calculus extended to those

lines, which have hitherto been excluded; for no other reason, but that they were thought incapable of it.

**TRANSCRIPT**, a copy of any original writing, particularly that of an act, or instrument, inserted in the body of another.

**TRANSFER**, in commerce, &c. an act whereby a person surrenders his right, interest, or property, in any thing moveable or immoveable to another.

The term transfer, is chiefly used for the assigning and making over shares in the stocks, or public funds, to such as purchase them of the proprietors.

**TRANSFORMATION**, in general, denotes a change of form, or the assuming a new form different from a former one.

The chemists have been for a long time seeking the transformation of metals; that is, their transmutation, or the manner of changing them into gold. See the article **TRANSMUTATION**.

**TRANSFORMATION of Equations**. The doctrine of the transformation of equations, and of exterminating their intermediate terms, is thus taught by Mr. Mac Laurin. The affirmative roots of an equation are changed into negative roots of the same value, and the negative roots into affirmative, by only changing the signs of the terms alternately, beginning with the second. Thus, the roots of the equation,  $x^4 - x^3 - 19x^2 + 49x - 30 = 0$ , are  $+1$ ,  $+2$ ,  $+3$ ,  $+4$ ,  $-5$ ; whereas the roots of the same equation having only the signs of the second and fourth terms changed, viz.  $x^4 + x^3 - 19x^2 - 49x - 30 = 0$ , are  $-1$ ,  $-2$ ,  $-3$ ,  $+5$ .

**TRANSFUSION**, *Transfusio*, the act of pouring a liquor out of one vessel into another.

**TRANSFUSION of the Blood**, in surgery, the conveying of the arterial blood of one man, or animal, into the veins of another.

Notwithstanding injections and transfusions are seldom practised by our modern surgeons, they were highly celebrated, and often performed in the last century.

The generality of physicians, not without reason, attribute most disorders of the body to some vice in the blood; and, therefore, some were led to think, that no method could be more ready to remove and correct that vice, than injecting a proper medicine in the veins to mix with the blood itself, or the transfusing the sound blood of one animal into the veins of another, instead of that which is diseased. But, notwithstanding the vast expectations which had been formed by physicians from this operation, frequently the event turned worse than the disease; for we are told, that almost all the patients who have been treated this way, degenerated into a stupidity, foolishness, or a raving, or melancholy madness, or have been taken off with a sudden death, either in, or not long after, the operations.

For the transfusion of blood into the veins, first,

a vein is to be opened in the patient's arm, or hand, and then a small tube of silver, brass, or ivory, thrust upward into it: the same is to be done with the sound person, only the tube must here be inserted downward, toward the small end of the vein; this done, the smallest of the tubes is to be inserted into the other larger one; by which means, as much blood will pass from the sound person into the patient, as may be thought proper, and then the incised veins are to be dressed, or bound up, as in bleeding: if the patient does not recover after the first transfusion, the operation should be repeated again, at convenient intervals; but before the patient receives the blood of the sound person, he ought to be bled proportionably, that the new blood last received, may have the freer circulation. Sometimes a vein is opened in each arm of the patient at the same time, that as much of the vitiated blood may flow out of one orifice, as he receives of the sound by the other.

If the blood is to be transfused out of some animal into the patient, then a calf or a lamb, for example, is to be secured by ligatures, and one of their veins or arteries opened in the neck, leg, or thigh, and the rest of the operation managed as before.

**TRANSIT**, *Transitus*, in astronomy, signifies the passage of any planet, just by, or over a fixed star, or the sun, and of the moon in particular, covering or moving over any planet.

**TRANSITION**, in music, is when a greater note is broken into a less, to soften the roughness of a leap by a gradual passage to the next note following; whence it is commonly called, the breaking of a note.

**TRANSITION**, in rhetoric, is of two sorts; the first is when a speech is introduced abruptly, without express notice given of it; as when Milton gives an account of our first ancestors' evening devotions.

Both turn'd, and under open sky ador'd  
The God that made both air, sky, earth, and  
heav'n.—  
—Thou also mad'st the night,  
Maker omnipotent, and thou the day!

The second sort of transition is, when a writer suddenly leaves the subject he is upon, and passes unto another, from which it seems different at first view, but has a relation and connection with it, and serves to illustrate and enlarge it.

**TRANSITIVE**, in grammar, an epithet applied to such verbs as signify an action which passes from the subject that does it, to or upon another subject which receives it.

Under the head of verbs transitive, come what we usually call verbs active and passive; other verbs, whose action does not pass out of themselves, are called neuters, and by some grammarians, intransitives.

**TRANSLATION**, the act of transferring or removing a thing from one place to another; thus we say, the translation of a bishop's see, a council, a feat of justice, &c.

**TRANSLATION**, is also used for the version of a book, or writings, out of one language into another.

**TRANSMARINE**, something that comes from, or belongs to, the parts beyond sea.

**TRANSMIGRATION**, the removal or translation of a whole people into another country, by the power of a conqueror.

**TRANSMIGRATION**, is particularly used for the passage of a soul out of one body into another, being the same with what we otherwise call metempsychosis. See **METEMPSYCHOSIS**.

**TRANSMISSION**, in optics, &c. the act of a transparent body passing the rays of light through its substance, or suffering them to pass: in which sense, the word stands opposed to reflection.

Transmission is also frequently used in the same sense with refraction, by which most bodies, in transmitting the rays, do also refract them.

The rays of light, Sir Isaac Newton observes, are subject to fits of easy transmission and reflection. See **LIGHT**.

For the cause of transmission, or the reason why some bodies transmit, and others reflect the rays, see the articles **OPACITY** and **TRANSPARENCY**.

**TRANSMUTATION**, the act of transforming or changing one nature into another.

Nature, Sir Isaac Newton observes, seems delighted with transmutations: he goes on to enumerate several kinds of natural transmutations; gross bodies, and light, he suspects, may be mutually transmuted into each other; and adds, that all bodies receive their active force from the particles of light, which enter their composition. For all fixed bodies, when well heated, emit light as long as they continue so; and again, light intermingles itself, and inheres in bodies, as often as its rays fall on the solid particles of those bodies. Again, water, which is a fluid, volatile, tasteless salt, is by heat, transmuted into a vapour, which is a kind of air; and by cold, into ice, which is a cold transparent brittle stone, easily dissolvable, and this stone is convertible again into water by heat, as vapour is by cold. See **WATER**, **VAPOUR**, **ICE**, &c.

Earth, by heat, becomes fire; and by cold, is converted into earth again: dense bodies, by fermentation, are rarified into various kinds of air; and that air, by fermentation also, and sometimes without, reverts into gross bodies. Quicksilver sometimes puts on the form of a fluid metal, sometimes it appears in shape of a pellucid fragile salt, called sublimate; sometimes of a pellucid, volatile, white, tasteless earth, called mercurius dulcis; by distillation, it becomes vapour; and by agitation in vacuo, it shines like fire, &c. See the articles **EARTH**, **MERCURY**, &c.

All bodies, beasts, fishes, insects, plants, &c. with all their various parts, grow and increase out of water, and aqueous and saline tinctures; and by putrefaction, all of them revert into water or an aqueous liquor again. Farther, water exposed a while to the open air, puts on a tincture, which, in process of time, has a sediment and a spirit, and before putrefaction, yields nourishment both for animals and vegetables.

TRANSMUTATION, in alchemy, denotes the art of changing or exalting imperfect metals into gold or silver.

This is also called the grand operation, and they say, is to be effected with the philosopher's stone. See the article PHILOSOPHER'S STONE.

Some alchemists hold, that the transmutation should rather be called the perfection of imperfect metals; as holding all metals, intended by nature to arrive equally at the perfection of gold, in as much as they are composed of the same matter; and that it is only the impurity of their matrices, that is, in the place wherein they are formed by nature, that has prevented their arriving thereat. The elixir being projected on any of these metals, it is supposed to purge and separate the impure parts from the pure, and to join itself wholly to the mercury (which is the purest part) as being of the same nature.

Whether metals may be transmuted into one another, or not, is a point strongly disputed among philosophers; the alchemists strenuously asserting the affirmative.

TRANSMUTATION, in geometry, denotes the reduction or change of one figure, or body, into another of the same area or solidity, but of a different form; as a triangle into a square, a pyramid into a parallelopiped, &c.

In the higher geometry, transmutation is used for the converting a figure into another of the same kind and order, whose respective parts rise to the same dimensions in an equation, admit of the same tangents, &c.

If a rectilinear figure be transmuted into another, it is sufficient that the intersections of the lines which compose it, be transferred, and the lines drawn through the same in the new figure. If the figure to be transmuted be curvilinear, the points, tangents, and other right-lines, by means whereof the curve line is to be defined, must be transferred.

TRANSOM, among builders, denotes the piece that is framed across a double light window. See WINDOW.

TRANSOM, among mathematicians, signifies the vane of a cross-staff, or a wooden number fixed across, with a square whereon it slides, &c. See CROSS-STAFF.

TRANSOM, in a ship, a piece of timber which lies athwart the stern, between the two fashion-pieces, directly under the gun-room port.

TRANSPARENCY, *Diaphaneity*, in physics, a quality in certain bodies whereby they give passage to the rays of light; in contradistinction to opacity, or that quality of bodies which renders them impervious to the rays of light. See OPACITY.

TRANSPIRATION, the insensible, or almost insensible, passage of an excrementitious matter through the pores of the skin, called also perspiration. See PERSPIRATION.

TRANPIRATION, is also used by some authors for the ingress or entrance of the air, vapour, &c. through the pores of the skin into the body.

Cardan, by this kind of transpiration, accounts for the prodigy of a woman, whose daily urine weighed twenty-seven pounds, though all the food she took, both dry and liquid, did not exceed four pounds.

Dr. Baynard also suspects some such transpiration to be the case in hydropical persons.

TRANSPLANTING, in agriculture and gardening, the act of removing trees or plants from the places where they were sowed, or raised, and planting them in others. See PLANTING.

TRANSPORTATION, the act of conveying or carrying a thing from one place to another.

Transportation is a kind of punishment, or more properly an alleviation or commutation of punishment, for criminals convicted of felony, who, for the first offence (unless it be an extraordinary one) are generally transported to the plantations, there to bear hard labour for a term of years; within which, if they return, they are executed without farther trial.

TRANSPORTATION of Plants, is the sending of plants from one country to another; in performing which, great cautions are necessary.

The plants sent from a hotter country to a colder, should be always put on board in the spring of the year, that the heat of the season may be advancing as they approach the colder climates; and, on the contrary, those which are sent from a colder country to a hotter, should be sent in the beginning of winter.

The best way of packing up plants for a voyage, if they be such as will not bear keeping out of the earth, is to have boxes with handles, filling them with earth, and planting the roots as close together as may be; the plants should be set in these boxes three weeks before they are to be put on board; and in good weather they should be set upon the deck; and in bad, removed or covered with a tarpaulin. If they are going from a hotter country to a colder one, they must have very little moisture; if, on the contrary, they are going from a colder to a warmer, they may be allowed water more largely, and being shaded from the heat of the sun, they will come safe.

A great many plants, however, will live out of the

the earth a considerable while; as the sedums, euphorbiums, ficoides, and other succulent ones. These need no other care than the packing them up with moss in a close box; and there should be a little hay put between them, to prevent their wounding or bruising one another; and holes bored in the boxes, to keep them from heating or putrefying.

In this manner they will come safe from a voyage of two or three, or even four or five months. Several trees also will come safe in the same manner; taking them up at a season when they have done growing, and packing them up with moss. Of this sort, are oranges, olives, capers, jasmynes, and pomegranate-trees. These, and many others, are annually brought over to us from Italy; and, tho' they are three or four months in the passage, seldom miscarry.

The best way of sending over seeds, is in their natural husks, in a bag, or packed up in a gourd-shell, keeping them dry, and out of the way of vermin.

**TRANSPOSITION**, in algebra, the bringing any term of an equation over to the other side. See **EQUATION**.

**TRANSPOSITION**, in grammar, a disturbing or dislocating of the words in a discourse, or a changing of their natural order of construction, to please the ear by rendering the contexture more easy, smooth, and harmonious.

**TRANSPOSITION**, in music, is a changing of the notes of a piece of music, or the shifting a song from its former situation, to set it either higher or lower, or in another octave.

**TRANSUBSTANTIATION**, *Transubstantiatio*, in theology, the conversion or change of the substance of the bread and wine in the eucharist, into the body and blood of Jesus Christ, which the Romish church hold is wrought by the consecration of the priest.

This is a main point in the Romish religion, and is rejected by the Protestants; the former maintaining the transubstantiation to be real, the latter only figurative; interpreting the text, *hoc est corpus meum*, "this signifies my body." But the council of Trent stood up strenuously for the literal sense of the verb *est*, and say expressly, that in transubstantiation the body and blood of our Lord Jesus Christ are truly, really, and substantially, under the species of bread and wine. The controversies about this point, are almost innumerable.

**TRANSUMPTION**, *Transumptio*, in the schools, a syllogism by concession or agreement, used where a question proposed is transferred to another, with this condition, that the proof of this latter should be admitted for the proof of the former. See **SYLLOGISM**.

**TRANSVERSALIS**, in anatomy, a name given to several muscles, &c. in respect of their situation, progress, &c. as, 1. The transversalis abdominis,

a muscle which lies under the obliqui, and arises from the cartilago xiphoidea, from the extremities of the false ribs, from the transverse apophysis of the vertebrae of the loins, is fixed to the inner side of the spine of the ileum, and inserted in the os pubis and linea alba. This, with the obliqui, unites its tendons as it approaches the linea alba, and is the only muscle that is cut in the operation of the bubonocoele. It has a fine and thin membrane, that closes exactly its ring, or hole through which the vessels pass.

2. **Transversalis colli**, is said to be a part of the longissimus dorsi. It arises from the os sacrum, and from all the transverse processes of the vertebrae of the loins, back, and neck, except the two first; and is inserted by so many distinct tendons into all the superior spines. It moves the whole spine obliquely backwards.

3. **Transversalis pedis plantini**, comes from the bone of the metatarsus that sustains the toe next the little toe, and passing across the other bones, is inserted into the os sesamoides of the toe. Its use is to bring all the toes close to one another.

4. **Transversalis penis**, one of the dilators of the urethra, arising from the tubercle of the os ischium on each side, and inserted into the posterior part of the bulb of the urethra; however, these muscles are not quite determinate and certain in their origin or insertion, and sometimes they are wholly wanting: when they act, they dilate the urethra in its posterior part.

5. **Transversalis** is also a name given to a suture of the cranium, because of its traversing or crossing the face from one side to another. See the article **SKULL**.

**TRANSVERSE**, something that goes across another, from corner to corner: thus, bends and bars, in heraldry, are transverse pieces or bearings: the diagonals of a parallelogram, or a square, are transverse lines: lines which make intersections with perpendiculars, are also called oblique or transverse lines.

**TRANSVERSE-MUSCLES**, in anatomy, are certain muscles arising from the transverse processes of the vertebrae of the lines.

**TRAPA**, in botany, a genus of plants, whose flower consists of four oval petals, larger than the cup, with the same number of stamina: there is no pericarpium, but the seed consists of an ovato-oblong nut, armed with four sharp thick spines, placed oppositely in the middle of the sides, and pointed, and contains a single kernel of an oval figure.

**TRAPEZIUM**, in geometry, a plane figure contained under four unequal right lines.

1. Any three sides of a trapezium taken together, are greater than the third.

2. The two diagonals of any trapezium, divide into four proportional triangles.

3. If two sides of a trapezium be parallel, the rectangle

rectangle under the aggregate of the parallel sides and one half their distance is equal to that trapezium.

4. If a parallelogram circumscribes a trapezium, so that one of the sides of the parallelogram be parallel to a diagonal of the trapezium, that parallelogram will be the double of the trapezium.

5. If any trapezium has two of its opposite angles, each a right angle, and a diagonal be drawn joining these angles; and if from the other two angles be drawn two perpendiculars to that diagonal, the distance from the feet of these perpendiculars to those right-angles, respectively taken, will be equal.

6. If the sides of a trapezium be each bisected, and the points of bisection be joined by four right-lines, these lines will form a parallelogram, which will be one half of the trapezium.

7. If the diagonals of a trapezium be bisected, and a right line joins these points, the aggregate of the squares of the sides is equal to the aggregate of the squares of the diagonals, together with four times of the square of the right line joining the point of bisection.

8. In the trapezium, the aggregate of the diagonals is less than the aggregate of four right lines drawn from any point (except the intersection of the diagonals) within the figure.

**TRAPEZIUS**, in anatomy. See the article **CUCULARIS**.

**TRAPEZOID**, is a solid irregular figure, having four sides not parallel to one another.

**TRAVELLERS-Joy**, in botany, the English name for a species of clematitis. See the article **CLEMATITIS**.

**TRAVERSE**, or **TRANSVERSE**, in general, denotes something that goes athwart another; that is, crosses and cuts it obliquely.

Hence, to traverse a piece of ordnance, among gunners, signifies to turn or point it which way one pleases, upon the platform.

In fortification, traverse denotes a trench with a little parapet, or bank of earth, thrown perpendicularly across the moat, or other work, to prevent the enemy's cannon from raking it. These traverses may be from twelve to eighteen feet, in order to be cannon proof, and their height about six or seven feet, or more, if the place be exposed to any eminence. And to preserve a communication, a passage of five or six feet wide must be left at one end of the traverse.

If any part of a work, thus fringed by one or more traverses, is likely to be defended by the musketry, it will be proper to add to the traverses one or more footbanks within the defence, for the troops to mount on, when they want to fire over the traverse.

**TRAVERSE**, in navigation, is a compound

course, wherein several different successive courses and distances are known.

To work a traverse, or to reduce a compound course to a single one, 1. Make a table of six columns, marked course, distance, N. S. E. W. beginning at the left-hand, and write the given courses and distances in their proper columns. 2. Seek the given courses and distances in the traverse table, and let the corresponding differences of latitude and departure be wrote in their proper columns in the table made for the question. 3. Add up the columns of northing, southing, easting, and westing; then the difference between the sums of northing and southing, gives the whole difference of latitude, which is of the same name with the greater; and the difference between the sums of easting and westing will be the whole departure, which is likewise of the same name with the greater. 4. The whole diff. lat. and depart. to the compound course being found, the direct course and distance will be found.

**TRAVERSE**, in law, denotes the denial of some matter of fact alledged to be done in a declaration, or pleadings; upon which the other side coming and maintaining that it was done, issue is joined for the cause to proceed to trial.

**TRAVERSE of an Indictment, or Presentment**, is the contradicting or denying some chief point of it, and taking issue thereon.

**TRAVERSE of an Office**, is the proving that an inquisition made by lands or goods, is defective and untruly made.

**TRAVESTY**, or **TRAVESTI**, a French term, derived from the verb *travestir*, to disguise one's self, or to appear in masquerade: and hence, travesty is applied to the disfiguring of an author, or the translating him into a style and manner different from his own, by which means it becomes difficult to know him.

**TRAUMATICS**, the same with vulnerary medicines. See **VULNERARY**.

**TREACLE**, *Theriaca*, in pharmacy. See the article **THERIACA**.

Some also give the name treacle to melasses; and in this sense it is that Dr. Shaw, in his Essay on distillery, has endeavoured to bring into use several sorts of treacles, which might be made at home, and would serve very conveniently for the distillation of spirits, or the making of potable liquors. These are the inspissated juices or decoctions of vegetables; such as the sweet juice of the birch, or sycamore, procured by tapping or piercing the trees in spring, and the common wort made from malt, or from other vegetable substances treated in the same manner. These liquors are severally to be boiled down in a copper till they begin to inspissate, and then to be poured into a *balneum marie*, when the remainder of the evaporation may be finished

nished without burning the inspissated juices : thus prepared, it may be at any time reduced to the state of wort, only by adding a sufficient quantity of warm water. See TAPPING.

TREASON, in general, signifies betraying ; but is more particularly used for the act or crime of infidelity to one's lawful sovereign.

Treason is divided, by lawyers, into high-treason, and petty-treason. The first of these is an offence committed against the security of the king or kingdom ; as to compass, or imagine, the death of the king, queen, or their eldest son and heir ; or in case a person does violate or deflower the king's wife, or his eldest daughter unmarried, or the wife of the king's eldest son ; or if he levy war against the king within his kingdom, or adhere to his enemies, give them aid or comfort within the realm, or elsewhere ; or if he counterfeit the king's great or privy seal, or his money, or bring false money into the kingdom, like to what we have here, and utter the same : if he kill the chancellor, treasurer, justices of either bench, justices of assize, or of oyer and terminer, sitting in judgment and representing the king's person, in the execution of his office : all these cases are deemed treason by 25 Ed. III. c. 2. which statute is made the only standard of high-treason ; and 1 Mary c. 1. takes away the power of the king and parliament to adjudge any thing else to be high-treason but what is declared to be such therein : it is true, temporary statutes of late times enacted, have made some other offences treason, as relating to papists and the protestant succession.

It has been held, that words only, where they are deliberate, and shew a direct purpose against the king's life, will amount to an overt-act of compassing or imagining his death, and are high-treason : for words are the most natural way of expressing the imagination of the heart, and may be good evidence of it : not only words of persuasion to kill the king, but such as are spoken in order to draw away the affections of his people, and to stir them up against him, are tending to the king's death, and therefore treason. Likewise where a person intends by force to prescribe laws to the king, or to restrain him of his royal power, it has been adjudged an intention to deprive him of his crown and life : and in the eye of the law, every rebellion is a treasonable plot against the life of the king, for a rebel would not suffer that king to live and reign, who would punish his offence.

As to make a crime treason, there must be always some overt-act ; a bare conspiracy, or compassing to levy war, is no such act, unless it be really levied ; in which case the conspirators are all traitors, although they are not in arms : persons that raise forces for any public end or purpose, or who make an insurrection on any account, are said to levy war against the king, though perhaps with-

out a direct design against his person ; and it extends to the case where great numbers forcibly endeavour to remove certain persons from the king, &c. The adhering to the king's enemies, is taken to be an adherence against him, and even out of the realm it is treason : and it is said, that cruising in a ship of war with an intent to destroy the king's ships, though no act of hostility be committed, is an overt-act of adhering, comforting, and aiding.

All trials for high-treason are to be according to the course of the common law ; and persons indicted for this crime, are to have a copy of this indictment five days before their trial, that they may have sufficient time to advise with council ; they shall likewise be permitted to make a full defence by their council learned in the law, and by lawful witnesses, &c. And in this case there must be two evidences to the same overt-act, or to two acts of the same treason, produced face to face against them.

It is also said, where a person is convicted of treason, the omission of any necessary part of the judgment will be held to be error, on which he may reverse the attainder ; as the judgment is severer, and more formidable, in case of high-treason than for any other crime whatever ; since the offender is to be hanged, drawn, and quartered, and also forfeit his lands and goods to the king.

Petty-Treason, is where a servant kills his master, a wife her husband, or a secular or religious person kills his prelate or superior, to whom he owes faith and obedience ; and aiders and abettors, as well as procurers, are within the act. However, so strictly is the statute construed, that no case not expressly mentioned therein is punishable by it : hence if a son kill his father, he shall not be tried for petty treason, except he served his father for wages, in which case he is to be indicted under the name of a servant.

Petty-treason implies the highest degree of murder, and occasions the forfeiture of lands by escheat to the lord of the fee ; and the farther punishment of the criminal is to be hanged, drawn, and quartered for it, and a woman to be burnt.

TREASURE, in general, denotes a store or stock of money in reserve.

Treasure-trove, in law, is where any treasure is found buried in the earth, but not lying on the ground, and no man knows to whom it belongs : this, in England, belongs to the king ; and to conceal it, is punishable by fine and imprisonment.

TREASURER, an officer to whom the treasure of a prince, or corporation, is committed to be kept and duly disposed of.

The lord high treasurer of Great-Britain, or first commissioner of the treasury, when in commission, has under his charge and government all the king's

revenue, which is kept in the exchequer. He holds his place during the king's pleasure, being instituted by the delivery of a white staff to him: he has the check of all the officers employed in collecting the customs and other royal revenues; and in his gift and disposition, are all the offices of the customs in the several ports of the kingdom; escheators in every county are nominated by him; he also makes leases of the lands belonging to the crown.

There is, besides the lord-treasurer, a treasurer of the king's household, who is of the privy-council, and, with the comptroller and steward of the Marshalsea, has great power.

To these may be added the treasurer of the navy; as also the treasurer of the king's chamber, and of the wardrobe; and most corporations throughout the kingdom have treasurers, whose office is to receive their rents, and disburse their common expences.

TREASURY, the place wherein the revenues of a prince are received, preserved, and disbursed.

In England, the Treasury is part of the Exchequer, by some called the Lower Exchequer. See EXCHEQUER.

TREATISE, *Traſſatus*, a set discourse in writing on any subject.

A treatise is supposed more express, formal, and methodical than an essay, but less so than a system. See ESSAY and SYSTEM.

TREATY, a covenant between two or more nations; or the several articles and conditions stipulated and agreed upon between sovereign powers.

Treaties are of various kinds; as treaties of peace, of alliance, of commerce, &c. for the guaranty of which, see the article GUARANTY.

TREBLE, in music, the highest or acutest of the four parts in symphony, or that which is heard the clearest and shrillest in a concert. See the article CLEFF.

TREE, *Arbor*, the first and largest of the vegetable creation, consisting of a single trunk, or stem, from which issueth forth branches, leaves, flowers, and fruit.

There are various kinds of trees; some deciduous, as the elm, lime, &c. others evergreen, as the fir, pine, holly, yew, &c. They are also distinguished, in the nurseries, into dwarfs and standards, particularly fruit-trees. See the articles PLANTING, PRUNING, DWARF, STANDARD, FRUIT-TREES, &c.

TREE-MOSS, *Lichen*, in botany. See the article LICHEN.

TREFOIL, *Trefolium*, in botany, a genus of plants, whose flowers are collected into an umbellated head; they are each papilionaceous, and in some species withering, and others persistent; the vexillum is reflexed, the alæ are shorter than the vexillum, and the carina shorter than the wings:

the fruit is a short unvalvular pod, containing a few roundish seeds. Of this genus the clover is a species. See CLOVER.

Marsh-TREFOIL, *Trifolium Palustre*, in botany, &c. the same with the *menyanthes*, or buckbean. See MENYANTHES.

Shrub-TREFOIL, *Cytisus*, in botany. See the article CYTISUS.

TREMELLA, in botany, a genus of cryptogamous plants, of the flag-kind; they consist of an uniform substance, which is foliaceous, pellucid, and membranaceous, and in some respects like the lichen. See LICHEN.

TREMBLING of the Joints, or TREMOR, is an involuntary shaking, chiefly of the hands and head, sometimes of the feet, and sometimes of the tongue and heart.

It is a disorder which frequently attacks persons advanced in years, and sometimes the younger sort. It seems to arise from a defect of spirits, sometimes from terror, or other violent passion, and sometimes from a plethora. Too much drinking of coffee also produces a tremor in some persons, as too plentiful drinking and surfeits will in others.

Tremors are often dangerous, as being apt to degenerate into other nervous distempers; as spasms, the palsy, lethargy, apoplexy, &c.

In the cure, those things should be avoided that promote the disease, and the patient should drink balm or sage tea, or a diet-drink made of china-root; peruvian bark may also be taken, in an infusion of balm or sage, or succinated spirit of hart's-horn, twice or thrice in a day; and in the evening an antispasmodic powder may be taken, especially if the patient is hot, or uses much wine.

Outwardly, the neck and spine of the back may be rubbed with the spirits of ants, earth-worms, and sal ammoniac, mixed together; a fourth part of the volatile spirits will be sufficient, or opodeldoc may be used in their stead. If the patient is plethoric, bleeding is useful; and in old persons, a draught of generous wine at meals: pediluvia, hot-baths, and mineral waters, may be also used, but with caution.

As to the medicine commonly used in tremors and other nervous distempers, under the name of palsy-drops, it is no other than compound spirit of lavender; the most successful way of using which is, by taking thirty or forty drops twice or thrice a day, dropped on loaf-sugar, or a little bread. It is supposed, that by this way, the most spirituous and efficacious parts make their way directly by the nerves of the palate, &c. without undergoing the course of the circulation, as it is said to do when taken in a liquid vehicle.

TRENCHES, in fortification, are ditches cut by the besiegers, that they may approach more securely to the place attacked; whence they are also called

lines of approach. The tail of the trench is the place where it was begun, and its head is the place where it ends.

The trenches are usually opened, or begun, in the night time; sometimes within musket shot, and sometimes within half or whole cannon-shot of the place. They are carried on in winding lines, nearly parallel to the works of the fortrefs, so as not to be in the view of the enemy, nor exposed to the enemy's shot.

The workmen employed in the trenches are always supported by a number of troops, to defend them against the sallies of the besieged: the pioneers sometimes work on their knees, and are usually covered with mantlets or fauciflons; and the men who support them lie flat on their faces, in order to avoid the enemy's shot.

TRENTAL, or TRIGINTAL, a Romish office for the dead, consisting of thirty masses rehearsed for thirty days successively after the party's death. See MASS.

TREPAN, *Terebra*, *Modiolus*, &c. in surgery, an instrument used in trepanning. See the next article.

TREPANNING, in surgery, a perforation, or opening, made in the bones of the cranium, or skull. See the article CRANIUM.

This operation was performed by the ancients, not only in fractures and depressions of the cranium, but also in those other obstinate disorders of the head and brain, which could not be relieved by internal medicines, and the use of issues upon the coronal future; but the modern surgeons never use the trepan for internal disorders of the head, though they seldom neglect it in fractures and depressions of the cranium.

The trepan is therefore useful, not only in these cases, to elevate the depressed parts of a fractured bone in the cranium, but also to discharge the extravasated blood through an aperture made by this instrument. See the articles CONTRA-FISSURE, CONTUSION, EXTRAVASION, &c.

The less time there is lost, the better, before the application of the trepan, but the operation itself must be conducted slowly and carefully; for it is extremely difficult, if not impossible, to take out a piece of the cranium by this instrument, without injuring the subjacent dura mater, to which it is most intimately attached. See DURA MATER.

For this reason, Heister is induced to condemn the advice of those who direct to trepan the cranium immediately upon every slight disorder of it: he therefore advises, first, to try the use of other remedies, both external and internal, rather than immediately subject the patient to the trepan, before it is absolutely necessary.

In general, the place where the fissure appears will be the most convenient to apply the trepan, if nothing indicates the contrary; but in fractures, it

will be proper to trepan a little below the injured part, that the extravasated blood may be more easily discharged.

After having pitched upon the part to be trepanned, the next business is to shave the scalp, and make an incision through the integuments to lay bare the cranium, except it be done already by the wound. The incisions of the integuments may be made in the form of a cross, large enough to admit the crown of the trepan upon the bone.

TREPIDATION, in medicine, the same with tremor. See TREMBLING.

TREPIDATION, in the ancient astronomy, denotes what they call a libration of the eighth sphere, or a motion which the Ptolemaic system attributed to the firmament, to account for certain and almost insensible changes and motions observed in the axis of the world, by means whereof the latitudes of the fixed stars come to be gradually changed, and the ecliptic seems to approach reciprocally first towards one pole, then towards the other.

This motion is called the motion of the first libration. See the articles LIBRATION and TUBATION.

TRESPASS, in law, signifies any transgression of the law, under treason, felony, or misprision of either; but it is most commonly used for any wrong or damage that is done by one private person to another, or to the king in his forest, &c.

In this sense, trespass is of two sorts: trespass general, which is called trespass *vi et armis*; and trespass special, or trespass upon the case. Trespasses against a man's person are such as these, viz. threatening to hurt him, on assaulting or setting one to beat him; a battery, which is an actual beating or maiming a man so that he lose the use of his limbs; an unlawful imprisonment of another, or illegally restraining him of his liberty.

Trespasses committed against a man's property may be in several ways, as against his wife, children, or servants, or his house and goods, &c. or against his lands, by carrying away the deeds, or other evidences, concerning the same; cutting trees or damaging the grass therein. An action of trespass, *vi et armis*, lies for a person who has the possession of goods, or of a house, or land, if he be disturbed in his possession, for this reason, that such disturbance, besides the private damage, is also a breach of the peace; and in case the defendant be convicted at common law, he is liable to be fined and imprisoned. The difference between this action and trespass on the case is, that the one lies where the original act was a wrong in itself, and the other where it is consequential to a lawful act. A defendant in trespass shall in no case be excused, unless it be upon an unavoidable necessity; therefore, where there is only a force in law, as if a person enters into another's land, he must be requested to go out before hands are laid on him, but

but it is otherwise when there is an actual force committed.

The defendant in trespass can, by his plea, put the plaintiff to a new assignment of the place where, &c.

**TRESSURE**, in heraldry, a diminutive of an orle, usually held to be half the breadth thereof.

**TRET**, in commerce, an allowance made for the waste, or the dirt, that may be mixed with any commodity, which is always four pounds in every one hundred and four pounds weight.

**TREWIA**, in botany, a genus of plants, whose flower is apetalous; the cup contains a great number of stamina, and the fruit is a turbinated, three-cornered, coronated capsule, having three valves and three cells, each containing a single seed, convex on one side and angular on the other.

**TRIAL**, in law, the examination of a cause, civil or criminal, according to the laws of the land, before a proper judge: or, it is the matter and order observed in the hearing and determining of causes.

There are divers kinds of trials; as those of matters of fact, which must be tried by a jury; matters of law, which are only triable by the courts; and matters of record, which are to be tried by the records themselves.

**TRIANDRIA**, in botany, the name of the third class in the Linnæan system, consisting of those plants which bear hermaphrodite flowers, each containing three stamina, or male parts.

To this class belong the reed, barley, wheat, &c. with most of the grass tribe.

**TRIANGLE**, in geometry, a figure of three angles.

Triangles are either plane or spherical. A plane triangle is contained under three right lines; and a spherical one is a triangle contained under three arches of great circles of the sphere. See the article **SPHERE**.

Triangles are denominated, from their angles, right, obtuse, and acute.

A right-angled triangle is that which has one right angle, as  $ABC$ , (plate LXXXIII. fig. 1.)

An obtuse-angled triangle is such as has one obtuse angle; as  $DEF$ ; (fig. 2.)

And an acute-angled triangle is that which has all its angles acute; as  $ghi$ ,  $GHI$ , (fig. 3 and 4.) See the article **ANGLE**.

And here it may not be improper to explain other distinctions of triangles.

Any triangle that is not right-angled, is called oblique-angled, or amblygonial.

An equilateral-triangle is that which has all its sides equal; as  $ghi$ , (fig. 3.)

An isosceles-triangle is one that has only two sides equal; as  $GHI$ , (fig. 4.)

And a scalenous-triangle is one that has no two sides equal; as  $DEF$ , (fig. 2.)

In every triangle the sines of the sides are proportional to the sines of the opposite angles; also the sine of all the three angles is equal to two right ones; and the external angle, made by any side produced, is equal to the sum of the two internal and opposite angles: thus  $\angle eED$ , (fig. 2.)  $= \angle EFD + FDE$ .

Triangles on the same base, and having the same height or place, between the same parallels, are equal: also triangles on equal bases, and between the same parallels, are equal. If a perpendicular be let fall upon the base of an oblique-angled triangle, the difference of the squares of the sides is equal to the double rectangle under the base, and the distance of the perpendicular from the middle of the base. The side of an equilateral triangle, inscribed in a circle, is in power triple of the radius. The sides of a triangle are cut proportionably, by a line drawn parallel to its base. A whole triangle is to a triangle cut off by a right line drawn parallel to the base, as the rectangle under the cut sides is to the rectangle of the two other sides. In a right-angled triangle, a line drawn from the right-angle at the top, perpendicular to the hypotenuse, divides the triangle into two other right-angled triangles, which are similar to the first triangle, and to one another. In every right-angled triangle, the square of the hypotenuse is equal to the sum of the squares of the other two sides; that is,  $AC^2$  (fig. 1.)  $= AB^2 + BC^2$ . If any angle of a triangle be bisected, the bisecting-line will divide the opposite side in the same proportion as the legs of the angle are to one another. Every triangle is one half of a parallelogram of the same base and height.

The area of any triangle may be had by adding all the three sides together, and taking half the sum, and from that half sum subtracting each side severally, and multiplying that half sum and the remainder continually into one another, and extracting the square root of the product.

For the solving the several cases of plane and spherical triangles, see the article **TRIGONOMETRY**.

**TRIANGULAR Compasses**, are such as have three legs, or feet, whereby to take off any triangle at once; much used in the construction of maps, globes, &c.

**TRIANGULAR Numbers**, are a kind of polygonal numbers, being the sums of arithmetical progressions, the difference of whose terms is 1.

Thus of arithmetical progression, 123456, are formed triangular numbers 136101521.

**TRIANGULAR Canon**, the tables of artificial sines, tangents, secants, &c.

**TRIANGULAR Quadrant**, is a sector furnished with a loose piece, whereby to make an equilateral triangle.

The calendar is graduated thereon, with the sun's place, declination, and other useful lines; and by the

the help of a string and a plummet, and the divisions graduated on the loose piece, it may be made to serve for a quadrant.

**TRIANGULARIS**, in anatomy, a name given to two muscles of the lips, which arise each from the lateral and under part of the lower jaw; from whence they ascend obliquely to the angle of the orbicularis.

There is also a muscle of the breast called *triangularis sterni*, which rises from the lower and interior part of the sternum, and is inserted on each side into the cartilages of the fourth, fifth, sixth, and seventh true ribs: it is one of the constrictor or depressor muscles of the breast.

One of the dilator muscles of the urethra is also called *triangularis*, from its figure: it rises from the anterior part of the sphincter of the anus, and is inserted into the posterior and lower parts of the accelerators, or else into the bulb of the urethra.

**TRIANTHEMA**, in botany, a genus of plants, whose flower consists of oval, equal, and patent petals, with ten filaments, topped with oval twin antheræ; the fruit is a cylindric unilocular capsule, a little compressed, and contains ten rough kidney-shaped seeds.

**TRIBULUS**, caltrop, in botany, a genus of plants, whose flower consists of five oblong, obtuse, and patent petals, with ten small subulated stamina; the fruit is roundish and aculeated, being composed of five capsules, gibbous on one side, and armed with three or four points on the other, and joined together, each containing a few oblong turbinated seeds.

**TRIBUNAL**, in general, denotes the seat of a judge, called in our courts, bench.

The word is Latin, and takes its origin from the seat where the tribune of the Roman people was placed to administer justice.

The name tribunal was also given to the place from whence the people of ancient Rome were harangued.

**TRIBUNE**, *Tribunus Plebis*, among the ancient Romans, a magistrate chosen out of the commons, to protect them against the oppressions of the great, and to defend the liberty of the people against the attempts of the senate and consuls.

**TRIBUTARY**, *Tributarius*, one who pays tribute to another, in order to live in peace with him, or share in his protection.

**TRIBUTE**, *Tributum*, a tax or impost which one prince or state is obliged to pay to another as a token of dependence, or in virtue of a treaty, and as a purchase of peace.

**TRICEPS**, in anatomy, the abductor muscle of the thigh, having three heads, and as many insertions: the first and second heads of this muscle arise from the os pubis, near the synchondrosis; the third, from the tubercle of the ischium; and it is inserted into the whole spine of the os femoris.

**TRICHIASIS**, in surgery, an inversion of the eye-lids, whereby the eye-lashes hurt the eyes.

**TRICHILIA**, in botany, a genus of plants, whose flower consists of five lanceolated patent petals, with a cylindric tubulose nectarium, cut at the mouth into five indentures; the stamina have no filaments, but consist of ten erect assurgent antheræ; the fruit is a roundish almost trigonal capsule, having three cells, each containing a single seed.

**TRICHOMANES**, in botany, a genus of cryptogamous plants, of the fern kind; the visible parts of the fructification consists of a turbinated erect calyx standing singly on the very margin of the leaf, and a setaceous style terminating the capsule.

**TRICHOSANTHES**, in botany, a genus of plants, whose flowers are male and female, and grow on the same plant; the male flower is monopetalous, and divided into five segments, and contains three very short filaments, topped with cylindrical erect antheræ joined in a body; the female flower is like the male, and the fruit is long, succulent, and trilocular, containing many obtuse compressed seeds. This genus comprehends the *anguina* of Micheli.

**TRICHOSTEMA**, in botany, a genus of plants, whose flower is monopetalous and ringent; the tube is very short, the upper-lip is compressed and falcated, and the under one is divided into three parts, the middle one being oblong and smallest; the stamina are four very long filaments, topped with single antheræ; there is no pericarpium, but the cup contains four roundish seeds.

**TRICUSPIDES VALVÆ**, in anatomy, a name given to the mitral valves, placed at the juncture of the right auricle and ventricle of the heart.

**TRIDAX**, American starwort, in botany, a genus of plants, whose flowers is compound and radiated, consisting of hermaphrodite florets, which form the disc, and ligulated female corollulæ, which compose the rays; the cup, which is cylindrical and imbricated, contains the seeds, which are oblong and crowned with down.

**TRIDENT**, *Tridens*, an attribute of Neptune, being a kind of sceptre which the painters and poets put into the hands of that god, in form of a spear, or fork, with three teeth: whence the word.

**TRIDENT**, among mathematicians, is used for a kind of parabola, by which Des Cartes constructed equations of six dimensions.

**TRIEDROSTYLA**, in natural history, the name of a genus of spars, in form of trigonal columns, adhering by one end to some solid body, and terminated at the other by a trigonal pyramid. See *SPAR*.

**TRIEMIMERIS**, a kind of cæsura in Latin verse, wherein after the first foot of the verse there remains an odd syllable, which helps to make up the next foot.

Fig. 1. Triangles.

Fig. 2. Rectangular Trigonometry.

Fig. 4. Spherical Trigonometry.

Fig. 3. Oblique-angled Trigonometry.

**TRIENNIAL**, an epithet applied chiefly to offices or employments which last for three years.

**TRIENS**, in antiquity, a copper money of the value of one third of an as, which on one side bore a Janus's head, and on the other a water-rat.

**TRIENTATIS**, in botany, a genus of plants, whose flower is stellated and monopetalous, with the corolla divided into seven ovato-lanceolated segments; the stamina consists of seven capillary filaments, inserted into the unguis of the corolla, and topped with single antheræ.

**TRIFOLIUM**, trefoil, in botany. See the article **TREFOIL**.

**TRIGA**, in antiquity, denotes a kind of carr, or chariot, drawn by three horses; whence the name.

**TRIGAMY**, a third marriage, or the state of a person who has been married three times. See **MARRIAGE**.

**TRIGLOCHIN**, in botany, a genus of plants, whose flower consists of three oval-concave obtuse petals, with six very short filaments, and the same number of antheræ; the fruit is an oblong capsule, with three cells, each inclosing an oblong seed.

**TRIGLYPTHS**, in architecture, a sort of ornaments repeated at equal intervals in the Doric frieze.

Each triglyph consists of two entire gutters, or channels, cut to a right angle, called glyphes, and separated by three interstices, called, by Vitruvius, femora, from each other, as well as from two other half channels which are at the sides.

**TRIGON**, *τρίγωνος*, a triangle. See the article **TRIANGLE**.

**TRIGONELLA**, *foenugreek*, in botany. See **FOENOGREEK**.

**TRIGONOMETRY**, that part of geometry which teaches how to measure the sides and angles of triangles. See **TRIANGLE**.

Trigonometry is either plane or spherical, according as the triangles are plane or spherical; of each whereof we shall treat in order.

**Plane TRIGONOMETRY**, or that which teaches the mensuration of plane triangles, is commonly divided into rectangular and oblique-angular.

I. And first of rectangular plane trigonometry; if in any right-angled triangle  $ABC$  (plate **LXXXVIII.** fig. 2.  $N^o$  1.) the hypotenuse be made the radius, and with that a circle be described on the one end,  $A$ , as a center; then, it is plain, that  $BC$  will be the sine of the angle  $BAC$ ; and if, with the same distance, and on the end  $B$  as a center, a circle be described, it is plain that  $AC$  will be the sine of the angle  $ABC$ ; therefore, in general, if the hypotenuse of a right-angled triangle be made the radius, the two legs will be the sines of their opposite angles. See the articles **SINE**, **RADIUS**, &c.

Again, if in a right-angled triangle  $DEF$  ( $N^o$  2.) one of the legs, as  $DF$ , be made the radius, and on the extremity  $D$  (at one of the oblique angles, viz. that which is formed by the hypotenuse and the leg made radius) as a center, a circle be described; it is plain that the other leg,  $EF$ , will be the tangent of the angle at  $D$ , and the hypotenuse  $DE$  will be the secant of the same angle. The same way, making the leg  $EF$  the radius, and on the center  $E$  describing a circle, the other leg  $DF$  will become the tangent of the angle at  $E$ , and the hypotenuse  $DE$  the secant of the same. See **TANGENT** and **SECANT**.

The chord, sine, tangent, &c. of any arch, or angle, in one circle, is proportionable to the chord, sine, tangent, &c. of the same arch in any other circle: from which, and what has been said above, the solutions of the several cases of rectangular trigonometry naturally follow. See **CHORD**, **ARCH**, &c.

Since trigonometry consists in determining angles and sides from others given, there arises various cases; which being seven in rectangular-trigonometry, are as follow:

Case I. The angles, and one of the legs, of a right-angled triangle be given, to find the other leg. Example: in the triangle  $ABC$  ( $N^o$  3.) right-angled at  $B$ , suppose the leg  $AB=86$  equal parts; as feet, yards, miles, &c. and the angle  $A=33^{\circ} 40'$ ; required the other leg  $BC$ , in the same parts with  $AB$ .

1. Geometrically: Draw  $AB=86$ , from any line of equal parts; upon the point  $B$ , erect the perpendicular  $BC$ ; and, lastly, from the point  $A$ , draw the line  $AC$ , making with  $AB$  an angle of  $33^{\circ} 40'$ ; and that line produced will meet  $BC$  in  $C$ , and so constitute the triangle. The length of  $BC$  may be found by taking it in your compasses, and applying it to the same line of equal parts that  $AB$  was taken from.

2. By calculation: First, by making the hypotenuse  $AC$  radius, the other two legs will be the sines of their opposite angles, viz.  $AB$  the sine of  $C$ , and  $CB$  the sine of  $A$ .

Now, since the sine, tangent, &c. of any arch in one circle, is proportionable to the sine, tangent, &c. of the same arch in any other circle, it is plain the sines of the angles  $A$  and  $C$ , in the circle described by the radius  $AC$ , must be proportional to the sine of the same arches or angles, in the circle, that the table of artificial sines, &c. was calculated for; so the proportion for finding  $BC$  will be

$$S, C : A B :: S, A : B C$$

i.e. As the sine of the angle  $C$  in the tables, is to the length of  $AB$  (or sine of  $C$  in the circle whose radius is  $AC$ ) so is the sine of the angle  $A$  in the tables, to the length of  $BC$  (or sine of the same angle in the circle whose radius is  $AC$ .)

Now, the angle A being  $33^{\circ} 40'$ , the angle C must be  $56^{\circ} 20'$ ; therefore, looking in the table of artificial sines, &c. for the sines of the two angles, and in the table of logarithms for the logarithm of 86 the given leg, we shall find by proceeding according to the foregoing proportion, that the required leg BC, is 57.28; and the operation will stand as follows:

$$\begin{array}{r} 1.93450 \quad AB \quad 86 \\ 9.74380 \quad S, A \quad 33^{\circ} 40' \end{array}$$

$$\begin{array}{r} 11.67830 \\ 9.92027 \quad S, C \quad 56^{\circ} 20' \end{array}$$

$$1.75803 \quad BC \quad 57.28$$

Secondly, making AB the radius, it is plain BC, the leg required, will be the tangent of the given angle A, and so the proportion for finding BC, when AB is made the radius, will be:

$$R : T, A :: AB : BC$$

i. e. as the radius of the tables, is to the tangent of the angle A in the same, so the length of BA, or radius in the scheme, to the length of BC or tangent of A in the scheme; therefore, looking in the tables for the parts given in the foregoing proportion, and proceeding with them according to that rule, we shall find BC to be 57.28, as before, and the operation will be as follows:

$$\begin{array}{r} 9.82352 \quad T, A \quad 33^{\circ} 40' \\ 1.93450 \quad AB \quad 86 \end{array}$$

$$\begin{array}{r} 11.75802 \\ 10.00000 \quad Rad. \quad 90^{\circ} \end{array}$$

$$1.75802 \quad BC \quad 57.28$$

Lastly, by making BC, the leg required, the radius, it is plain that AB will be the tangent of C, and the proportion for finding BC will be as follows:

$$T, C : R :: AB : BC$$

$$\begin{array}{r} i. e. \text{ as the tangent of } C \quad 56^{\circ} 20' \quad 10.17648 \\ \text{is to radius} \quad \quad \quad 90^{\circ} \quad 10.00000 \\ \text{so is the length of } AB \quad 86 \quad 1.93450 \end{array}$$

$$\begin{array}{r} 11.93450 \\ 10.17648 \end{array}$$

$$\text{to the length of } BC \quad 57.28 \quad 1.75802$$

Case II. The angles and one of the legs given, to find the hypoth. Example: in the triangle ABC ( $N^{\circ} 4.$ ) suppose AB 124, and the angle A  $34^{\circ} 28'$ ; consequently the angle C  $53^{\circ} 40'$ , required the hypotenuse AC, in the same parts with AB.

1. Geometrically: this case is constructed after the same manner with the former; and the hypotenuse, AC, is found, by taking its length in your compasses, and applying that to the same line of equal parts from which AB was taken.

2. By calculation: first, making AC the radius, we shall have the following proportion for finding AC, viz.

$$S, C : R :: AB : AC.$$

$$\begin{array}{r} i. e. \text{ as the sine of } C \quad 55^{\circ} 40' \quad 9.91686 \\ \text{is to radius} \quad \quad \quad 90^{\circ} \quad 10.00000 \\ \text{so is } AB \quad \quad \quad 124 \quad 2.09342 \\ \text{to } AC \quad \quad \quad 150.2 \quad 2.17656 \end{array}$$

Secondly, making AB the radius, we have this proportion, viz.

$$R : \sec. A :: AB : AC.$$

$$\begin{array}{r} i. e. \text{ as the radius} \quad 90^{\circ} \quad 10.00000 \\ \text{to the secant of } A \quad 34^{\circ} 20' \quad 10.08314 \\ \text{so is } AB \quad \quad \quad 124 \quad 2.09342 \\ \text{to } AC \quad \quad \quad 150.2 \quad 2.17656 \end{array}$$

This may also be done without the help of the secants; for since  $R : \sec. :: Co-S. : R$ ; therefore, the former proportion will become,

$$Co-S. A : R :: AB : AC.$$

$$\begin{array}{r} i. e. \text{ as the co-sine of } A \quad 34^{\circ} 20' \quad 9.91686 \\ \text{is to the radius} \quad \quad \quad 90^{\circ} \quad 10.00000 \\ \text{so is } AB \quad \quad \quad 124 \quad 2.09342 \\ \text{to } AC \quad \quad \quad 150.2 \quad 2.17656 \end{array}$$

Thirdly, making BC the radius, we have the following proportion, viz.

$$T, C : \sec. C :: AB : AC.$$

$$\begin{array}{r} i. e. \text{ as the tangent of } C \quad 55^{\circ} 40' \quad 10.16558 \\ \text{is to sec. } C \quad \quad \quad 55^{\circ} 40' \quad 10.24872 \\ \text{so is } AB \quad \quad \quad 124 \quad 2.09342 \\ \text{to } AC \quad \quad \quad 150.2 \quad 2.17656 \end{array}$$

This likewise may be done without the help of secants; for since  $T, \sec. :: S. : R$ ; therefore, the former analogy will be reduced to this, viz.

$$S, C : R :: AB : AC$$

where no secants do appear, and it coincides with that of the first supposition of this case, so we shall not repeat the operation.

Case III. The angles and hypotenuse given, to find either of the legs. Example: in the triangle ABC ( $N^{\circ} 4.$ ) suppose the hypotenuse AC=146, and the angle A= $36^{\circ} 25'$ ; consequently the angle C= $53^{\circ} 35'$ ; required the leg AB.

1. Geometrically: draw the line AB at pleasure, and make the angle BAC equal to  $36^{\circ} 25'$ ; then take AC equal to 146 from any line equal parts; lastly, from the point C, let fall the perpendicular CB, on the line AB. So the triangle is constructed, and AB may be measured from the line of equal parts.

2. By calculation: first, making AC the radius, we shall have the following proportion, viz.

$$R : S, C :: AC : AB.$$

$$\begin{array}{r} i. e. \text{ as radius} \quad \quad \quad 90^{\circ} \quad 10.00000 \\ \text{to the sine of } C \quad \quad \quad 53^{\circ} 35' \quad 9.90565 \\ \text{so is } AC \quad \quad \quad 146 \quad 2.16435 \\ \text{to } AB \quad \quad \quad 117.5 \quad 2.07000 \end{array}$$

Secondly, making AB the radius, we have the following analogy, viz.

# TRI

Sec. A: R::AC:AB.

|                          |         |          |
|--------------------------|---------|----------|
| i. e. as the secant of A | 36° 25' | 10.09435 |
| is to radius             | — 90°   | 10.00000 |
| so is AC                 | — 146   | 2.16435  |
| to AB                    | — 117.5 | 2.07000  |

This may also be done without the help of secants; for since sec.:R::R Co-S, the former proportion may be reduced to this, viz.

R:Co-S.A::AC:AB

which is the same with the proportion in the first supposition.

Thirdly, by supposing BC the radius, we have the following proportion, viz.

Sec. C:T,C::AC:AB.

|                          |         |          |
|--------------------------|---------|----------|
| i. e. as the secant of C | 53° 35' | 10.22647 |
| is to the tangent of C   | 53° 35' | 10.13212 |
| so is AC                 | — 146   | 2.16435  |
| to AB                    | — 117.5 | 2.07000  |

Case IV. The two legs being given, to find the angles. Example: in the triangle ABC (N° 5.) suppose AB 94, and BC 56; required the angles A and C.

1. Geometrically: draw AB equal to 94, from any line of equal parts, then from the point B raise BC perpendicular to AB, and take BC, from the former line of equal parts equal to 56; lastly, join the parts A and C with the straight line AC, so the triangle is constructed, and the angles may be measured by a line of chords. See the articles SCALE and SECTOR.

2. By calculation: first, supposing AB the radius, we have this analogy, viz.

AB:BC::R:T, A.

|                     |         |          |
|---------------------|---------|----------|
| i. e. as AB         | 94      | 1.97313  |
| is to BC            | 56      | 1.74819  |
| so is the radius    | 90°     | 10.00000 |
| to the tangent of A | 30° 47' | 9.77506  |

Secondly, making BC the radius, we have this proportion, viz.

BC:BA::R:T, C.

|                     |         |          |
|---------------------|---------|----------|
| i. e. as BC         | 56      | 1.74819  |
| is to AB            | 94      | 1.97313  |
| so is the radius    | 90°     | 10.00000 |
| to the tangent of C | 59° 13' | 10.22494 |

Case V. The hypotenuse and one of the legs given, to find the angle.

Example: in the triangle DEF, (N° 6.) suppose the leg DE=83, and the hypotenuse DF=126; required the angles D and F.

1. Geometrically: draw the line DE=83, from any line of equal parts; and, from the point E, raise the perpendicular EF: then take the length of DF=126, from the same line of equal parts; and setting one foot of your compasses in D, with the other cross the perpendicular EF in E; lastly, join D and F; and the triangle being thus constructed, the angles may be measured by a line of chords.

# TRI

2. By calculation: first, making DF the radius, we shall have this proportion, viz.

DF:DE::R:S, F.

|                  |         |          |
|------------------|---------|----------|
| i. e. as DF      | 126     | 2.10037  |
| is to DE         | 83      | 1.91908  |
| so is the radius | 90°     | 10.00000 |
| to the sine of F | 41° 12' | 9.81871  |

Secondly, by supposing DE the radius, we have the following analogy, viz.

DE:DF::R:Sec. D.

|                    |         |          |
|--------------------|---------|----------|
| i. e. as DE        | 83      | 1.91908  |
| is to DF           | 126     | 2.10037  |
| so is radius       | 90°     | 10.00000 |
| to the secant of D | 48° 48' | 10.18129 |

This may be done without the help of secants; for since R: sec.:Co-S, :R, the foregoing analogy will become this, viz.

DF:DE::R:Co-S, D.

which gives the same answer, with that deduced from the first supposition.

Case VI. The two legs being given, to find the hypotenuse.

Example: In the triangle ABD, (N° 7.) suppose the leg AB=64, and BD=56: required the hypotenuse,

1. Geometrically: the construction of this case is performed the same way as in the fourth case, and the length of the hypotenuse is found by taking it in your compasses, and applying it to the same line of equal parts, that the two legs were taken from.

2. By calculation: this case being a compound of the fourth and second cases, we must first find the angles by the fourth, thus:

AB:DB::R:T, A.

|                     |         |          |
|---------------------|---------|----------|
| i. e. as the leg AB | 64      | 1.80618  |
| is to the leg DB    | 56      | 1.74819  |
| so is the radius    | 90°     | 10.00000 |
| to the tangent of A | 41° 11' | 9.94201  |

Then by the second case we find the hypotenuse required thus:

S, A:R::BD:AD,

|                     |         |          |
|---------------------|---------|----------|
| i. e. as the sine A | 41° 12' | 9.81854  |
| is to the radius    | 90°     | 10.00000 |
| so is the leg BD    | 56      | 1.74819  |
| to the hypoth. AD   | 85.05   | 1.92955  |

This case may also be solved after the following manner, viz.

From twice the log. of the greater side AB 3.61236 subtract the log. of the lesser side BD — 1.74819

and there remains — — — 1.86417

the logarithm of 73.15; to which adding

the lesser side BD, we shall have — 189.15

whose log. is — — — 2.11093

to which add the log. of the lesser side BD 1.74819

and the sum will be — — — 3.85912

the half of which is — — — 1.92956  
the

# TRI

the logarithm of the hypotenuse required. See LOGARITHM.

Or it may be done by adding the square of the sides together, and taking the logarithm of that sum, the half of which is the logarithm of the hypotenuse required: thus, in the present case, the square of A B (64) is — — — 4096  
the square of B D (56) is — — — 3136

the sum of these squares is — — — 7232  
the log. of which is — — — 3.85926  
the half of which is — — — 1.92963  
= to the logarithm of 85.05, the length of the hypotenuse required.

Case VII. The hypotenuse and one of the legs being given, to find the other leg.

Example: in the triangle BGD, (N<sup>o</sup> 8.) suppose the leg BG = 87, and the hypotenuse BD = 142; required the leg DG.

1. Geometrically: the construction here is the same as in case V. the same things being given; and the leg DG is found by taking its length in your compasses, and applying that to the same line of equal parts the others were taken from.

2. By calculation: the solution of this case depends upon the 1<sup>st</sup> and 5<sup>th</sup>; and first we must find the oblique angles by case 5<sup>th</sup>, thus:

$$DB:BG::R:S, D.$$

i. e. as the hypoth. DB 142 2.15229  
is to the leg BG 87 1.93952  
so is radius 90° 10.00000  
to the sine of D 37° 47' 9.78723

Then by case 1<sup>st</sup>, we find the leg DG required, thus:

$$R:S, B::BD:DG,$$

i. e. as radius 90° 10.00000  
is to the sine of B 52° 13' 9.89781  
so is the hypoth. DB 142 2.15229  
to the leg DG 112.2 2.05010

The leg DG may be found in the following manner, viz.

To the log. of the sum of the hypotenuse and given leg, viz. 229 } 2.35984  
add the log. of their difference, viz. 55 } 1.74036

and their sum is — — — 4.10020  
the half of that is — — — 2.05010  
the log. of 112.2, the leg required.

Or it may be done by taking the square of the given leg from the square of the hypotenuse, and the square root of the remainder is the leg required: thus, in the present case.

The square of the hypotenuse (142) is 20164  
The square of the leg BG (87) is 7569

Their difference is — — — 12595  
Whose logarithm is — — — 4.10020  
The half of which is — — — 2.05010

which answers to the natural number 112.2, the leg required.

# TRI

Thus have we gone through the seven cases of right-angled plane-trigonometry; from which we may observe; 1. That to find a side, when the angles are given, any side may be made the radius. 2. To find an angle, one of the given sides must of necessity be made the radius.

II. We now proceed to oblique angled plane-trigonometry, in which there are six cases: but before we shew their solution, it will be proper to premise the following theorems.

Theorem 1. In any triangle ABC (fig. 3. N<sup>o</sup> 1.) the sides are proportional to the sines of the opposite angles: thus, in the triangle ABC, AB:BC::S, C:S, A, and AB:AC::S, C:S, B: also AC:BC::S, B:S, A.

Demonstration: let the triangle ABC be inscribed in a circle; then, it is plain (from the property of the circle) that the half of each side is the sine of its opposite angle: but the sines of these angles in tabular parts, are proportioned to the sines of the same in any other measure; therefore, in the triangle ABC, the sines of the angles will be as the halves of their opposite sides; and since the halves are as the wholes, it follows, that the sines of the angles are as their opposite sides; i. e. S, C:S, A::AB:BC, &c.

Theor. 2. In any plane triangle, as ABC (N<sup>o</sup> 2.) the sum of the sides, A B and B C, is to the difference of these sides, as the tangent of half the sum of the angles BAC, ABC, at the base, is to the tangent of half the difference of these angles.

Demonst. Produce AB; and make BH equal to BC; join HC, and from B let fall the perpendicular BE; through B draw BD parallel to AC, and make HF equal to CD, and join BF; also make BI equal to BA, and draw IG parallel to BD or AC.

Then it is plain that AH will be the sum, and HI the difference of the sides A B and B C; and since HB is equal to BC, and BE perpendicular to HC, therefore HE is equal to EC; and BD being parallel to AC and IG, and AB equal to BI, therefore CD or HF is equal to GD, and consequently HG is equal to FD, and half HG is equal to half FD or ED. Again, since HB is equal to BC, and BE perpendicular to HC, therefore the angle EBC is half the angle HBC; but the angle HBC is equal to the sum of the angles A and C, consequently the angle EBC is equal to half the sum of the angles A and C. Also since HB is equal to BC, and HF equal to CD, and the included angles BHF, BCD equal, it follows that the angle HBF is equal to the angle DBC, which is equal to BCA; and since HBD is equal to the angle A, and HBF equal to BCA, therefore FBD is the difference, and EBD half the difference of the two angles A and BCA; so making EB the radius, it is plain EC is the tangent of half the sum,

and ED the tangent of half the difference of the two angles at the base.

Now, IG being parallel to AC, the triangles HIG and HAC will be equiangular; consequently  $AH:IH::CH:GH$ ; but the wholes are as their halves, therefore  $AH:IH::\frac{1}{2}CH:\frac{1}{2}GH$ ; and since  $\frac{1}{2}CH$  is equal to EC, and  $\frac{1}{2}GH$  equal to FD=ED; therefore,  $AH:IH::EC::ED$ . Now, AH is the sum, and IH the difference of the sides; also EC is the tangent of half the sum, and ED the tangent of half the difference of the two angles at the base; consequently, in any triangle, as the sum of the sides is to their difference, so is the tangent of half the sum of the angles at the base, to the tangent of half their difference.

Theorem 3. If to half the sum of two quantities be added half their difference, the sum will be the greater of them; and if from half their sum be subtracted half their difference, the remainder will be the least of them.

Suppose the greater quantity to be  $x=8$ , and the lesser  $z=6$ ; then is their sum 14, and difference 2: wherefore, adding  $\frac{14}{2}=7$  to  $\frac{2}{2}=1$ , we get 8 the greatest of the two quantities; and, in the same manner,  $\frac{14}{2}-\frac{2}{2}=7-1=6$ , the least of the two quantities.

Theor. 4. In any right-lined triangle, ABD (N<sup>o</sup> 3.) the base AD is to the sum of the sides AB and BD, as the difference of the sides is to the difference of the segments of the base made by the perpendicular BE, viz. the difference between AE and ED.

Demon. Produce EB till BG be equal to BA the lesser leg; and on B as a center, with the distance BA or BG, describe the circle AGHF, which will cut BD and AD in the points H and F; then it is plain GD is the sum, and HD the difference of the sides; also since AE is equal to EF, therefore FD is the difference of the segments of the base; but  $AD:GD::HD:FD$ ; therefore the base is to the sum of the sides, &c. as was to be proved.

Having established these preliminary theorems, we shall now proceed to the solution of the six cases of oblique-angled plane trigonometry.

Case I. In any oblique-angled plane triangle, two sides and an angle opposite to one of them being given, to find the angle opposite to the other. Example: in the triangle ABC (N<sup>o</sup> 4.) suppose AB=156, BC=84, and the angle C (opposite to AB)=56° 30'; required the angle A, opposite to BC.

1. Geometrically: draw the line AC, and at any point of it, suppose C, make the angle C=56° 30'; then take CB=84, and with the length of 156=AB taken in your compasses from the same scale of equal parts, fixing one point in B, with

the other cross AC in A. Lastly, join A and B; so the triangle is constructed, and the required angle A may be measured by a line of chords.

2. By calculation: we have (by theor. 1.) the following proportion for finding the angle A, viz.

$$AB:BC::S,C:S,A.$$

|             |         |         |
|-------------|---------|---------|
| i. e. as AB | 156     | 2.19312 |
| to BC       | 84      | 1.92428 |
| so is S, C  | 56° 30' | 9.92111 |
| to S, A     | 26° 41' | 9.65227 |

Case II. The angles, and a side opposite to one of them, being given, to find a side opposite to another. Example: in the triangle HBG (N<sup>o</sup> 5.) suppose the angle H 46° 15', and the angle B 54° 22'; consequently the angle G 79° 23', and the leg HB 125, required HG.

1. Geometrically: draw HB 125, from any line of equal parts, and make the angle H 46° 15', and B 54° 22'; then produce the lines HG and BG till they meet one another in the point G; so the triangle is constructed, and HG is measured by taking its length in your compasses, and applying it to the same line of equal parts that HB was taken from.

2. By calculation: by the first of the preceding theorems, we have this analogy for finding HG, viz.

$$S,G:H B::S,B:H G.$$

|                        |         |         |
|------------------------|---------|---------|
| i. e. as the sine of G | 79° 23' | 9.99250 |
| is to the leg HB       | 125     | 2.09691 |
| so is the sine of B    | 54° 22' | 9.90996 |
| to the leg HG          | 103.4   | 2.01437 |

Case III. Two sides and an angle opposite to one of them given, to find the third side. Example: in the triangle KLM (N<sup>o</sup> 6.) suppose the side CL 126 equal parts, and KM 130 of these parts, and the angle L (opposite to KM) 63° 20', required the side ML.

1. Geometrically: the construction of this case is the same with that in Case I. (there being the same things given in both) and the leg ML may be measured by applying it to the same line of equal parts that the other two were taken from.

2. By calculation: the solution of this case depends upon the two preceding ones; and, first, we must find the other two angles by Case I. thus:

$$MK:S,L::KL:S,M.$$

|                      |         |         |
|----------------------|---------|---------|
| i. e. as the side MK | 130     | 2.11394 |
| to the sine of L     | 63° 20' | 9.95116 |
| so is the side KL    | 126     | 2.10037 |
| to the sine of M     | 60° 1'  | 9.93759 |

Then by Case II. we have the required leg ML, thus:

$$S,L:S,K::MK:ML.$$

|                        |         |         |
|------------------------|---------|---------|
| i. e. as the sine of L | 63° 20' | 9.95116 |
| to the sine of K       | 53° 39' | 9.90602 |
| so is MK               | 130     | 2.11394 |
| to ML                  | 117.2   | 2.06850 |

Case IV. Two sides and the contained angle being given, to find the other two angles. Example:

4 B in

# TRI

in the triangle ACD (N<sup>o</sup> 7.) suppose AC=103, AD=126, and the angle A=54° 30'; required the angles C and D.

1. Geometrically: draw AD=126, and make the angle A=54° 30'; then set off 103 equal parts from A to C. Lastly, join C and D; and so the triangle is constructed, and the angles C and D may be measured by a line of chords.

2. By calculation: the solution of this case depends upon the second and third of the preceding theorems; and first we must find the sum and difference of the sides, and half the sum of the unknown angles, thus:

|                                             |   |   |          |
|---------------------------------------------|---|---|----------|
| The leg AD is                               | — | — | 126      |
| the leg AC is                               | — | — | 130      |
| their sum is                                | — | — | 229      |
| and their difference is                     | — | — | 23       |
| the sum of the three angles A, D, and C, is | — | — | 180°     |
| the angle A is                              | — | — | 54° 30'  |
| so the sum of the angles C and D will be    | — | — | 125° 30' |
| and half their sum is                       | — | — | 62° 45'  |

Then by theor. 2. we have the following proportion, viz.

|                                                                         |   |   |          |
|-------------------------------------------------------------------------|---|---|----------|
| As the sum of the sides AD and AC=229                                   | — | — | 2.35984  |
| to their difference 23                                                  | — | — | 1.36173  |
| so is the tangent of half the sum of the unknown angles C and D 62° 45' | — | — | 10.28816 |
| to tangent of half their difference — 11° 2'                            | — | — | 9.29005  |

Now, having half the sum and half the difference of the two unknown angles C and D, we find the quantity of each of them by theorem 3. thus:

|                                             |   |         |
|---------------------------------------------|---|---------|
| To half the sum of the angles C and D, viz. | — | 62° 45' |
| add half their difference, viz.             | — | 11° 02' |

and the sum is the greater ang. C 73° 47'

|                                  |   |         |
|----------------------------------|---|---------|
| Again, from half their sum, viz. | — | 62° 45' |
| take half their difference, viz. | — | 11° 02' |

And there will remain the lesser angle D — = 51° 43'

N.B. The greater angle is always that subtended by the greater side; thus, in the present case, the greater angle C, is subtended by the greater side AD; and the lesser angle D, is subtended by the lesser side AC.

Case V. Two sides and the contained angle being given, to find the third side. Example: in the triangle BCD (N<sup>o</sup> 8.) suppose BC=154, BD=133, and the angle B=56° 03'; required the side CD.

1. Geometrically: the construction of this case is

# TRI

the same with that of the last, and the length of DC is found by taking its length in your compasses, and applying it to the same line of equal parts that the two legs are taken from.

2. By calculation: the solution of this case depends upon the second and fourth; and first we must find the angles by the last case; thus:

|                                                                   |   |   |          |
|-------------------------------------------------------------------|---|---|----------|
| As the sum of the sides BD and BC 287                             | — | — | 2.45788  |
| is to their difference 21                                         | — | — | 1.32222  |
| so is the tangent of half the sum of the angles D and C — 61° 58' | — | — | 10.27372 |
| to the tangent of half their difference 7.50                      | — | — | 9.13806  |

So by theorem 3. we have the angles D and C, thus:

|                                       |   |         |
|---------------------------------------|---|---------|
| To half the sum of the angles D and C | — | 61° 58' |
| add half their difference             | — | 7° 50'  |
| and the sum is the greater angle D    | — | 69° 48' |
| Also, from half the sum               | — | 61° 58' |
| take half the difference              | — | 7° 50'  |
| and there remains the lesser angle C  | — | 54° 08' |

Then by Case II. we have the following analogy for finding DC the leg required, viz.

|                                |         |
|--------------------------------|---------|
| S, C: BD:: S, B: DC.           |         |
| i. e. As the sine of C 54° 08' | 9.90869 |
| To B D — 133                   | 2.12385 |
| So is the sine of B 56° 03'    | 9.91883 |
| To D C — 136.2                 | 2.13399 |

Case VI. Three sides, being given, to find the angles.

Example: In the triangle ABC (No 9.) suppose AB=156, AC=185.7, and BC=84; required the angles A, B, and C.

1. Geometrically: Make AC=185.7, from any line of equal parts; and from the same line taking 156=AB in your compasses, fix one foot of them in A, and with another sweep an arch; then take 84=BC in your compasses, and fixing one foot in C, with another sweep an arch, which will cross the former in B: lastly, join the points B and A, and B and C; so the triangle will be constructed, and the angles may be measured by a line of chords.

2. By calculation: Let fall the perpendicular, BD, from the vertex B, upon the base AC; which will divide the base into two segments AD and DC, the length whereof may be found by theorem 4, thus:

|                                       |   |         |
|---------------------------------------|---|---------|
| As the base AC — 185.7                | — | 2.26893 |
| To the sum of the sides AB and BC 240 | — | 2.38031 |
| So is the diff. of the sides 72       | — | 1.83733 |

|                                             |   |         |
|---------------------------------------------|---|---------|
| To the diff. of the segments of the base 93 | — | 1.96871 |
|---------------------------------------------|---|---------|

And having the sum of the segments, viz. the whole

# TRI

whole base, and their difference, we find the segments themselves, by theorem 3, thus:

To half the sum of the segments — — 92.8  
And half their difference — — 46.5

And the sum is the greater segment AD 139.3  
Also from half the sum of the segment — 92.8  
Take half their difference — — 46.5

The remainder is the lesser segment DC 46.3

Now the triangle ABC is divided by the perpendicular DB, into two right-angled triangles, ADB, and DBC; in the first of which are given the hypotenuse AB = 156, and the base AD = 139.3, to find the oblique angles, for which we have (by Case V. of rectangular trigonometry) the following analogy, viz.

As AB — — — 156 2.19312  
To AD — — — 139.3 2.14395  
So is the radius — — 90° 10.00000

To the co-sine of the angle A 26° 40' 9.95038

Also the angle C is found by the same case, thus:

As BC — — — 44 — — 1.92428  
To CD — — — 46.3 — — 1.66558  
So is the radius 90° — — 10.00000

To the co-sine of C 56° 30' — — 9.74130

Having found the two angles A and C, we have the third, B, by taking the sum of the other two from 180, thus:

The sum of all the three angles is — 180°

The sum of A and C is — — 83° 10'

The angle B is — — — 96° 50'

All the proportions used for the solutions of the several cases in plain trigonometry, may be performed by the scale and compass. On the scale there are several logarithmic line, viz. one of numbers, another of sines, and one of tangents, &c. See the articles SCALE.

And the way of working a proportion by these is this, viz. extend your compasses from the first term of your proportion, found on the scale, to the second, and with that extent, fixing one foot in the third term, the other will reach the fourth term required.

**Spherical TRIGONOMETRY**, is the art whereby, from three given parts of a spherical triangle, we discover the rest; and, like plane trigonometry, is either right-angled, or oblique-angled. But before we give the analogies for the solution of the several cases in either, it will be proper to premise the following theorems.

**Theorem 1.** In all right-angled spherical triangles, the sine of the hypotenuse : radius :: sine of a leg : sine of its opposite angle. And the sine of a leg : radius :: tangent of the other leg : tangent of its opposite angle.

**Demonstration :** Let EDAFG (fig. 4. N° 1.)

# TRI

represent the eighth part of a sphere, where the quadrantal planes EDFG, EDBC, are both perpendicular to the quadrantal plane ADFB; and the quadrantal plane ADGC is perpendicular to the plane EDFG; and the spherical triangle ABC is right-angled at B, where CA is the hypotenuse, and BA, BC, are the legs.

To the arches GF, CB, draw the tangents HF, OB, and the sines GM, CI, on the radius DF, DB; also draw BL the sine of the arch AB, and CK the sine of AC; and then join IK and OL. Now HF, OB, GM, CI, are all perpendicular to the plane ADFB. And HD, GK, OL, lie all in the same plane ADGC. Also FD, IK, BL, lie all in the same plane ADGC. Therefore, the right-angled triangles HFD, CIK, ODL, having the equal angles HDF, CKI, OLB, are similar. And CK : DG :: CI : GM; that is, as the sine of the hypotenuse : rad. :: sine of a leg : sine of its opposite angle. For GM is the sine of the arc GF, which measures the angle CAB. Also, LB : DF :: BO : FH; that is, as the sine of a leg : rad. :: tang. of the other leg : tang. of its opposite angle. Q. E. D.

Hence it follows, that the sines of the angles of any oblique spherical triangle ACD (N° 2.) are to one another, directly, as the sines of the opposite sides. Hence it also follows, that, in right-angled spherical triangles, having the same perpendicular, the sines of the bases will be to each other, inversely, as the tangents of the angles at the bases.

**Theorem 2.** In the right-angled spherical triangle ABC (N° 3.) it will be, as radius is to the co-sine of one leg, so is the co-sine of the other leg to the co-sine of the hypotenuse.

Hence, if two right-angled spherical triangles ABC, CBD (N° 2.) have the same perpendicular BC, the co-sines of their hypotenuses will be to each other, directly, as the co-sines of their bases.

**Theorem 3.** In any spherical triangle it will be, as radius is to the sine of either angle, so is the co-sine of the adjacent leg to the co-sine of the opposite angle.

Hence, in right-angled spherical triangles, having the same perpendicular, the co-sines of the angles at the base will be to each other, directly, as the sines of the vertical angles.

**Theorem 4.** In any right-angled spherical triangle it will be, as radius is to the co-sine of the hypotenuse, so is the tangent of either angle to the co-tangent of the other angle.

As the sum of the sines of two unequal arches is to their difference, so is the tangent of half the sum of those arches to the tangent of half their difference: and, as the sum of the co-sines is to their difference, so is the co-tangent of half the sum of the arches to the tangent of half the difference of the same arches.

**Theorem 5.** In any spherical triangle ABC (N°

(N<sup>o</sup> 4 and 5.) it will be, as the co-tangent of half the sum of the two sides is to the tangent of half their difference, so is the co-tangent of half the base to the tangent of the distance (D E) of the perpendicular from the middle of the base.

Since the last proportion, by permutation, becomes co-tang.  $\frac{AC+BC}{2}$  : co-tang. A E :: tang.  $\frac{AC-BC}{2}$  : tang. D E, and as the tangents of any two arches are, inversely, as their co-tangents; it follows, therefore, that tang. A E : tang.  $\frac{AC+BC}{2}$

:: tang.  $\frac{AC-BC}{2}$  : tang. D E; or, that the tangent of half the base is to the tangent of half the sum of the sides, as the tangent of half the difference of the sides to the tangent of the distance of the perpendicular from the middle of the base.

Theorem 6. In any spherical triangle A B C (N<sup>o</sup> 4.) it will be, as the co-tangent of half the sum of the angles at the base, is to the tangent of half the vertical angle to the tangent of the angle which the perpendicular C D makes with the line C F bisecting the vertical angle.

The Solution of the Cases of right-angled spherical Triangles, (fig. 4. N<sup>o</sup> 3.)

| Case | Given                                | Sought               | Solution                                                                            |
|------|--------------------------------------|----------------------|-------------------------------------------------------------------------------------|
| 1    | The hyp. A C and one angle A         | The opposite leg B C | As radius : sine hyp. A C :: sine A : sine B C (by the former part of theor. 1.)    |
| 2    | The hyp. A C and one angle A         | The adjacent leg A B | As radius : co-sine of A :: tang. A C : tang. A B (by the latter part of theor. 1.) |
| 3    | The hyp. A C and one angle A         | The other angle C    | As radius : co-sine of A C :: tang. A : co-tang. C (by theorem 4.)                  |
| 4    | The hyp. A C and one leg A B         | The other leg B C    | As co-sine A B : radius :: co-sine A C : co-sine B C (by theorem 2.)                |
| 5    | The hyp. A C and one leg A B         | The opposite angle C | As sine A C : radius :: sine A B : sine C (by the former part of theorem 1.)        |
| 6    | The hyp. A C and one leg A B         | The adjacent angle A | As tang. A C : tang. A B :: radius : co-sine A (by theorem 1.)                      |
| 7    | One leg A B and the adjacent angle A | The other leg B C    | As radius : sine A B :: tangent A : tangent B C (by theorem 4.)                     |
| 8    | One leg A B and the adjacent angle A | The opposite angle C | As radius : sine A :: co-sine of A B : co-sine of C (by theorem 3.)                 |
| 9    | One leg A B and the adjacent angle A | The hyp. A C         | As co-sine of A : radius :: tang. A B : tang. A C (by theorem 1.)                   |
| 10   | One leg B C and the opposite angle A | The other leg A B    | As tang. A : tang. B C :: radius : sine A B (by theorem 4.)                         |
| 11   | One leg B C and the opposite angle A | The adjacent angle C | As co-sine B C : radius :: co-sine of A : sin. C (by theorem 3.)                    |
| 12   | One leg B C and the opposite angle A | The hyp. A C         | As sin. A : sin. B C :: radius : sin. A C (by theorem 1.)                           |
| 13   | Both legs A B and B C                | The hyp. A C         | As radius : co-sine A B :: co-sine B C : co-sine A C (by theorem 2.)                |
| 14   | Both legs A B and B C                | An angle, suppose A  | As sine A B : radius :: tang. B C : tang. A (by theorem 4.)                         |
| 15   | Both angles A and C                  | A leg, suppose A B   | As sine A : co-sine C :: radius : co-sine A B (by theorem 3.)                       |
| 16   | Both angles A and C                  | The hyp. A C         | As tang. A : co-sine C :: radius : co-sine A C (by theorem 4.)                      |

Note. The 10th, 11th, and 12th cases are ambiguous; since it cannot be determined by the data, whether A B, C, and A C, be greater or less than 90 degree each.

The Solution of the Cases of oblique spherical Triangles, (fig. 4. N<sup>o</sup> 4 and 5.)

| Case | Given                                                       | Sought                                 | Solution                                                                                                                                                                                                                                                   |
|------|-------------------------------------------------------------|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1    | Two sides A C, B C, and an angle A opposite to one of them  | The angle B opposite to the other      | As sine B C : sine A :: sine A C : sine B (by theor. 1.) Note, this case is ambiguous when B C is less than A C; since it cannot be determined from the data whether B be acute or obtuse.                                                                 |
| 2    | Two sides A C, B C, and an angle A opposite to one of them. | The included angle A C A               | Upon A B produced (if need be) let fall the perpendicular C D : then (by theor. 4.) rad. : co-sine A C :: tang. A : co-tang. A C D ; but (by theorem 1.) as tang. B C : tang. A C :: co-sine A C D : co-sine B C D. Whence A C B = A C D ± B C D is known. |
| 3    | Two sides A C, B C, and an angle opposite to one of them    | The other side A B                     | As rad. : co-sine A :: tang. A C : tang. A D (by theor. 1.) and (by theor. 2.) as co-sine A C : co-sine B C :: co-sine A D : co-sine B D. Note, this and the last case are both ambiguous when the first is so.                                            |
| 4    | Two sides A C, A B, and the included angle A.               | The other side B C                     | As rad. : co-sine A :: tang. A C : tang. A D (by theor. 1.) whence B D is also known : then (by theor. 2.) as co-sine A D : co-sine B D :: co-sine A C : co-sine B C.                                                                                      |
| 5    | Two sides A C, A B, and the included angle A                | Either of the other angles, suppose B  | As rad. : co-sine A :: tang. A C : tang. A D (by theorem 1.) whence B D is known : then (by theor. 4.) is sine B D : sine A D :: tang. A : tang. B.                                                                                                        |
| 6    | Two angles A, A C B, and the side A C betwixt them          | The other angle B                      | As rad. : co-sine A C :: tang. A : co-tang. A C D (by theor. 4.) whence B C D is also known : then (by theor. 3.) as sine A C D : sine B C D :: co-sine A : co-sine B.                                                                                     |
| 7    | Two angles A, A C B, and the side A C betwixt them          | Either of the other sides, suppose B C | As rad. : co-sine A C :: tang. A : co-tang. A C D (by theo 4.) whence B C D is also known : then, as co-sine B C D : co-sine A C D :: tang. A C tang. B C (by theor. 1.)                                                                                   |
| 8    | Two angles A, B, and a side A C opposite to one of them     | The side B C opposite the other        | As sine B : sine A C :: sine A : sine B C (by theorem 1.)                                                                                                                                                                                                  |
| 9    | Two angles A, B, and a side A C opposite to one of them     | The side A B betwixt them              | As rad. : co-sine A :: tang. A C : tan. A D (by theor. 1.) and as : tang. B : tang. A :: sine A D : sine B D (by theor. 4.) whence A B is also known.                                                                                                      |
| 10   | Two angles A, B and a side A C opposite to one of them      | The other angle A C B                  | As rad. : co-sine A C :: tang. A : co-tang. A C D (by theor. 4.) and as co-sine A : co-sine B :: sine A C D : sine B C D (by theor. 3) whence A C B is also known.                                                                                         |

| Case | Given                                 | Sought                 | Solution                                                                                                                                                                                                                                                                                        |
|------|---------------------------------------|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 11   | All the three sides<br>AB, AC, and BC | An angle, suppose<br>A | As tang. $\frac{1}{2}$ A B : tang. $\frac{AC + BC}{2}$ ::<br>tang. $\frac{AC - BC}{2}$ : tang. DE, the dif-<br>ference of the perpendicular from the<br>middle of the base (by theorem 6.)<br>whence AD is known : then, as tang.<br>AC : tang. AD :: rad. : co-sine A (by<br>theorem 1.)       |
| 12   | All the three angles<br>A, B, and ACB | A side, suppose<br>AC  | As co-tang. $\frac{ABC + A}{2}$ : tang. $\frac{ABC - A}{2}$<br>:: tang. $\frac{ACB}{2}$ : tang. of the angle in-<br>cluded by the perpendicular and a line<br>bisecting the vertical angles ; whence<br>ACD is also known : then (by theor.<br>5.) tang. A : co-tang. ACD : rad.<br>co-sine AC. |

Note, in letting fall your perpendicular, let it always be from the end of a given side, and opposite to a given angle.

**TRILLION**, in arithmetic, a billion of billions.  
See NUMERATION.

**TRILLIUM**, in botany, a genus of plants, whose flower consists of three oval petals, and six tubulated filaments, terminated with oblong antheræ, which are the length of the filaments ; the fruit is a roundish trilocular berry, containing a number of roundish seeds.

**TRILLO**, in music, the same with cadence.  
See CADENCE.

**TRIM** of a Ship, her best posture, proportion of ballast, and hanging of her yards, &c. for sailing.

To find the trim of a ship, is to find the best way of making her sail swiftly, or how she will sail best. This is done by easing of her masts and throwds ; some ships sailing much better when they are slack, than when they are taut or fast : but this depends much upon experience and judgment, and the several trials and observations which the commander and other officers may make on board.

**TRIMMERS**, in architecture, pieces of timber framed at right-angles to the joints, against the ways for chimneys, and well-holes for stairs.

**TRINGLE**, in architecture, a name common to several little square members or ornaments, as reglets, listels, and plat-bands.

**TRINGLE**, is more particularly used for a little member fixed exactly over every triglyph, under the plat-band of the architrave, from whence the guttæ or pendant-drops hang down.

**TRINITARIANS**, those who are orthodox and believe in the Trinity ; those who do not believe

therein, being called Antitrinitarians. See ANTI-TRINITARIANS.

**TRINITARIANS**, also denote an order of religious, instituted at Rome in the year 1198, under the pontificate of Innocent III. the founders whereof were John de Matha, and Felix de Valois. His holiness gave them permission to establish this order for the deliverance of captives, who groaned under the tyranny of the infidels ; he gave them, as a habit, a white gown ornamented with a red and blue cross.

**TRINITY**, *Trinitas*, in theology, the ineffable mystery of three persons in one God ; Father, Son, and Holy Spirit.

The doctrine of the Trinity, as professed in the Christian church, is as follows : that there is but one God in three distinct persons, Father, Son, and Holy Ghost ; *person* signifying the same as *essence*, with a particular manner of subsistence, which the Greek fathers call *hypostasis*, taking it for the incommunicable property that makes a person.

The Father, Son, and Holy Ghost, are believed to be three distinct persons in the divine nature, because the scriptures, in speaking of these three, distinguish them from one another, as we use in common speech, to distinguish three several persons. There are many instances to this purpose, particularly the form of administering the sacrament of baptism, which runs in the name of the Father, the Son, and the Holy Ghost ; and that solemn benediction with which St. Paul ends his second Epistle to the Corinthians, " The grace of our Lord Jesus Christ

Christ, &c." and the three witnesses in heaven, mentioned by St. John. Each of these three persons are affirmed to be God, because the names, properties, and operations of God are, in the Holy Scriptures, attributed to each of them.

The divinity of the Father is indisputed; that of the Son is proved from the following texts, among many others: St. John says, "The Word was God;" St. Paul, "That God was manifested in the flesh; that Christ is over all, God blessed for ever." Eternity is attributed to the Son; "The Son hath life in himself:" perfection of knowledge: "As the Father knoweth me, so know I the Father." And we are commanded to "Honour the Son as we honour the Father."

The divinity of the Holy Ghost rests upon the following proofs, among others: Lying to the Holy Ghost, is called "Lying to God;" because Christians are the temples of the Holy Ghost, they are said to be the "Temples of God." "His teaching all things; his guiding into all truth; his telling things to come; his searching all things, even the deep things of God, &c." are adduced as plain characters of his divinity. Besides, he is joined with God the Father, as an object of faith and worship, in baptism, and the apostolical benediction.

Many of the heathens seem to have had a notion of the Trinity in the Godhead; Plato and his followers speak of it in such terms, that the primitive fathers have been accused of borrowing the doctrine itself from the Platonic school. This point is treated at large in Cudworth's Intellectual System.

TRINITY-SUNDAY, a festival of the Christian church, observed on the Sunday next after Whit-sunday, in honour of the holy and undivided Trinity. The observation of this festival was first enjoined in the council of Arles, anno 1260.

TRINOMIAL, or TRINOMIAL ROOT, in mathematics, is a root consisting of three parts connected together by the signs  $+$  or  $-$ ; as  $x+y+z$ , or  $a+b-c$ .

TRIO, in music, a part of a concert wherein three persons sing; or, more properly, a musical composition consisting of three parts.

Trios are the finest kinds of composition, and these are what please most in concerts.

TRIONES, in astronomy, a sort of constellation or assemblage of several stars in the Ursa Minor, commonly called Charles's Wain. See the article URSA.

TRIOPTERIS, in botany, a genus of plants, whose flower consists of five roundish concave petals and ten capillary filaments, topped with roundish erect antheræ: there is no pericarpium, but the flower is succeeded by three erect seeds, which are carinated on their backs.

TRIOSTEUM, in botany, a genus of plants, whose flower is monopetalous and tubulose, contain-

ing five slender filaments the length of the corolla, and topped with oblong antheræ: the fruit is an oval berry, having three cells, each containing an obtuse, three-cornered, osseous seed.

This genus comprehends the *triosteospermum* of Dillenius.

TRIOURS, in law, are such persons as are chosen by the court to examine whether a challenge made to the whole panel of jurors, or any part of them, be just or not.

TRIPARTITE, *Tripartitus*, something divided into three parts, or made by three parties, as indenture tripartite, &c.

TRIPARTITION, a division by three, or the taking the third part of any number or quantity.

TRIPETALOUS FLOWERS, among botanists, are those whose corolla consists of three leaves, or petals.

TRIPHTHONG, in grammar, an assemblage or concurrence of three vowels in the same syllable, as *que*.

TRIPLARIS, in botany, a genus of plants, whose flower consists of three petals, with three subulated filaments, terminated with ovate, linear, membranaceous antheræ: there is no pericarpium; but the seed, which is an ovate nut, is contained in the tube of the cup.

TRIPLE, threefold. See the articles RATIO and SUB-TRIPLE.

TRIPLE, in music, is one of the species of measure or time.

Triple-time consists of many different species, whereof there are in general four, each of which has its varieties. The common name triple is taken hence, that the whole half of the bar is divisible into three parts, and is beaten accordingly.

TRIPlicate RATIO, the ratio which cubes bear to one another.

This ratio is to be distinguished from triple-ratio, and may be thus conceived: in the geometrical proportions 2, 4, 8, 16, 32, as the ratio of the first term (2) is to the third (8) duplicate of that of the first to the second, or of the second to the third, so the ratio of the first to the fourth is said to be triplicate of the ratio of the first to the second, or of that of the second to the third, or of that of the third to the fourth, as being compounded of three equal ratios.

TRIPOD, *Tripod*, in antiquity, a famed sacred seat or stool, supported by three feet, whereon the priests and sibyls were placed to render oracles.

TRIPOLI, in natural history, the name of an earthy substance much used by the lapidaries to polish stones, and by the brassiers, and other the like artists, to clean metalline vessels. It is of two kinds, the yellowish and reddish-white; the yellowish-white kind is called by authors *alana gleba*, *tripolis* and *terra tripolitana*; this is the produce of Ger-

Germany Saxony, and France; there is also of it in the neighbourhood of Venice, but it is found in greatest plenty in many parts of Africa. It is found a dry hard earth of a very pale yellowish-white, of a firm texture and moderately heavy; it is sometimes found of itself, constituting a stratum; but it is more frequently met with in detached pieces among strata of other matter. It is of a rough, irregular dusty surface; it adheres slightly to the tongue, is dry, hard, and harsh to the touch, is not to be broken between the fingers, and slightly stains the hands: it makes no effervescence with aqua-fortis, and makes a slight hissing noise on being thrown into water. The reddish tripoli is of our own production though not peculiar to our country; it is found in great abundance on Mendip-hills in Somersetshire, and not less plentifully in many parts of Germany. This is well known in the shops as a substance of great use in polishing brass, but is not applied to any of the other uses of the yellowish kind: this, like the former, is most frequently found in detached masses, and while in the earth is tolerably soft, and easily falls into flakes. When dry it becomes of a considerable hardness, and is of a fine pale reddish white, of a loose open texture, composed of a multitude of extremely thin plates or flakes laid evenly on one another, and considerably heavy; it is of a smooth and somewhat glossy surface; it adheres very firmly to the tongue, is dry and harsh to the touch, too hard to be broken between the fingers, and does not stain the hands: it makes no effervescence with acids, and burns to a paler colour, with some additional hardness.

TRIPPING, in heraldry, denotes the quick motion of all sorts of deer, and of some other creatures, represented on one foot as it were on a trot.

TRIPTOTES, *Triptota*, in grammar, defective nouns which have only three cases; such is *mele, tempe, grates, prece, &c.*

TRISECTION, or TRISSECTION, the dividing a thing into three. The term is chiefly used in geometry, for the division of an angle into three equal parts. The trisection of an angle geometrically, is one of those great problems whose solution has been so much sought by mathematicians for these two thousand years, being in this respect on a footing with the quadrature of a circle, and the duplication of the cube angle.

TRISMEGISTUS, an epithet or surname given to one of the two Hermetes, or Mercuries, kings of Thebes in Egypt, who is said to be cotemporary with Moses.

TRISPAST, *Trispaston*, in mechanics, a machine with three pulleys or an assemblage of three pulleys for raising of great weights.

TRITICUM, wheat in botany. See the article WHEAT,

TRITON, in ichthyology, a genus of fish, the body of which is oblong, the rostrum at the mouth of a spiral form, the tentacula fourteen in number, and twelve of them cheliferous.

TRITON, in poetry, a sea demi-god, held by the ancients to be an officer or trumpeter of Neptune, attending on him, and carrying his orders and commands from sea to sea.

TRITONE, *Tritono*, in music, a false concord consisting of three tones, or a greater third and a greater tone.

TRITURATION, *Tritura*, in pharmacy, the act of reducing a solid body into a subtile powder; called also levigation and pulverization.

This is principally employed to reduce hard substances to fine powders, either by the mortar or by way of levigation on a marble: there is little difficulty in this, besides the labour. Trituration has a great share in some instances, in raising or depressing the efficacy of what comes under its management; for in grinding all those bodies, whose efficacy consists in the peculiar shape and points of their component parts, the more and finer they are broke, the less they will operate: thus may calomel be rendered much gentler, and made capable of being given in much larger quantities, only by long rubbing in a glass mortar; for the continual triture has the same effect upon it, as repeated sublimation, which is only breaking of the saline spicula more and more, until it becomes almost plain mercury. But in resinous substances, particularly those which are purgative, as jalap, scammony, &c. the finer the powder they are reduced into, the greater their efficacy is likely to be. As the sense which the stomach and bowels have of them is in proportion to their contacts, therefore the more the same quantity is divided, the farther will it diffuse itself, and vellicate the fibres; that is, in other words, it will work the more.

TRITURATION is also used in medicine for the action of the stomach on the food, whereby it is fitted for nourishment.

TRIUMFETTA, in botany, a plant, which grows naturally in the West-Indian islands, where it rises, with an upright stem, to the height of six or seven feet, which becomes ligneous toward the bottom, and divides upward into four or five branches, which are furnished with leaves placed alternately their whole length, these are about two inches and a half long, and almost two inches broad toward the base, divided almost into three lobes toward the top, and the middle division ending in an acute point; they are veined on their under side, are covered with a soft brown down, and have several veins running from the mid-rib to the sides; their upper surface is of a yellowish green, and a little hairy, their borders are acutely but unequally sawed, and stand upon footstalks an inch long; the branches are terminated by long spikes of flowers, which

which come out in clusters from the side of the principal footstalk, and are of a yellow colour, each containing five linear, concave, obtuse and erect petals, with sixteen subulated stamina: the fruit is a globose capsule, every where surrounded with hooked prickles, and contains four cells, each inclosing a seed, which is convex on one side, and angular on the other; this plant generally flowers here in July and August, and is propagated by sowing the seeds on a hot bed in the spring, which when come up should be planted singly in pots, and plunged in the bark bed in the stove, where they must continually be kept.

**TRIUMPH**, in Roman antiquity, a public and solemn honour conferred by the Romans on a victorious general, by allowing him a magnificent entry into the city. The triumph was of two kinds, the lesser, and the greater, the first of which is the same with the ovation. See **OVATION**.

The greater triumph, called also *curulis*, or simply the triumph, was decreed by the senate to a general, upon the conquering of a province, or gaining a signal victory.

The day appointed for the ceremony being arrived, scaffolds were erected in the forum and circus, and all the other parts of the city, where they could best behold the pomp: the senate went to meet the conqueror without the gate called *capena* or *triumphalis*, and marched back in order to the capitol; the ways being cleared by a number of officers and tipstaves, who drove away such as thronged the passage, or straggled up and down. The general was clad in a rich purple robe, interwoven with figures of gold, setting forth his great exploits; his buskins were beset with pearl, and he wore a crown, which at first was only laurel, but afterwards gold; in one hand he bore a branch of laurel, and in the other a truncheon. He was drawn in a magnificent chariot, adorned with ivory and plates of gold, drawn usually by two white horses; though sometimes by other animals, as that of Pompey, when he triumphed over Africa, by elephants; that of Marc Antony, by lions; that of Heliogabalus, by tygers; that of Aurelian, by deer, &c. His children were at his feet, and sometimes on the chariot horses. The procession was led up by the musicians, who played triumphal pieces, in praise of the general: these were followed by young men, who led the victims to the sacrifice, with their horns gilded, and their heads adorned with ribbands and garlands; next came the cars and waggons, loaded with all the spoils taken from the enemy, with their horses, chariots, &c. these were followed by the kings, princes, and generals, who had been taken captives, loaden with chains: after these appeared the triumphal chariot, before which, as it passed, they all along strewed flowers, and the people, with loud acclamations, called out *Io triumphe!* The

chariot was followed by the senate, clad in white robes; and the senate by such citizens as had been set at liberty or ransomed: and the procession was closed by the priests and their officers and utensils, with a white ox led for the chief victim. In this order they proceeded through the triumphal gate, along the *via-sacra*, to the capitol, where the victims were slain. In the mean time all the temples were open, and all the altars loaded with offerings and incense; games and combats were celebrated in the public places, and rejoicings appeared every where.

**TRIUMVIR**, one of the three persons who govern absolutely, and with equal authority, in a state.

**TRIUMVERATE**, an absolute government administered by three persons, with equal authority.

**TROCHAIC VERSE**, in the latin poetry, a kind of verse, so called because the trochees chiefly prevail, as the iambus does in the iambic. It generally consists of seven feet and a syllable; the odd feet, for the most part, consist of trochees, though a tribrachys is sometimes admitted, except in the seventh foot: these two feet are likewise used in the other places, as is also the spondaeus, dactylus, and anapaestus. The following is an example.

1 2 3 4 5 6 7  $\frac{1}{2}$   
Solus | aut rex | aut po | eta | non quot | annis | nasci | tur.

**TROCHANTER**, in anatomy, a name given, to two apophyses, situated in the upper part of the thigh bone: they receive the tendons of most of the muscles of the thigh. See the article **FEMUR**.

**TROCHE**, *Trochiscus*, in pharmacy, a sort of medicine made of glutinous substances, into little cakes, and afterwards excicated. The four following rules are to be observed in making of them: 1. The ingredients are to be reduced to a powder. 2. If the mass proves so glutinous as to stick to the fingers in making up, the hands may be anointed with any convenient sweet or aromatic oil; or else sprinkled with powder of starch, or with that of liquorice. 3. In order to dry thoroughly the troches, put them on an inverted sieve, in a shady airy place, and frequently turn them. 4. The troches are to be kept in glass vessels, or in earthen ones well glazed. There are troches of various kinds, and for various intentions, as purgative, alterative, aperitive, corroborative, &c. The chief troches now in use are those of myrrh and liquorice, and those of the testaceous powders for the heart-burn.

**TROCHEE**, *Trocheus*, in the Greek and Latin poetry, a foot consisting of two syllables, the first long, and the second short, as in the words *mūsā* and *servāt*.

**TROCHILUS**, in architecture, a name used by the antients for what the moderns call *scotia*.

**TROCHLEA**, one of the mechanical powers, usually called a pulley. See the article **PULLEY**.

**TROCHLEARES**, in anatomy a name given to the oblique muscles of the eye.

**TROCHOID**, in geometry, a curve more generally known by the name of cycloid.

**TROLLIUS**, in botany, a genus of plants, whose flower consists of fourteen almost oval petals, whose points meet together, with nine linear, plane, incurved nectariums, and a great number of feaceous filaments topped with erect antheræ; the fruit consists of a number of capsules, collected into an ovate head, each containing a single seed.

**TRONAGE**, an antient customary toll, paid for weighing of wool. This word is particularly mentioned in a charter granted to the mayor and citizens of London; in which city there is an officer called tronator, whose business it is to weigh the wool that is brought thither.

**TROOP**, a small body of horse or dragoons, about fifty or sixty, sometimes more, sometimes less; commanded by a captain. Each troop, besides a captain, has a lieutenant, cornet, quarter-master, and three corporals, who are the lowest officers of a troop.

**TROPÆOLUM**, Indian cress, in botany, a genus of plants, whose flower consists of five roundish petals, inserted into the divisions of the cup; the two upper ones set close to the foot stalk; the three others have very long and barbed ungues; the stamina are eight short subulated, declining, unequal filaments, topped with oblong assurgent, erect antheræ; the fruit consists of three furrowed berries, convex on the outside, and angulated within, each containing a single seed, gibbous on one side, angular on the other and striated.

The Indian cress, is easily propagated by the seeds being sown in the spring, where they are intended to perfect themselves, the flowers are frequently eaten in sallads, having a warm taste like the garden cress, and are reckoned very wholesome; the seeds are often pickled, and are by many esteemed preferable to any kind of pickle now used, a variety of this plant producing double flowers, is much esteemed for its beauty, but as the plentitude of the petals destroys its generative functions, there is no other method of increasing it, than by layers or cuttings, which being performed in any of the summer months they take root very freely, but being of a tender nature, they require a hot house for their preservation in winter.

**TROPE**, in rhetoric, a kind of figure of speech, whereby a word is removed from its first and natural signification, and applied with advantage to another thing, which it does not originally mean; but only stands for it, as it has a relation to, or connection with it: as in this sentence, *God is my rock*. Here the trope lies in the word *rock*, which being firm and immoveable, excites in our minds the notion of God's unfailing power, and the steady support which

good men receive from their dependence upon him.

Tropes are used for the sake of an agreeable variety; they divert the mind and revive attention, when it begins to flag and be weary. In many cases there is an absolute necessity for the writer or speaker to repeat the same thing several times; therefore to prevent the tiresome repetition of the same words, he carefully diversifies his expressions, and judiciously intermixes plain and figurative language. Tropes add a wonderful ornament and strength to a discourse, and often give the mind a brighter and stronger idea of a thing, than proper words: Thus Virgil calling the two Scipios the *thunder-bolts of war*, represents the rapid speed and victorious progress of their arms more emphatically, than all the plain terms of the Roman language could have done. In order to make use of tropes seasonably, and with advantage, the following rules should be observed: 1. Be sparing and cautious in the use of them, and omit them when they are not either as plain as proper words, or more expressive: tropes are the riches of a language, and it will be an imputation upon a man to lavish them away without discretion. 2. Care must be taken, that tropes hold a proportion to the ideas intended to be raised by them; there ought to be an easy and unforced relation betwixt the trope and the proper word it is put for, or the thing intended to be expressed by it: when there is not this suitableness and relation, the expression at best will not only be harsh and unpleasant, but often ridiculous and barbarous. In order to preserve this relation, a trope ought not to express more or less than the thing requires; and things capable of heightening or ornament ought not to be debased nor vilified by low expressions; nor small matters over-magnified by pompous and swelling words. 3. A trope ought to be obvious and intelligible, and therefore must not be fetched from things too remote, so as to require much reading and learning to apprehend it.

**TROPHIS**, in botany, a genus, producing male and female flowers on distinct plants; the corolla of the male consists of four obtuse patent petals, with four capillary stamina the length of the petals; the female flower hath no corolla, but consists of a small cup composed of one leaf, with an ovate germen, and slender and bipartite pistil; the fruit is a rough unilocular berry, slightly furrowed, and contains an almost globular seed.

**TROPHY**, *Tropæum*, among the antients, a pile or heap of arms of a vanquished enemy, raised by the conqueror in the most eminent part of the field of battle.

The trophies were usually dedicated to some of the gods, especially Jupiter. The name of the deity to whom they were inscribed, was generally mentioned, as was that also of the conqueror. The spoils were at first hung upon the trunk of a tree; but

but instead of trees, succeeding ages erected pillars of stone, or brass, to continue the memory of their victories. To demolish a trophy was looked upon as a kind of sacrilege, because they were all consecrated to some deity.

The representation of a trophy is often to be met with on medals of the Roman emperors; struck on occasion of victories; wherein, besides arms and spoils, are frequently seen one or two captives by the sides of the trophy.

TROPHY-MONEY, denotes certain money annually raised in the several counties of the kingdom, towards providing harness, and maintaining the militia.

TROPICS, in astronomy and geography, are two circles supposed to be drawn on each side of the equinoctial, and parallel thereto. That on the North-side of the line is called tropic of cancer, and the Southern tropic has the name of Capricorn, as passing through the beginning of those signs. They are distant from the equinoctial  $23^{\circ} 29'$ . Two circles drawn at the same distance from the equator on the terrestrial globe, have the same names in geography, and they include that space or part of the sphere, which is called the torrid zone, because the sun is, at one time or other, perpendicular over every part of that zone, and extremely torrifies or heats it.

TROT, in the manege, one of the natural paces of a horse performed with two legs in the air, and two on the ground at the same time cross-wise, like St. Andrew's cross, and continuing so alternately to raise the hind-leg of the one side, and the fore-leg of the other side at once, leaving the other hind and fore-leg upon the ground, till the former come down. In this motion the nearer the horse takes his limbs from the ground, the opener, the evenner and shorter his trot will be. If he takes up his feet slovenly, it is a sign of stumbling and lameness; if he treads narrow or cross, it betokens interfering or failing; if he treads long, it shews over-reaching; if he steps uneven, it bespeaks toil and weariness.

TROVER, in law, an action which a man hath against one that, having found any of his goods, refuseth to deliver them upon demand.

TROUGH of the Sea, is the hollow or cavity made between two waves or billows, in a rolling sea.

TROY WEIGHT, in commerce. See the article WEIGHT.

TRUDE, in the art of war, denotes a suspension of arms, or a cessation of hostilities between two armies, in order to settle articles of peace, bury the dead, or the like.

TRUCHMAN, DRAGOMAN, or DROGMAN, in the countries of the Levant, signifies an interpreter. See DRAGOMAN.

TRUCKS; among gunners, round pieces of wood, fixed on the axle-trees of carriages; to move the ordnance at sea, and sometimes also at land.

TRUE, something agreeable to the reality of things, or to truth.

TRUE Place of a Planet or Star, in astronomy, is a point of the heavens, shewn or pointed out by a right line, drawn from the center of the earth, through the center of the planet or star. See PLANET, &c.

TRUFFLES, *Tubera terræ*, in natural history, a kind of subterraneous vegetable production, not unlike mushrooms, being a genus of fungi, which grows under the surface of the earth. See FUNGUS.

The truffle is only a fleshy tubercle, covered with a hard sort of crust, rough, and somewhat regularly furrowed on the surface, almost like the cyprus-nut. It does not rise above the surface of the earth, but lies concealed about half a foot below it. Great numbers of them are found in the same place, of different sizes: some of them are now and then found of a pound weight, or even a pound and a quarter; these last are but rare, and Pliny only mentions their being of a pound weight.

They grow at the feet and under the shades of trees, sometimes about the roots of stones, and sometimes in clear earth. Their favourite trees are either the white or green oak, as the elm is that of the morellæ. They begin to be found when warm weather first succeeds the cold, sooner or later, as the season is more or less mild; for they have sometimes been very rare after hard winters. At first they appear only like little round peas, red without, and white within. These peas grow larger by degrees; from that time they take out of the ground what they commonly call white truffles; these are of themselves insipid, and people dry them as an ingredient for ragouts, because they keep better when dried, than marbled ones do. It is a common opinion that truffles which have been once removed from their places, are never after capable of being nourished, even when put in some earth from which they were originally taken: but if one leave them there for a certain season, without disturbing them, they grow insensibly larger; their bark becomes black, rough, and unequal, though they always retain their whiteness within. Hitherto they have very little smell or taste, and can only be used in ragouts: these are always called the first white truffles, and are not to be made a different species from the marbled or black ones gathered in the end of autumn, and even in the winter after the frosts are begun.

When the truffles are at maturity, they have a very good smell and taste; and are fit to be dug from the month of October to the end of December; and sometimes to the end of February and March,

March, when they are even at that time marbled; whereas those gathered from the month of April till July and August, are only white.

If people neglect to gather the truffles when arrived at a due degree of maturity, they rot; and then we may observe the reproduction of the truffle; because, after some time, we see several bunches of other young truffles filling up the places of the rotten ones. These young truffles are nourished till the first colds come on; and if the frosts are not intense, they get over the winter, and furnish us sometimes with the fresh green truffles.

As to the virtues of truffles, the common opinion is, that they are hot; Galen, however, according to Matthiolus, looks upon them as indifferent, and the basis of all other seasoning; and, indeed, it is to this purpose that they are used in all ragouts. Avicenna speaks of them in a manner quite different, and says, they engender thick humours more than any other food; that they are hard of digestion, heavy on the stomach, and, when much used, have a tendency to bring on an apoplexy and palsy. These two authors may be reconciled, if we consider two qualities in the truffle, which are capable of producing two different effects: first, they may prove hot of themselves, by emitting their volatile salts into the stomach; or, by being mixed with salt, pepper, and other spices, which they drink up like a sponge: in the second place, they may prove of hard digestion, when eaten immoderately by a person of a weak stomach; in which case, they produce bad effects, stagnate, and form themselves into a glaucous substance, which disorders the stomach, and which may be occasioned by the cold quality ascribed to them by Galen. As a proof that the truffle is of hard digestion, it has this in common with other fruits, that it grows hard in spirit of wine, and is with difficulty dissolved in water.

**TRUMPET**, a musical instrument, the most noble of all portable ones of the wind kind, used chiefly in war, among the cavalry, to direct them in the service.

*Marine-TRUMPET*, is a musical instrument consisting of three tables, which form its triangular body.

It has a very long neck, with one single string, very thick, mounted on a bridge, which is firm on one side, but tremulous on the other. It is struck by a bow with one hand, and with the other the string is pressed, or stopped, on the neck by the thumb.

It is the trembling of the bridge, when struck, that makes it imitate the sound of a trumpet, which it does to that perfection, that it is scarce possible to distinguish the one from the other; and this is what has given it the denomination of marine-trumpet; though, in propriety, it is a kind of monochord.

*Harmonical-TRUMPET*, an instrument that imi-

tates the sound of a trumpet; which it resembles in every thing, excepting that it is longer, and consists of more branches; it is generally called sackbut.

*Speaking-TRUMPET*, is a tube from six to fifteen feet long, made of tin, perfectly straight, and with a very large aperture; the mouth-piece being big enough, to receive both lips.

**TRUMPET-FLOWER**, *Bignonia*, in botany. See **BIGNOMIA**.

**TRUMPET-SHELL**, the English name of the buccinum of authors. See **BUCCINUM**.

**TRUNCATED**, in general, is an appellation given to such things as have, or seem to have, their points cut off: thus we say, a truncated cone, pyramid, leaf, &c.

**TRUNDLE**, a sort of carriage with low wheels, whereon heavy and cumbersome burdens are drawn.

**TRUNK**, *Truncus*, among botanists, denotes the stem, or body of a tree; or that part between the ground and the place where it divides into branches.

In anatomy, trunk is used for the busto of a human body, exclusive of the head and limbs, comprehending the abdomen and thorax. See the articles **ABDOMEN** and **THORAX**.

**TRUNNIONS**, or **TRUNIONS** of a Piece of Ordnance, are those knobs or bunches of the gun's metal, which bear her up on the cheeks of the carriage: and hence the trunnion-ring is the ring about a cannon, next before the trunnions.

**TRUSS**, *Trussa*, a bundle, or certain quantity of hay, straw, &c.

A truss of hay is to contain fifty-six pounds, or half a hundred weight; thirty-six trusses make a load. In June and August the truss is to weigh sixty pounds, on forfeiture of eighteen shillings per truss.

**TRUSS**, is also used for a sort of bandage or ligature, made of steel, or the like matter, wherewith to keep up the parts, in those who have hernias or ruptures. See **HERNIA**.

**TRUSS of Flowers**, is used, by florists, to signify many flowers growing together on the head of a stalk, as in the cowslip, auricula, &c.

**TRUSS of Forage**, is as much as a trooper can carry on his horse's crupper.

**TRUSSES**, in a ship, are ropes made fast to the parrels of a yard, either to bind the yard to the mast when the ship rolls, or to hale down the yards in a storm, &c.

**TRUSSING**, in falconry, is a hawk's raising any fowl or prey aloft; first soaring up, and then descending with it to the ground.

**TRUST**, in law, signifies, in general, that confidence which one person reposes in another; and in case of non-performance, or breach of this trust, the remedy is by bill in equity, as the common law usually takes no notice of trusts.

**TRUSTEE**, one who has an estate, or money, put

put or trusted in his hands, for the use of another. Where two or more persons are appointed trustees, if one of them only receives all, or the greatest part, of the profits of the lands, &c. and is in arrears, and unable to satisfy the person to whom he is seised in trust, the other, in that case, shall not be answerable for more than comes to his hands.

**TRUTH**, *Veritas*, a term used in opposition to falsehood, and applied to propositions which answer or accord, to the nature and reality of the thing whereof something is affirmed or denied.

Truth, according to Mr. Locke, consists in the joining or separating of signs, as the things signified by them do agree or disagree one with another. Now the joining or separating of signs is what we call making of propositions. Truth then, properly, relates only to propositions, whereof there are two sorts, mental and verbal; as there are two sorts of signs commonly made use of, viz. ideas and words. See **IDEA** and **WORD**.

Mental propositions are those wherein the ideas in our understanding are put together, or separated, by the mind perceiving or judging of their agreement or disagreement.

Verbal propositions are words put together, or separated, in affirmative or negative sentences: so that a proposition consists in joining or separating of signs; and truth consists in putting together, or separating those signs, according as the things they stand for agree or disagree.

**Moral TRUTH**, consists in speaking things according to the persuasion of our minds, and is called also veracity.

**Metaphysical**, or **Transcendental TRUTH**, is nothing but the real existence of things conformable to the ideas which we have annexed to their names.

**TRY**, in the sea-language. A ship is said to try, or lie a-try, when no sails are abroad but the main-sail or mizzen-sail.

**TUB**, in commerce, denotes an indeterminate quantity or measure: thus, a tub of tea contains about sixty pounds; and a tub of camphor from fifty-six to eighty pounds.

**TUBE**, *Tubus*, in general, a pipe, conduit, or canal; a cylinder hollow within, either of lead, iron, wood, glass, or other matter, for the air, or some other fluid, to have a free passage, or conveyance, through. See the article **PIPE**.

Small silver or leaden tubes are frequently used, by surgeons, to draw off blood, matter, or water, from the different parts of the body.

*The Construction of a draw TUBE, for a Telescope.* The chief points to be regarded here are, that the tube be not troublesome by its weight, nor liable to warp and disturb the position of the glasses; so that every kind of tube will not serve in every case. See the article **TELESCOPE**.

1. If the tube be small, it is best made of thin

brass plates covered with tin, and formed into pipes or draws, to slide one within another.

2. For long tubes, iron would be too heavy, for which reason some chuse to make them of paper, thus: a wooden cylinder is turned, of the length of the paper to be used, and of a diameter equal to that of the smallest draw: about this cylinder is rolled paper till it be a sufficient thickness; when one pipe is dry, provide others after the same manner, still making the last serve for a mould to the next, till you have enough for the length of the tube desired. Lastly, to the extremes of the draws are to be glued wooden ferrils, that they may be drawn forth the better.

3. Since paper draws are apt to swell with moist weather, so as to spoil their sliding; and in dry weather to shrink, which renders them loose and tottering; in both which cases the situation of the lens is easily disturbed; the best method of making of tubes is as follows: Glue parchment round a wooden cylinder, and let the parchment be coloured black, to prevent the reflecting rays making any confusion: provide very thin slits of beech, and bending them into a cylinder, glue them carefully to the parchment; cover this wooden case with white parchment, and, about its outer extreme, make a little ring or ferril: after the same manner, make another draw over the former, and then another, till you have enough for the length of the tube.

To the inner extremes of each draw fit a wooden ferril, that the spurious rays, striking against the sides, may be intercepted and lost. In these places where the lenses are to be put, it will be proper to furnish the ferrils with female screws. Provide a wooden cover to defend the object-glass from the dust; and, putting the eye-glass in its wooden ferril, fasten it by the screw to the tube. Lastly, provide a little wooden tube of a length equal to the distance the eye-glass is to be from the eye, and fit it to the other extreme of the tube.

**TUBER**, or **TUBERCLE**, in botany, a kind of round turgid root, in form of a knob or turnip.

The plants which produce such roots are hence denominated tuberose, or tuberous, plants.

**TUBER**, or **TUBEROSITY**, in medicine, is used for a knob, or tumour, growing naturally in any part; in opposition to tumours, which arise accidentally, or from disease.

**TUBERCLES**, among physicians, denote little tumours which suppurate and discharge pus, and are often found in the lungs, especially of consumptive persons. See the articles **CONSUMPTION** and **PHTHISIS**.

**TUBEROSE**, polianthos, in botany, a bulbous rooted plant, much admired for the fragrant of its blossoms, which are produced in spikes on the upper part of a stem which rises four or five feet high; each

each flower consists of a monopetalous funnel-shaped corolla, the tube of which is incurved, oblong, and divided into six ovate patent segments; the stamina are six thick obtuse filaments, topped with linear antheræ: the fruit is an obtuse, three cornered, roundish capsule, having three valves and three cells, which contain a number of plane semi-orbiculated seeds.

The tuberoſe root ſhould be planted in pots in March, and plunged in a moderate hot-bed, and as they advance in growth ſhould have a good ſhare of air and neceſſary watering until they have arrived to their perfection, which will be in July and Auguſt, when they may be planted where moſt agreeable for their fine perfume, which is ſuſceptible at a conſiderable diſtance in a confined place.

**TUBEROSE ROOTS**, among botaniſts, are thoſe which are compoſed of many ſeſhy tubercles; and either ſit cloſe to the ſtalk, as thoſe of the garden ranunculus, or are ſuſpended by fibres or threads, ſuch are thoſe of the potatoe, Jeruſalem artichoke, peony, &c.

**TUBIPORA**, or **TUBULARIA**, a genus of ſubmarine plants, belonging to the cryptogamia claſs, of the hardneſs of coral, and conſiſting of cylindric tubes riſing from a thin cruſt of the ſame ſort of matter with themſelves.

**TUBULARIA FOSSILIS**, in natural hiſtory, the name of a ſpecies of coral found very often foſſil in Germany and Italy, and compoſed of a great number of tubes, or longitudinal pipes, often reſembling ſo many worms ranged perpendicularly in the maſs.

**TUBULI FOSSILIS**, in natural hiſtory, the tubules, or caſes of ſea-worms, found buried in the earth.

**TUBULI LACTIFERI**, in anatomy, the ſmall tubes, or veſſels, through which the milk flows to the nipples of womens breſts. See the article **MILK**.

**TUCK** of a Ship, the truſſing or gathering up the quarter under water; which if ſhe lie deep, makes her have a broad, or, as they call it, fat quarter, and hinders her ſteering, by keeping the water from paſſing ſwiftly to her rudder; and if this truſſing lie too high above the water, ſhe will want bearing for her works behind; unleſs her quarter be very well laid out.

**TULIP**, *Tulipa*, in botany, a genus of plants, whoſe flower is bell-shaped, and compoſed of fix ovato-oblong, concave, erect petals; the ſtamina are fix ſubulated filaments, topped with oblong erect quadrangular antheræ: the germen is oblong, taper, and three-cornered: it hath no ſtyle, but is crowned with a triangular, three-lobed, perſiſtent ſtigma: the fruit is a triquetrous and trilocular capsule, containing a great many flat ſeeds, ranged over each other in a double order.

The tulip-root is bulbous, from which ariſes the ſtem, from a foot to two feet high, adorned at the

baſe with a few pointed leaves, of a pale green colour; on the extremity of the ſtalk the flower is produced, which is much admired for the beauty of its fine ſtripes and rich colours.

This flower is probably a native of Turkey, of which the name is a proof, being derived from the Turkiſh word *tulpent*, which ſignifies a cap or turban; but though it be originally from that country, Holland is the great magazine of the fineſt and moſt curious tulips, which are raiſed there by the diligence of the ſloriſts of the low countries.

In Holland they reckon four principal ſorts; 1. the early or ſpring-tulips; 2. the double-flowered tulips; 3. the late expectant tulips; 4. the late ſtriped tulips, with a yellow or white bottom.

The ſpring-tulips were formerly held in ſo great reputation in Holland, that the ſloriſts placed their higheſt ambition in the poſſeſſion of them. This paſſion roſe to that extravagance, from the year 1634 to 1637, that ſingle roots were ſold from 2000 to 5500 guilders; this madneſs was at laſt checked by the interpoſition of the ſtates of Holland and Weſt Frieſland, April 27, 1637; ſince that time the late-blowers have gained the preference, and the ſpring tulips are no longer in ſuch high eſtimation: however, they are not to be caſt away, as ſome of them blow, in mild ſeaſons, ſo early as February, and are very pretty, particularly a ſort called the Duke Van-Tol; their principal beauty conſiſts in their cupping well, their bright and gay colours, and being well broke. There are ſome that have their leaves prettily and lightly variegated with yellow and green, for which they are the more valuable.

When the ſpring flowers are gone off, the double tulips ſucceed; theſe are large flowers, well filled with petals, and ſtanding a foot and a half or two feet high, of a very agreeable white, variegated with a bright lively red, making a delightful ſhew at a diſtance, and the variety of their forms and colours ſtrikes the eye very agreeably.

The late expectant tulips, as the Dutch call them, from the expectation they have of raiſing fine new flowers from them; they alſo call them tulips of one colour, or whole blowers: we, in England, call them breeding tulips, becauſe from them the moſt admired new flowers are produced; in Germany they have the name of mother tulips, becauſe we have nothing fine in the tulip kind but what owes its birth to them. They are not very beautiful in themſelves, but are very valuable for the reaſons above-mentioned, and a good ſloriſt ſhould never be without a conſiderable number of them in his garden, from which he may breed very fine tulips, a thing he muſt never hope to accompliſh but by their means, for theſe answer the ſame purpoſe in raiſing curious new tulips, as the ſeed does in hyacinths.

Many ſtrange whims have been praſtiſed in order to

to produce the variety of colours in the breeding tulips; some have been led by their capricious folly to cut two roots through the heart, and to imagine that they should accomplish their desire by joining the parts of the different roots together, not considering that the dividing a root in that manner was robbing it of life; but we shall pass over these useless chimeras, and shew two very easy and simple methods of producing this marvelous alteration: The first is to set the bulbs of the breeders in a very poor soil; and this practice is built on a well-grounded hypothesis, which has ever prevailed, and is still maintained, that the breaking of flowers is occasioned by the weakening of their natural strength, and no cause is better adapted to produce this effect than the defect of nutriment. The second method is to make as great a change as possible in the soil the bulbs are to be set in, either by taking them out of one garden and planting them in another, or by mixing different kinds of earth, or by procuring new sorts every year from Holland; as we have often experienced so great a change of air and soil causes a great variety of colours: but we do not positively assert that these methods will always succeed, because nature will not at all times second our endeavours; it is, however, most certain, that there are no better methods known than those above-mentioned.

The variegated late blowers are the last sort of tulips that deserve notice; these are, beyond dispute, the most diversified, beautiful, and perfect of all: there is an almost infinite number of varieties, all arising originally from one distinct species, which are reduced by florists into five classes: 1. tulips with a white bottom, striped with brown, called *baguette primo*; 2. such as have a white bottom, striped with brown, called *baguette rigaut*; 3. those with a white bottom, striped with violet and blackish-brown, called *biblioemen*; 4. those with a white bottom, striped with rose colour, vermilion, and ruby; 5. such as have a yellow bottom, striped with different colours, called *bizarres*.

The properties required in a fine tulip, are, 1. that it should have a tall stem, rising to the height of three or four feet, because this is agreeable to the nature of the tulip; all florists, indeed, do not concur in this opinion, for in some places the height of the tulip is not regarded, whereas in England, Holland; and Flanders, a tulip with a short stem is but little esteemed.

2. That the corolla be large, well proportioned, and composed of six petals, three within and three without; these should not be too long nor pointed, because that would spoil their symmetry, which frequently occurs in old tulips, and sometimes in modern ones; these petals when opened should neither turn inward nor bend outward, for if they turn in, much of their beauty is diminished, yet there are many fine tulips which labour under this defect;

the petals ought also to be round at their extremities, broad, and thick, for when they are thin they crumple, and the colours are apt to be blended.

3. The colours ought to be lively and bright; those that are most valued and held in greatest esteem, are, the black, golden-yellow, purple-violet, rose, and vermilion colours. Tulips whose flowers are finely striped, and variegated with three colours, distinct and unmixed, with very strong and regular streaks, without any tinge of the colour of the breeder, are the finest *bizarres*, and may be called perfect tulips.

It would also be a perfection in tulips if the colours always came out the same, but this is not the case, it happening sometimes that a flower of very great price, degenerates and becomes of no value, and there is no known method to prevent this metamorphosis, for which nature alone is answerable. All tulips are not equally liable to this alteration of colour, some being less susceptible of it than others, as the *baguette primo* and the *baguette rigaut*, which are the least subject to it of any: those that have a white bottom with a very fine shade, as also the *bizarres*, whose fine diversified colours form a kind of beard at the extremities of the petals, are not very changeable; but the true *bizarres*, that are painted with a mixture of several colours, and tinged with that of the breeder, have their beauty soon obliterated by a sudden change.

Tulips are increased either from off-sets or seeds; the season for planting the off-sets and blowing-roots is in October or November; they may also be planted in January or February, where the soil is very moist.

The most curious in flowers set them in beds at six, seven, or eight inches asunder, according to the sorts, and at the depth of six or seven inches: when they begin to appear above ground, in the spring, bad weather and frosts may much injure the tender leaves, and thereby do great damage to the flowers; therefore, at those times, they should be carefully sheltered with mats, &c. for if this be neglected, the stems and leaves will suffer by it; nor will the mischief end there, but will be extended both to the flowers, which will be less beautiful, and also to the roots, which will be weakened and very much affected by the loss of the leaves.

When the stems grow up and the flowers begin to colour, they ought to be supported, otherwise the wind would break them down; for this purpose, sticks should be prepared of a proportional length and thickness, to which the stems should be fastened.

The tulips, when in bloom, should be shaded from the violence of the meridian sun, otherwise they will be but of short duration.

The time for taking up the roots is usually in June, when the leaves are withered; they should then be laid in an airy place, but not exposed to the

the sun; and three or four weeks afterward, when they are well dried, they should be freed from their outward skins, and then laid in the same place, where they may remain until the time of planting.

There are few but the Hollanders who have the patience to raise tulips from seeds, as we must wait eight or ten years before we can see a tulip in flower, that has been produced from seed, and after all it is but a whole-blower. Such, however, as like to sow, may chuse such sorts of tulips as please them best; the most curious, indeed, are for the breeders, but we leave every one to his own choice.

When the florist has fixed upon the flowers he would save seed from, he must let them have the benefit of the sun and air, otherwise the seeds will not come to perfection; they must be suffered to stand in the ground till the seed-vessels begin to open and shew the seeds of a brown colour; they must then be cut and laid in a dry place, letting the seeds remain in their capsules till the month of September: the seeds are then to be sown at the depth of an inch, in pots filled with well prepared earth, which must be placed in the shade till November, when they may be exposed to the sun. In the spring they are to be set again in the shade, and afterwards watered while the leaves are green; but when the leaves are withered, the roots are to be taken out of these pots and put into others, which are to be exposed to the sun in the same manner as the former year: after two years, the bulbs are to be taken out of these second pots and treated like other tulips.

**TULIP-TREE**, *Liriodendrum*, in botany, a plant which grows naturally in many parts of North America, where it arrives to a tree of the first magnitude; the young branches are covered with a smooth purplish bark, and furnished with large leaves, whose footstalks are four inches long and ranged alternately; the leaves are of a singular form, being divided into three lobes, the middle one is blunt and hollowed, appearing as if a piece was cut out; the two side lobes are rounded, and end in blunt points; the upper surface of the leaves is smooth and of a lucid green, and the under is of a pale green; the flowers are produced at the extremities of the branches, they are each composed of six petals, three without and three within, forming a sort of bell-shaped flower, much resembling the tulip (whence the name) these petals are marked with green, yellow, and red spots, making a fine appearance when the tree is full of flowers; the stamina consists of many filaments, with linear antheræ fastened to their sides; the germina are numerous, and when the petals drop, they swell and form a kind of cone, consisting of many imbricated compressed seeds: the flowers come out in July.

This tree is propagated from seeds sown in the spring on a hot bed, and afterwards hardened by degrees to the sun and air.

**Chequered TULIP**, *Fritillaria*, in botany, a genus of plants, whose flower is hexapetalous and campanulated, with a nectarium placed in the base of each petal; the stamina are six subulated filaments, terminated with oblong, erect, quadrangular antheræ; the fruit is an oblong, obtuse, trilobular capsule, with three cells containing many flat seeds ranged in a double order.

To this genus Linnæus has added the *corona imperialis* of Tournefort.

**TUMEFACATION**, the act of swelling or rising into a tumour. See the next article.

**TUMOUR**, or **TUMOR**, in medicine and surgery, a preternatural rising or eminence on any part of the body. Tumour is also defined, by physicians, a solution of continuity arising from some humour collected in a certain part of the body, which disjoins the continuous parts, insinuates itself between them, and destroys their proper form.

Whether there be any such preternatural rising or enlargement on any part of the body, may be discovered from inspection, but more particularly by feeling. And, notwithstanding, it is a general custom to refer excrescences, as warts, corns, and such as grow in the nose and pudenda, to the class of tumours; yet, because they grow not from beneath, but out of, or upon, the skin itself, it is thought proper not to comprehend them in the general division of tumours.

There are tumours of various kinds, distinguished by particular names, according to the different causes from whence they proceed, and the particular parts wherein they are seated; some are called hot, others cold and watry; some are termed windy, others schirrhous; and some are named benign, others malignant: but Heister finds fault with these distinctions. There are some tumours which being contained in a proper membrane, are therefore called cystic; and if this should be in an artery, it is usually termed aneurism; but when in a vein, a varix. When in the veins of the anus, or rectum, the disorder is termed hæmorrhoids; but if the tumour be in the scrotum, unguen, or at the umbilicus, it is called a hernia: if any pus, or matter, is contained in the tumour, it is called an abscess; and if the tumour is seated in the bone, it is termed exostosis.

The forementioned class of tumours are all of them subdivided into several other kinds: thus the hot and burning tumours, which are the same with inflammations, are generally termed phlegmons when violent and seated in the common integuments; but when slighter, they are commonly called feruncles. The inflammation which is not fixed deep, but spreads only superficially upon the skin, is termed an erysipelas: the inflammatory tumour that arises at the finger-ends is termed paronychia: that which fixes in the groin or armpits is called a bubo; and that under the ears a parotis. When an inflammation

tion seizes the hands and feet from extreme cold, chilblains arise; which tumour is called *pernio*.

*Encysted Tumours*, tumours arising in different parts of the body, but contained in certain membranous coats: these are sometimes harder, sometimes softer, of a palish colour, and usually attended with little pain. These tumours arise from obstructions either in the glands, or in the adipose membrane, more especially about the face and neck, where they occasion great deformity. The membranous coat with which these tumours are invested, is often of a considerable thickness, and is usually the coat of the disordered gland, or some of the adipose cells. At their beginning they are usually very small and moveable; but encreasing by slow degrees, they grow sometimes to an enormous bulk.

The consistence of some of these tumours is soft and fluctuating, and of others more hard and firm. They are of all shapes and sizes, and some of them become hard as a callus, and unmoveable, while others are, for the generality, soft and moveable.

They are distinguished according to the consistence of their contents; some are called *atheromata*, from their contents resembling paste; others, which have them of the consistence of honey, are called *meliceræ*; but if they are of a fatty substance, like suet or lard, they are called *steatomata*. If they happen in a gland which becomes indurated, they are called *schirrous*: and lastly, when they are of a fleshy consistence, they are called *sarcomata*. Some of these tumours have been found also full of hair.

They are distinguished by others according to the places where they are situated. Those seated under the scalp are called *talpa*, *testudo*, or *lupia*. Those in the neck, *strumæ* or *scrophulæ*; and those in the hands and feet, especially if among the tendons, are called *ganglions*.

There is no general method for the cure of them; but the surgeon, according to their different circumstances, attempts this by discussion, suppuration, or extirpation.

But if the tumour can neither be dispersed nor suppurated, but continues to enlarge itself, it is advisable to extirpate it, in order to prevent its turning into a cancerous nature. There are several methods in practice for extirpating these tumours according to their nature and size: those which are small and hard, or hung by a root as by a stalk, are generally best removed by ligature, in the manner of warts; by which means they wither and fall off of themselves in a few days. But the most ready and expeditious method is to cut them off with a scalpel, and then heal up the wound: but if in removing them this way you divide a considerable artery, you may stop it by some potential, or even the actual cautery; or else, by taking it up with a needle and thread. Lastly, these tumours may be often removed by the application of caustic or corroding medicines, retained about the root by means of plasters, com-

presses, and a bandage; and when you find the root of the tumour almost corroded through, the rest may be divided by the scalpel. See the article *CAUSTIC*.

If the root of the encysted tumour appears too large for it to be conveniently taken off by ligature, you must then remove it either by the knife or by the caustics, though the latter is generally preferred. In order to extirpate it by the knife, you must first make a longitudinal incision upon the tumour; and if that does not appear sufficient, make another incision across the former, till you think the wound large enough for taking out the tumour; in order to which you next dilate the integuments, and separate them from the cyst of the tumour, which you are to take out whole, if possible, either by means of the scalpel, a hook, or by passing a crooked needle, with a strong thread, crosswise under the tumour; but great caution is necessary in this operation, lest any important part that is contiguous to the tumour be injured.

The tumour being thus carefully extracted, if the wound and hæmorrhage be small, you may press the lips together; and by covering the same with lint and compresses, retained with a proper bandage, the patient is cured in a few days time; but in case of a profuse hæmorrhage, the blood is to be stopped either by ligature, astringents, or the actual or potential cautery.

*TUN*, or *TON*, originally signifies a large vessel or cask of an oblong form, biggest in the middle, and diminishing towards its two ends, girt about with hoops, and used for stowing several kinds of merchandize, for convenience of carriage; as brandy, oil, sugar, skins, hats, &c.

This word is also used for certain vessels of extraordinary bigness, serving to keep wine in for several years.

*TUN* is also a certain measure for liquids; as wine, oil, &c. See *MEASURE*.

*TUN* is also a certain weight whereby the burden of ships, &c. are estimated. See *WEIGHT*.

*TUNA*, in botany, the same with the *cactus*. See the article *CACTUS*.

*TUNE*, or *TONE*, in music, that property of sounds whereby they come under the relation of acute and grave to one another.

Though gravity and acuteness are mere terms of relation, the tune of the sound is something absolute, every sound having its own proper tone, which must be under some determinate measure in the nature of the thing.

The only difference then, between one tune and another is in the degrees.

If two or more sounds be compared together in this relation, they are either equal or unequal in the degree of tune.

Such as are equal are called *unisons*.

The unequal constitute what we call an *interval*, which is the difference of time between two sounds.

Sonorous bodies we find differ in tune: 1. According to the different kinds of matter; thus a wedge of silver sounds much more acute than a wedge of gold of the same shape and dimensions; in which case the tones are proportional to the specific gravity. 2. According to the different quantities of the same matter in bodies of the same figure, a solid sphere of brass, one foot diameter, sounds acuter than one of two feet diameter; in which case the tunes are proportional to the quantity of matter. Here then are different tunes connected with different specific gravities and quantities of matter, as their immediate cause. In effect, the measures of tune are only sought in the relations of the motions that are the cause of sound, which are no way so discernable as in vibrations of chords.

In the general we find that, in two chords, all things being equal, except tension, or thickness, or length, the tunes are different; there must, therefore, be a difference in the vibrations owing to these different tensions, &c. which difference can only be in the velocity of the courses and recourses of the chords, through the spaces wherein they move to and again. Now, upon examining the proportion of the velocity and the things just mentioned, wherein it depends, it is found, to a demonstration, that all the vibrations of the same chord are performed in equal times. Hence, as the tone of a sound depends on the nature of those vibrations, whose difference we can conceive no otherwise than as having different velocities; and as the small vibrations of the same chord are performed in equal times, and it is found true, in fact, that the sound of any body, arising from any individual stroke, though it grows gradually weaker, yet continues the same tone from first to last: it follows, that the tone is necessarily connected with a certain quantity of time, in making every single vibration; or, that a certain number of vibrations, accomplished in a given time, constitutes a certain determinate tune; for the more frequent those vibrations are, the more acute the tone; and, the slower and fewer they are, the more grave the sound, though performed in the same space of time; so that any given note of a tune is made by one certain measure of velocity of vibrations, i. e. such certain courses and recourses of a chord or string, in such a certain space of time, constitute a determinate tune.

This theory is strongly supported by our best and latest writers on music, Dr. Holder, Mr. Malcolm, &c. both from reason and experience. Dr. Wallis, who holds it very reasonable, adds that it is evident the degrees of acuteness are reciprocally as the lengths of the chords, though, he says, he will not positively affirm that the degrees of acuteness answer the number of vibrations as their true cause: but this difference arises hence, that he doubts whether the thing has been sufficiently proved by experiment. Indeed, whether the different num-

ber of vibrations, in a given time, is the true cause on the part of the object of our perceiving a difference of tune, is a thing which, we conceive, does not come within the reach of experiment. It is enough that the hypothesis is reasonable.

**TUNICA**, *Tunic*, in anatomy, is applied to the membranes which invest the vessels, and divers others of the less solid parts of the body; thus the intestines are formed of five tunics, or coats.

There are also five tunics, or coats, of the eye, for which see the article **EYE**.

**TUNNAGE** is used for a custom or impost, payable to the crown, for goods and merchandize imported or exported, and is to be paid after a certain rate for every tun thereof. This duty, as well as that of poundage, was first granted for life to king Charles II. and has been continued in the same manner to his royal successors, down to his present majesty George III.

**TUNNEL-NET**, a net for taking partridges, which should not exceed fifteen feet in length, nor be less than eighteen inches in breadth, or opening for the entrance.

**TUNNING of Ale or Beer**, a part of the process of brewing, or rather an operation which is the sequel thereof. When the beer has worked or fermented in an open vat, as long as is proper, tun it up into seasoned vessels, that is, such as have had ale or beer in them before; for if it be put into new casks, it must be made stronger than ordinary, else it will not keep so long, because the cask will imbibe the spirits, and the rest will soon become flat and vapid. It is best to tun beer just when it comes to a due fermentation, and gets a good head; for then it has the most strength to clear itself in the cask, and what works over may be put into the small beer, and must be supplied with fresh beer of the same brewing. When the beer is tunned, carry it while it works in the cask, into a good cellar, or proper place to preserve it; for if it be stirred after it has done working, it will be apt to grow stale, sour, and become aleger.

**TUPELO-TREE**, in botany. See the article **NYSSA**.

**TURBARY**, denotes a right to dig turfs on another's ground; and it is likewise taken for the ground or place where turfs are digged, sometimes called the turfary.

**TURBINATED**, is a term applied by naturalists to shells, which are spiral, or wreathed, conically, from a larger basis to a kind of apex.

**TURBITH**, or **TURPETH-ROOT**, in the materia medica, the cortical part of the root of an Indian convulvulus, brought to us in oblong pieces, of a brown or ash-colour on the outside, and whitish within: the best is pendorous, not wrinkled, easy to break, and discovering a large quantity of resinous matter to the eye: its taste is at first sweetish; when chewed for a little time, it becomes acid

acid, pungent, and nauseous. This root is a cathartic, not of the safest, or most certain kind: the resinous matter in which its virtue resides, appears to be very unequally distributed, insomuch that some pieces, taken from a scruple to a dram, purge violently; whilst others, in larger doses, have scarce any effect at all. An extract made from the root, is more uniform in strength, though not superior, or even equal, to purgatives more common in the shops.

**TURBITH MINERAL**, a name given by chemists to a yellow precipitate of mercury, prepared after the following manner. Upon purified quicksilver, contained in a glass vessel, pour double its weight of the strong spirit or oil of vitriol. Heat the liquor by degrees, so as at length to make it boil, till a white mass remains, which is to be thoroughly dried, with a strong fire. This mass, on the effusion of warm water, grows yellowish and falls into powder; which is to be carefully ground with the water in a glass mortar: then suffer it to settle, pour off the water, and wash the powder in several parcels of fresh water, until it is sufficiently dulcified.

This preparation is a strong emetic, and operates the most powerfully of all the mercurials that can be safely given internally. Its action, however, is not confined to the primæ viæ; it will sometimes excite a ptyalism, if a purgative is not soon taken after it. It is used chiefly in violent gonorrhæas, and other venereal cases, where there is a great flux of humours to the parts: the dose is from two grains, to six or eight; though there are some constitutions, which have been used to mercurials, that bear well even the dose of a scruple. This medicine has also of late been recommended as the most effectual preservative against the hydrophobia.

The washings of turbith mineral are by some externally applied for the itch, and other cutaneous foulnesses; but in these cases, though it often does service, the patient must not be too free with it.

**TURBOT**, or **TURBUT**, in ichthyology, the English name of a species of pleuronectes, with the eyes on the right side, and the body smooth.

It grows to a considerable size, and is one of the most esteemed fish at table.

**TURCICA TERRA**, Turkey earth, in the materia medica, a very fine bole or medicinal earth, dug in great plenty in the neighbourhood of Adrianople, and used by the Turks as a sudorific and astringent; and famous among them in pestilential diseases. It is sometimes brought over to us also made up into flattish, orbicular masses of two or three drams weight, and sealed with some Turkish characters. This earth is of a somewhat lax and friable texture, yet considerably heavy, of a greyish, red colour, but always redder on the surface than within; extremely soft, and naturally of a smooth

surface: it melts freely in the mouth, with a considerably strong, astringent taste.

**TURCOISE**, or **TURQUOISE**, *Turquesia*, in natural history, an ore of copper, erroneously ranked among gems.

There are, indeed, two kinds of turquoise; the one a true and genuine ore of copper; the other, the bones of animals tinged to a beautiful blue colour, by having been buried in places where copper-ore has been near them.

That kind which we usually distinguish by the name of the turquoise of the old rock, and which Pliny and the ancients called callais, is a true and genuine copper-ore, and is of exactly that kind in regard to this metal, that the hæmatites is to iron; it is found in the perpendicular fissures of the strata of stone, which contain copper adhering to their sides in form of a crust, and rising into botryoides efflorescences, which sometimes stand single, and are in bigness from the size of a pea to that of a walnut; but sometimes happening to be placed close to one another, they join and form flat crusts or masses, extending, in the manner of crusts of the hæmatites, to three, four, or more inches in breadth; in these the prominent part of every tubercle appearing on the surface, the whole seems a conjunction of semi-circular bodies of a fine blue colour joined by an intermediate substance of the same nature.

This kind of the turquoise is of a very close texture and glossy surface, but very soft, and, when broken, shews the same crustated and striated texture with the hæmatites; only that the striæ are usually finer, and the plates better joined. It ferments with aqua-fortis, and may be in great part dissolved by it; and on calcining, it loses all its colour, and becomes of a dirty white. This is produced in Persia, and some other parts of the East. The Germans also have a botryoides copper-ore, in some of their mines; but it is green and much softer than the true turquoise of this kind, though this has been often produced among us also under the name of that gem.

The other turquoise is nothing more than the teeth or bones of animals, which have lain in the way of effluvia in which copper has been contained, and by this means have acquired veins and streaks of a deep blue, which, on the whole being slightly calcined, diffuse themselves through all the substance, and give the fine pale blue we so much admire in this gem. If the fire that diffuses this colour be a little too strong, it sends it wholly off, and leaves in place of the turquoise only a white bone.

The turquoises of this last kind are common in France; there are mines of them there, and the people who work them are perfectly acquainted with the method of diffusing the colour through them. These are what are now usually worn, and, when fine, are called, by many of our jewellers,

jewellers, turquoises of the old rock, as well as the other.

The virtues attributed to this gem are very great, but all we know of it at present is, that, like the other bodies that contain copper, it is a violent emetic, and not fit to be received into practice.

**TURGESCENCE**, or **TURGESCENCY**, among physicians, denotes a swelling, or growing bloated.

**TURIONES**, among herbalists, denotes the first young tender shoots, which plants annually put forth.

**TURKEY**, *Meleagris*, in ornithology, a genus of birds, the anterior part of the head of which is covered with a fleshy pendulous substance; the sides of the head also, and the throat, are covered with a papillous fleshy matter, and there is a longitudinal fleshy crest, of a reddish, bluish, or purplish colour, and a soft substance. There is but one known species of this genus.

**TURKY-EARTH**. See **TURCICA-TERRA**.

**TURMERIC**, in the materia medica, the root of a plant, called by botanists, curcuma. See the article **CURCUMA**.

It is a small root, of an oblong figure, usually met with in pieces from half an inch to an inch or two in length, and at the utmost surface the thickness of a man's little finger; its surface is uneven, and rises into knobs in many places, and the longer pieces are seldom very straight; it is very heavy and hard to break; it is not easily cut through with a knife, but, when cut, leaves a glossy surface.

Its colour, externally, is a pale whitish grey, with some faint tinge of yellowness, and when broken, is of a fine yellow within; this colour is bright and pale, and without admixture, when the root is fresh; but in keeping, it by degrees becomes reddish, and at length is much like saffron in the cake. Thrown into water, it speedily gives it a fine yellow tinge; and, chewed in the mouth, it gives the spittle the same colour. It is easily powdered in the mortar, and according to its different age, makes a yellow, an orange-colour, or a reddish powder.

It has a kind of aromatic smell, with something of the odour of ginger in it. The taste is acrid and disagreeable, and has a considerable bitterness.

It is brought from the East-Indies, where they use it in sauces and foods.

As a medicine, it is esteemed aperient and emmenagogue, and of singular efficacy in the jaundice. But besides these uses, the glovers use it for dyeing their leather; and the turners, to give an agreeable yellow to several of their works made in the whiter woods.

**TURN**, in law, a court held twice a year, viz. within a month after Easter and Michaelmas, respectively, by the sheriff of every county.

**TURNADO**, or **TORNADO**, a wind which on some coasts blows all night from the shore.

**TURNAMENT**, or **TOURNAMENT**, a martial sport, or exercise, which the ancient cavaliers used to perform to shew their bravery and address.

**TURNEP**, *Rapa*, in botany, a genus of plants, whose flower consists of four yellow petals, disposed in the form of a cross, and six erect subulated filaments, two of which are shorter than the others, and topped with erect acute-pointed antheræ: the fruit is a long taper pod, depressed on the sides, having two cells which contain a number of round seeds.

The turnep-plant is so universally known, that a particular description of it is not necessary: it is classed by Linnæus among the brassicas, or cabages.

There are several sorts of turneps, as the round red or purple-topped turnep, the green-topped turnep, the yellow turnep, the black-rooted turnep, the early Dutch turnep, the French turnep, &c. which are all propagated by sowing their seeds.

The green-topped turnep is most esteemed by the farmers, as the root grows above ground more than the other sorts, which renders it preferable for feeding cattle; and being the softest and sweetest root, when grown large, of any of the kinds, is therefore most valued for the table.

All the sorts of turneps delight in a light sandy soil, not over rich; for in a soil which has been used to be manured, they are apt to grow rank and sticky.

The common season among the farmers, for sowing turneps, is July; sometimes in June and August, but not later. In Norfolk and some other counties, they cultivate great quantities of turneps for feeding black cattle, which turn to great advantage to their lands, for hereby they procure a good dressing; so that they have extraordinary good crops of barley upon those lands, which would not have been worth the ploughing, if it had not been thus husbanded.

When the turneps are to be fed off the ground, the cattle should not be suffered to run over too much at a time; for if they are not confined with hurdles, to as much as is sufficient for them one day, the cattle will spoil three times the quantity of turneps they can eat; so that it is very bad husbandry to give them too much room: therefore the hurdles should be removed forward once or twice every day. If the turneps are drawn out of the ground before the cattle, or sheep, are turned into the new inclosure, there will be no waste made; for they will then eat up the whole roots; whereas if they are turned upon the turneps growing, they will scoop the roots and leave the rinds, which being hollow, the urine of the sheep will be lodged in them; so that when they are forked out of the ground, the sheep will not eat any one of those which are thus tainted.

The

The Dutch turnep is commonly sown in the spring for culinary purposes, before the other sorts come in. This is the best kind of turnep for summer use; but the land where they are sown should be of a moist nature, otherwise they soon become stringy, and very rank, so as to be unfit for use.

In order to save good turnep seeds, some of the fairest roots should be chosen in February, and planted in rows, about eighteen inches or two feet asunder; and when their pods are formed, they should be carefully guarded from the birds, otherwise they will soon devour the seeds, especially when near ripe. When the seeds are ripe, the stems should be cut, and spread to dry in the sun; after which they may be threshed out and preserved for use.

Turneps are much better known in food than in medicine; they are certainly very cooling and cleansing, and agreeably absterge the viscid and mucous adhesions which often nauseate the stomach and disorder the first passages; they afford a very innocent and light nourishment to constitutions extremely weakened; and the liquor pressed out of them, when boiled, is accounted good in hectic, tartarous obstructions, and tubercles of the lungs, in which intensions Crato much commends them; and because this liquor is manifestly diuretic, it is used to keep open and cleanse the kidneys and their appendages. Turnep-juice is also said to be good in asthma, by taking a large spoonful in a morning fasting, for forty days together. Turneps are a wonderful pleasant sauce to the great quantities of flesh we eat; for they help to attenuate and divide those parts which otherwise would make the juice of too tough and gross a consistence to pass readily through the vessels in circulation.

TURNERA, in botany, a genus of plants, whose flower consists of five plane, pointed, obversely-cordated petals, with narrow unguis inserted in the tube of the cup: the stamina are five subulated filaments, topped with erect acuminate antheræ: the fruit is an ovate capsule, having three valves and one cell, which contains a number of oblong obtuse seeds.

TURNING, a branch of sculpture, being the art of fashioning hard bodies, as brass, ivory, wood, &c. into a round or oval form, in a lathe.

Turning is performed by putting the substance to be turned upon two points as an axis, and moving it round on that axis; while an edge-tool, set steady to the outside of the substance in the circumvolution thereof, cuts off all the parts which lie farther off the axis, and makes the outside of that substance concentric to the axis. See LATHE.

The invention of turning seems to have been very ancient. Some, indeed, to do honour to the age, will have it brought to perfection by the moderns; but, if what Pliny and some other ancient authors relate, be true, that the ancients turned

those precious vases enriched with figures and ornaments in relievo, which we still see in the cabinets of the curious, it must be owned that all that has been added in these ages, makes but poor amends for what we lost of the manner of turning of the ancients.

TURNING-EVIL, in cattle, a disease that causes them frequently to turn round in the same place. It is also called the sturdy.

The common remedy, recommended by Mr. Markham, is to throw the beast down, and bind him; then to open his skull, and take out a little bladder, filled with water and blood, which usually lies near the membrane of the brain, and then gradually heal the wound.

TURNPIKE, a gate set up across a road, watched by an officer for the purpose, in order to stop travellers, waggons, coaches, &c. to take toll of them, towards repairing or keeping the roads in repair.

In case any person shall drive horses or other cattle thro' grounds adjoining to the high ways, thereby to avoid the toll, they are liable to forfeit 10s. Or if any one assaults a collector of the tolls, or by force passes through a turnpike-gate without paying, he forfeits 5*l.* leviable by justices of peace; and maliciously pulling down a turnpike is deemed felony.

TURNPIKE, is also used, in the military art, for a beam struck full of spikes, to be placed in a gap, a breach, or at the entrance of a camp, to keep off an enemy. See CHEVAUX *de Frise*.

TURNSOLE, *Heliotropium*, in botany. See HELIOTROPIUM.

TURPENTINE, a transparent sort of resin, flowing either naturally or by incision from several unctuous and resinous trees, as the terebinthus, fir, pine, larch, &c.

We distinguish several kinds of turpentine; as that of Chio, of Venice, of Bourdeaux, of Cyprus, Strasburg, &c.

The turpentine of Chio, or Scio, which is the only genuine kind, and that which gives the denomination to all the rest, is a whitish resin, bordering a little on green, very clear, and a little odorous; drawn by incision from a tree called terebinthus, very common in that island, as also in Cyprus, and some parts of France and Spain.

The resin must be chosen of a solid consistence, almost without either taste or smell, and not at all tenacious, which distinguishes it from the false turpentine of Venice, commonly substituted for it, which has a brisker smell, a bitter taste, and sticks much to the fingers. This turpentine of Chio is indisputably the best, but its scarcity occasions it to be little in use.

The turpentine of Venice is falsely so called; for, though there was a tarpentine anciently brought from Venice, yet that now so called comes from

**Dauphine.** It is liquid, of the consistence of a thick syrup, and whitish; and flows either spontaneously or by incision, from the larix, or larch-tree, chiefly in the wood de Pilatze.

That flowing naturally, called by the peasants bijon, is a kind of balsam, not inferior in virtue to that of Peru, for which it is frequently substituted. That drawn by incision, after the tree has ceased to yield spontaneously, is of considerable use in several arts, and it is even of this that varnish is chiefly made. It must be chosen white and transparent, and care be taken that it be not counterfeited with oil of turpentine.

The turpentine of Bourdeaux is white, and as thick as honey. It does not ooze from the tree in the manner it is sent to us, but is properly a composition, wherein, among other ingredients, is a white hard sort of resin, called galipot. See the article **PITCH**.

The turpentine of Strasburg, the produce of the abies, or silver fir, is that most commonly used among us, and is preferred by our people to that of Venice, which is distinguished from it by its green hue, fragrant smell, and citron flavour.

The uses of turpentine in medicine are innumerable. It is a great vulnerary, and very detergent, and as such is prescribed in abscesses, ulcerations, &c. It promotes expectoration, and as such is prescribed in diseases of the lungs and breast; but it is most famous for clearing the urinary passages, and as such prescribed in obstructions of the reins, in gonorrhœas, &c.

**Oil of TURPENTINE.** There are two kinds of oil drawn from turpentine, by distillation; the first, white, the second red, both esteemed as balsams proper for the cure of wounds, chilblains, &c. But they are so little used among us, that it is not easy to procure either of them.

What is commonly sold under the name of oil of turpentine, or etherial oil, is only a distillation of the resinous juice of the tree, fresh as it is gathered. It is used with success in the cure of green wounds, as also by the painters, farriers, &c.

To be good, it must be clear and pellucid as water, of a strong penetrating smell, and very inflammable.

**TURPENTINE-TREE**, *Terebinthus*, in botany, a species of pistacia. See the articles **PISTACIA** and **TEREBINTHUS**.

**TURQUOISE**, or **TURCOISE**. See the article **TURCOISE**.

**TURRITIS**, tower-mustard, in botany, a genus of plants, whose flower is tetrapetalous and cruciform, the petals are ovato-oblong, obtuse, erect, and intire, with upright unguis: the stamina are awl-shaped and erect; and the fruit is a very long four-cornered pod, containing a great number of roundish emarginated seeds.

This genus grows wild on old walls, ruins, &c. in many parts of England.

**TURUNDA**, in medicine and surgery, denotes a tent, pellet, or pencil; or a piece of lint thrust into a wound, ulcer, &c. See **TENT**, &c.

**TURTLE**, in ichthyology, a name given to some species of the testudo, as the hawk's-bill turtle is the testudo with acuminated unguis, four on the hinder as well as the fore feet; the green turtle, or the testudo with two unguis on the fore feet, and one on the hinder; and the long-headed turtle, or the great oval-headed testudo.

**TURTLE-DOVE**, is a species of the columba kept tame. See **COLUMBA**.

**TUSCAN ORDER**, in architecture, the first, simplest, and most massive of the five orders.

The Tuscan is called the Rustic by Vitruvius, and M. de Cambray agrees with him, who in his parallel, says, it never ought to be used but in country houses and palace. M. Le Clerc adds, that in the manner Vitruvius, Palladio, and some others, have ordered it, it does not deserve to be used at all. But in Vignola's composition, he allows it a beauty, even in its simplicity, and such as makes it proper, not only for private houses, but even for public buildings, as in the piazzas of squares and markets, in the magazines and granaries of cities, and even in the offices and lower apartments of palaces.

The Tuscan has its character and proportions as well as the other orders; but we have no ancient monuments to give us any regular Tuscan pillar for a standard.

M. Perrault observes, that the characters of the Tuscan are nearly the same with those of the Doric, and adds, that the Tuscan in effect no more than the Doric made something stronger, by shortening the shaft of the column; and simpler, by the small number, and largeness of the mouldings.

Vitruvius makes the whole height of the order fourteen modules, in which he is followed by Vignola, M. Le Clerc, &c. Serlio makes it but twelve. Palladio gives us but one Tuscan profile, much the same as that of Vitruvius, and another too rich, on which side Scamozzi is too faulty. Hence it is, that that of Vignola, who has made the order very regular, is most followed by the modern architects.

Of all the orders, the Tuscan is the most easily executed, as having neither triglyphs nor dentils, nor modillions, to cramp its intercolumns. On this account, the columns of this order may be ranged in any of the five manners of Vitruvius, viz. the pycnostyle, systyle, eustyle, diastyle, and aræostyle.

**TUSCAN Order by Proportions of equal Parts.**

The height of the pedestal, being two diameters, is divided into four, giving one to the base, whose plinth is seven-eighths thereof, the other part is divided

vided into three, giving one to the fillet, and two to the hollow. The breadth of the die or naked, is one diameter and one-third, and the projection of the base is equal to its height; the fillet hath three-fourths thereof. The height of the cornice is half the base, being one-eighth of the whole height, and is divided into eight, giving two to the hollow, one to the fillet, and five to the band; the projection is equal to the base, and the fillet has three of these parts. Base of the column: the height is one half a diameter, and is divided into six parts, giving three to the plinth, two and a half to the torus, and half a part to the fillet; the whole projection is half of its height. The hollow, or cinctus, is one fourth of a circle, in all the orders, and belongs to the shaft of the column.

The diminishing of this column is one-fourth of the diameter, and is divided into nine, giving two and a half to the frieze of the capital, half a part to the fillet, three to the ovolo, and three to the abacus. The whole projection is one-eighth of the diameter, being perpendicular to the body of the column below, and the fillet projects equal to its height. The collarino, or necking of all the orders in general, is one of those nine parts in the capital, and the fillet half a part, the projection is one and one-fourth of these parts, and the fillet equal to its height. The height of the entablature being one diameter and three-fourths, is divided into six, giving two to the architrave, one and a half to the frieze, and two and a half to the cornice.

For the members of the architrave, divide the height into seven parts, giving two and a half to the first face, three and a half to the second, and one to the band at top. The projection is equal to the band, and the second face a third thereof. The first face of all the architraves is perpendicular to the naked of the column at the top. For the cornice, divide the height into nine, giving one and a half to the hollow, half to the fillet, one and a half to the ovolo, two to the corona, half a part to the fillet, two to the scima recta, and one the fillet. For the projections, the hollow hath two of these parts, the ovolo three and a half, the corona six, the fillet six and a half, and the whole nine being equal to the height.

**TUSCAN-EARTH**, in the materia medica, a yellowish, white, pure bole, considerably heavy, of a very smooth surface, not easily breaking between the fingers, but adhering slightly to the tongue, and melting very readily in the mouth. It is dug in many parts of Italy, particularly about Florence, where there is a stratum of it eight or ten feet thick, at the depth of five or six feet from the surface.

It is given as a sudorific, and esteemed a great medicine in fevers, attended with diarrhoeas. See **BOLES**.

**TUSSILAGO**, coltsfoot, in botany, a genus of plants, whose flower is compound and various; the corollulæ are all hermaphrodite and tubulose, and compose the disc; and in some the female corollulæ are ligulated or wanting; the filaments in the hermaphrodites are hairy, very short, and topped with cylindraceous tubulose antheræ; the female corollulæ have a short germen, with a slender style crowned with a thick bifid stigma; the cup, which is cylindric and scaly, contains the seeds, which are single, oblong, compressed, and crowned with a hairy down. If there are any seeds following the female flowers, they are like those of the hermaphrodite.

The common coltsfoot has a long, slender, whitish, tender root, with stalks that rise to the height of a foot, which are hollow within, downy, reddish, and covered with leave, without pedicles; these are long-pointed, placed alternately, and at the top of the stalks the flowers are produced, which being decayed, the other leaves appear, which are very large, a little angular, almost round, green above, and whitish and downy underneath; it grows in moist places, and on the borders of rivers, brooks, ponds, and ditches, and flowers in the spring.

Coltsfoot is an excellent medicine to abate the sharpness of the humours, to cleanse ulcers of the breast, and to facilitate expectoration. There are many that are troubled with an asthma who cut the leaves small and mix it with tobacco for smoking, and they affirm, that they find great benefit thereby; it is also thought good so used against defluxions of rheums and superfluous humidities; many account it a good cooler and healer outwardly applied.

**TUTOR**, in the civil law, is one chosen to look to the person and estate of children left by their fathers and mothers in their minority.

**TUTOR**, is also used in our universities for a member of some college or hall, who takes on him the instruction of some young students in the arts or faculties.

**TUTSAN**, *Androsæmum*, in botany, the English name for a species of hypericum. The root of this plant is thick, woody, perennial, furnished with long fibres, and has a resinous taste; the stalks are shrubby, rising to about two feet high; they are reddish, round, firm, woody, smooth, and send out some small branches toward the top; these and the stalks are furnished all the year with oval cordated leaves without pedicles, placed opposite by pairs at each joint; they are of a brownish-green at the beginning of summer, but in autumn they are of a dark-red, and seem to be perforated with a great number of holes, but, on close examination, these are found to be small bladders full of a clear, balsamic fluid: the flowers grow on the top of the branches, and are each composed of five large yellow petals, with a number of hairy stamina, like those

those of the hypericum or St. John's-wort. See **HYPERICUM**.

This plant appears like a small shrub, and grows naturally in woods in several parts of England; it flowers in June. The seeds are ripe in autumn, and the plant may at that time be propagated by parting the roots. It is called tutfan, which signifies all-heal, because it has been said to cure all sorts of disorders; notwithstanding which, it is seldom used in medicine, though it has the same virtues as St. John's-wort.

**TUTTY**, *Tutia*, a recrement of mixed metals, in which lapis-calaminaris, or zink in its metallic form, is an ingredient, collected in the furnaces where brass is made from copper and calamine, and where the mixed metals are run. In these furnaces they place, under the roof and about the upper parts of the fides, rods of iron, and sometimes rolls of dry earth, about which the tutty is afterwards found. Therefore the tutty which we use in the shops at this time, owes its origin truly and properly to zink, which sublimes with a very small fire into a kind of flowers, and when fused with any other metal, flies from it in abundance under this form, and also frequently takes some part of this metal, more or less, up with it. Hence it is evident, that the tutty or cadmia of the ancients, must have been wholly different from ours, as they used no zink nor any of its ores in the furnace where they collected it. See **ZINK** and **CADMIA**.

Our tutty then is a hard and heavy semi-metallic recrement, sometimes met with in the shops in thin flat pieces or flakes, but most abundantly in tubular cylindric pieces, resembling segments of the barks of trees pushed off from the branches without breaking; these are of different lengths and diameters. The finest tutty is that of a fine deep brown on the outside, and of a yellowish tinge within; the thickest, brightest, and most granulated; the hardest to break, and that which has least foulness among it.

Tutty is celebrated as an ophthalmic, and frequently employed as such in unguents and collyria. See **COLLYRIA**.

It is to be prepared for use by heating it several times red hot, and quenching it suddenly in rose or common water; then powdering it in a mortar, and finally levigating it with a little water upon a smooth hard marble, till there does not remain the least gritty particle among it. It is then to be dropped upon a chalk-stone, and left to dry.

**TWELFTH-DAY**, or **TWELFTH-TIDE**, the festival of the Epiphany, or the manifestation of Christ to the Gentiles; so called, as being the twelfth day, exclusive, from the nativity, or Christmas-day.

**TWELVE MEN**, otherwise called jury or inquest, is a number of twelve persons, or upwards, as far as twenty-four, by whose oath, as to matters of fact, all trials pass, both in civil and criminal

cases, through all courts of the common law in this realm.

**TWILIGHT**, *Crepusculum*, that light, whether in the morning before sun-rise, or in the evening after sun-set, supposed to begin and end when the least stars that can be seen by the naked eye cease, or begin, to appear.

**TWINS**, two young ones delivered at a birth, by an animal which ordinarily brings forth but one.

**TWINS**, in astronomy, the same with Gemini. See the article **GEMINI**.

**TWY-BLADE**, ophrys, in botany. See the article **OPHRYS**.

**TYCHONIC SYSTEM**, or **HYPOTHESIS**, an order or arrangement of the heavenly bodies, of an intermediate nature between the Copernican and Ptolemaic, or participating alike of them both. See **COPERNICAN** and **PTOLEMAIC**.

This system had its name and origin from Tycho Brahe, a nobleman of Denmark, who lived in the latter part of the last century. This philosopher, though he approved of the Copernican system, yet could not reconcile himself to the motion of the earth; and being on the other hand convinced the Ptolemaic scheme could not be true, he contrived one different from either. In this the earth has no motion allowed it, but the annual and diurnal phenomena are solved by the motion of the sun about the earth, as in the Ptolemaic scheme; and those of Mercury and Venus are solved by this contrivance, though not in the same manner, nor so simply and naturally as in the Copernican system. The Tychonic system then supposed the earth in the center of the world, that is, of the firmament of stars, and also of the orbits of the sun and moon; but at the same time it made the sun the center of the planetary motions, viz. of the orbits of Mercury, Venus, Mars, Jupiter, and Saturn. Thus the sun, with all its planets, was made to revolve about the earth once a year, to solve the phenomena arising from the annual motion, and every twenty-four hours, to account for those of the diurnal motion. But this hypothesis is so monstrously absurd, and contrary to the great simplicity of nature, and in some respects, even contradictory to appearances, that it obtained but little credit, and soon gave way to the Copernican system.

After this scheme had been proposed for some time, it received a correction, by allowing the earth a motion about its axis to account for the diurnal phenomena of the heavens; and so this came to be called the semi-Tychonic system. But this was still void of the truth, and encumbered with such hypothesis, as the true mathematician and genuine philosopher could never relish.

**TYLE**, or **TILE**, in building, a sort of thin, factitious, laminated brick, used on the roofs of houses; or, more properly, a kind of fat clayey earth

earth, kneaded and moulded, of a just thickness, dried and burnt in a kiln like a brick, and used in the covering and paving of houses. See the article **BRICK**.

Tyles are made, says Mr. Leybourn, of better earth than brick-earth, and something nearer a kin to the potter's earth.

According to 17 Edward IV. the earth for tyles should be cast up before the first of November, stirred and turned before the first of February, and not made into tyles before the first of March; and should likewise be tried and severed from stones, marle, and chalk. For the method of burning them, see the article **BRICK**.

As to the method of applying tyles, some lay them dry as they come from the kiln, without mortar or any thing else; others lay them in a kind of mortar made of loam and horse-dung. In some parts, as in Kent, they lay them in moss. See the article **MORTAR**.

**TYLE**, in assaying, a small flat piece of dried earth, used to cover the vessels in which metals are in fusion.

**TYLER**, one that covers or paves with tyles. Tylers and bricklayers were incorporated 10 Eliz. under the name of master and wardens of the society of freemen of the mystery and art of tylers and bricklayers.

**TYLWITH**, in matters of heraldry and descent, is sometimes used for a tribe or family branching out of another, which the modern heralds more usually call the second or third house.

**TYMPAN**, or **TYMPANUM**, in architecture, the area of a pediment, being that part which is in a level with the naked of the frieze. Or it is the space included between the three corniches of a triangular pediment, or the two corniches of a circular one.

Sometimes the tympan is cut out, and the part filled with an iron lattice to give light, and sometimes it is enriched with sculpture in basso relievo.

**TYMPAN**, among joiners, is also applied to the panels of the doors.

**TYMPAN** of an Arch, is a triangular space or table in the corners or sides of an arch, usually hollowed, and enriched sometimes with branches of laurel, olive-tree, or oak, or with trophies, &c. sometimes with flying figures, as fame, &c. or sitting figures, as the cardinal virtues.

**TYMPAN**, among printers, a double frame belonging to the press, covered with parchment, on which the blank sheets are laid in order to be printed off.

**TYMPANUM**, or **TYMPAN**, in mechanics, a kind of wheel placed round an axis or cylindrical beam, on the top of which are two levers or fixed staves, for the more easy turning the axis, in order to raise a weight required. The tympanum is much

the same with the peritrochium, but that the cylinder of the axis of the peritrochium is much shorter, and less than the cylinder of the tympanum.

**TYMPANUM** of a Machine, is also used for an hollow wheel, wherein one or more people, or other animals, walk to turn it; such as that of some cranes, calenders, &c.

**TYMPANUM**, in anatomy, the middle part of the ear. See **EAR**.

**TYMPANY**, *Tympanites*, in medicine, a flatulent tumour or swelling of the abdomen or belly, very hard, equable and permanent, whereby the skin is stretched so tight, that when struck it gives a sound like that of a drum. Hoffman observes, that this disease has been generally accounted, both by the ancients and moderns, a species of dropsy, but very improperly, for though it is often productive of, or complicated with an ascites, yet it is in itself a perfectly distinct disease, and accompanied with no extravasation of water in the abdomen; persons who have died of it having been found, on opening the body, with the abdomen as dry as in a state of health; but the stomach has been found, in some, greatly distended with flatulencies, and containing a viscid humour, though in no great quantity. The intestines are also usually found distended, and, as it were, pellucid, and, on being pricked, they collapse, without the appearance of any water. And, in some cases, on opening the abdomen, the whole swelling has subsided, on the exclusion of a gross flatulence which had distended it. The intestines have, in some subjects, been found distended to the bigness of a man's thigh, in some parts, and in others, lower down, so contorted and twisted together, that there could be no passage either for the wind or the excrements. It is not uncommon also, on dissection, to find great numbers of worms, of the common long kind, in the intestines. See the article **DROPSY**.

A tympany, without a dropsy, is most incident to women after labour, when the lochia have been suppressed by colds or otherwise, or discharged in too small quantities; a bad regimen during the lying-in, and the omitting to swathe the belly properly down, has also often a bad effect this way. In cases of this kind, women find soon afterwards the abdomen inflated, with a considerable uneasiness, a difficulty of breathing, costiveness, and an unaccountable anxiety. These are the breeding symptoms of the approaching tympany; and the same often happens after unskilful treatment in abortions, and after the leaving a part of the lochia behind, or the injuring the uterus in delivery.

Children are also subject to tympanies, when violently afflicted with worms, and sometimes after the measles and small-pox; and if due care is not taken of these cases, at their beginning, the superior parts soon become extenuated, and the patient dies. Ex-

trema voracity of children also, and their eating great quantities of food, at a time when the stomach is weak, sometimes brings on this disorder.

The tympany is justly accounted one of the most dangerous kinds of diseases, since the persons afflicted with it much oftener die than recover. When it is accompanied with a dropsy, it is scarce ever cured; and a simple tympany in women and children, if neglected at first, degenerates into a chronic disorder, and hardly admits of a cure. Some indeed, have gone so far as to say, they never knew a patient, afflicted with a tympany, recover; but this seems too rash a judgment. That distention of the abdomen, which is properly called a flatulent colic, is by some accounted a species of tympany: but this is not naturally dangerous, and is easily cured, except when it is attended with spasms of the viscera; in which case the medicines given to restore the due tone of the intestines, are by no means proper in regard to the spasms.

In curing flatulencies of the stomach and intestines, the physician's principal intention is to promote a discharge of the vapours by the anus, and to attenuate and gently carry off, by stool, the tough and viscid matter which contributes to the generation of the flatulencies. For this purpose, first derivative, discutient, and evacuating clysters are to be used, such as those prepared of hyssop, clary, flowers of common and Roman chamomile, tops of yarrow, juniper-berries, and the larger carminative seeds, with veal broth, adding a sufficient quantity of sal gemmæ, sal ammoniac, or Epsom salt, and the oil of chamomile. But it is to be observed, that one or two clysters are not sufficient for removing the disorder, but they are frequently to be repeated. With these are to be interposed laxatives, possessed of a carminative, and, at the same time, somewhat of an anodyne quality. Or, if the patient is strong, and the inflation a real tympanites, two parts of the extractum panchymagogum crolli, with one part of the pilulæ wildeganſi, or of the pilulæ starckii, or pilulæ de styrace, in some spirituous carminative water, is to be exhibited.

After these are to be used medicines possessed of a moderate balsamic principle, and a volatile, oleous, and aromatic salt, commonly called carminatives; but the operation of these medicines is not to be so explained, as if, by their subtle volatile salt, they attenuate the matter of the flatulencies and render it thinner; but rather, because, by invigorating the tone and systole of the intestinal coats, they hinder the stagnation of the flatulencies, move them from their seat, and render them more capable of being easily eliminated, or prevent the generation of new flatulencies; for, as the destroyed peristaltic motion of the stomach and intestines is the principal cause of flatulencies, so all medicines which have a remarkable virtue in strengthening these parts, are most proper for the removal of this disorder.

The best and most approved of this kind, are powders prepared of the roots of wake-robin, zedoary, and white burnet; the digestive salt of sylvius, or vitriolated tartar; cumin seeds, the tops of the lesser centaury, and dried orange-peel, each a dram, and six drops of the genuine oil of chamomile, or of the oil of cedar, or of the oil of orange-peel; to which, if there is a suspicion of an acid lodged in the primæ viæ, we may commodiously add crabs-eyes.

To this class of medicines may be referred the following liquid form: Take of the carminative water of Dorncrellius, of the waters of common chamomile and zedoary prepared with wine, each one ounce; of the spiritus nitri dulcis, of the pure oil of carraway, eight drops mixed with two drams of sugar.

Nor are external remedies, such as liniments, applied by way of ointment to the whole epigastric region, to be neglected. The principal ingredients of these liniments, ought to be boiled with oils of chamomile and rue, oil of nutmeg and Peruvian balsam, with which may be mixed the oils of juniper, carraway, anise, or cumins. But preferable to all others, the liquid balsam of life may be used, which when mixed with three parts of Hungary-water, and applied by way of ointment to the abdomen, or laid on with a warm linen cloth, is found of great efficacy.

TYPE, *Typus*, a copy, image, or resemblance of some model.

This word is much used, among divines, to signify a symbol, sign, or figure of something to come; in which sense it is commonly used with relation to antitype, which is the thing itself, whereof the other is a type or figure. See ANTITYPE.

TYPE of *Constans*, a formulary or model of faith, published by the emperor Constans, who being a favourer of the Monothelites, and exasperated at the little success which the ecsthesis of his uncle Heraclius had met with, published a new formulary in the manner of an edict, in 648, forbidding all persons to make use of the expressions "one" or "two wills in Jesus Christ."

Martin I. condemned the type in the Lutheran council, anno 649, and the synod made a canon expressly against this heretical model; at which the emperor was so enraged, that he forced the pope into banishment. See ECTHESIS.

TYPE, among letter-founders and printers, the same with letter. See LETTER.

TYPE, is also used to denote the order observed in the intension and remission of fevers, pulses, &c.

TYPHA, in botany, a genus producing male and female flowers on the same plant, neither having any corolla; the male flowers are collected into a cylindric amentum, each consisting of a triphillous setaceous calyx, with three capillary filaments, terminated with oblong pendulous antheræ; the female flowers are numerous and collected in an amentum,

mentum, the cup is formed of downy hairs, and the fruit, which is in a cylinder, and numerous, contains ovate seeds crowned with down.

**TYPHODES**, τυφώδες, or τυφός, in medicine, a kind of ardent or burning fever, usually attending on erysipelas of any of the viscera.

Of this disorder, according to Hippocrates, there are five species. The first is a legitimate continual fever, which impairs the strength, is accompanied with a pain of the belly, and a preternatural heat of the eyes, hinders the patient from looking steadily on any object whatsoever, and renders him unable, in consequence of the violent pain, to speak.

The second species begins with a tertian or quartan fever. The patient discharges a great quantity of saliva and worms from his mouth; his eyes are painful; his feet, and sometimes his whole body, are seized with soft swellings; his breast is now and then painful; his belly rumbles, his eyes are fierce, he spits a great deal, and his saliva sticks to his throat.

The third species is known by intense pains in the joints, and sometimes over all the body; the blood contaminated by the bile, becomes hot, and stagnates in the limbs.

The fourth species is known by a violent tension,

elevation, and heat of the abdomen, succeeded by a diarrhoea, which sometimes ends in a dropy.

The fifth species is not unlike the first. See the article **FEVER**.

**TYPHOIDEA**, in botany, the same with phleum. See the article **PHLEUM**.

**TYPHOMANIA**, τυφομανία, in medicine, a disorder of the brain, wherein the patient not being able to sleep, though greatly inclined thereto, lies with his eyes shut, talks absurdly, and flings himself this way and that.

The typhomania is a kind of combination of a frenzy with a lethargy, and is much the same with a coma vigil. See **COMA**.

**TYPOGRAPHY**, the art of printing. See the article **PRINTING**.

**TYRANT**, *Tyrannus*, among the ancients, denoted simply a king or monarch. But the ill use several persons invested with that sacred character made of it, has altered the import of the word, and tyrant now carries with it the idea of an unjust and cruel prince.

**TYROSIS**, a disorder of the stomach, proceeding from milk coagulated therein.

**TYTH**, or **TITHE**. See the article **TITHE**.

**TYTHING**. See the article **TITHING**.

## V A C

**U**, The twentieth letter, and fifth vowel, of our alphabet, is formed in the voice by a round configuration of the lips, and a greater extrusion of the under one than in forming the letter *o*, and the tongue is also more cannulated. The sound is short in *curst*, *must*, *tun*, *tub*; but is lengthened by a final *e*, as in *tune*, *tube*, &c. In some words it is rather acute than long; as in *brute*, *flute*, *lute*, &c. It is mostly long in polysyllables; as in *union*, *curious*, &c. but in some words it is obscure, as in *nature*, *venture*, &c. This letter, in the form *V*, is properly a consonant, and as such is placed before all the vowels; as in *vacant*, *venal*, *vibrate*, &c. Though the letters *v* and *u* had always two sounds, they had only the form *v* till the beginning of the fourth century, when the other form was introduced, the inconvenience of expressing two different sounds by the same letter having been observed long before.

In numerals *V* stands for five; and with a dash added at top, thus, *Ṽ*, it signifies five thousand.

In abbreviations among the Romans, *V. A.* stood for *Veterani assignati*; *V. B.* *virī bono*; *V. B. A.* *virī boni arbitrati*; *V. B. F.* *vir bonæ fidei*; *V. C.* *vir consularis*; *V. C. C. F.* *vale, conjux charissime, feliciter*; *V. D. D.* *voto dedicatur*; *V. G.* *verbi gratia*; *Vir. Ve.* *virgo vefalis*; *VL.* *videlicet*; *V. N.* *quantum nonarum*.

**VACANCY**, in philosophy. See the article **VACUUM**.

**VACANCY**, in law, a post, or benefice, wanting a regular officer or incumbent.

**VACATION**, in law, is the whole time betwixt the end of one term and the beginning of another. See **TERM**.

**VACCA MARINA**, the sea-cow, in zoology, the same with the *thrichecus*. See the article **THRICHECUS**.

## U

## V A C

**VACCINIUM**, the whortle-berry bush, in botany, a genus of plants, whose flower is monopetalous and campanulated, and the edge divided into four revolute segments; the stamina consists of eight filaments, topped with horned antheræ, with two awns on their back, which spread afunder; the fruit is an umbilicated globose berry, having four cells, which contain a few small seeds.

This genus comprehends the *vitis idæa* and *oxycoccos* of Tournefort.

**VACUUM**, or **VACUITY**, in philosophy, denotes a space, empty or devoid of all matter or body.

It has been the opinion of some philosophers, particularly the Cartesians, that nature admits not a vacuum, but that the universe is entirely full of matter: in consequence of which opinion they were obliged to assert, that if every thing contained in a vessel could be taken out, or annihilated, the sides of that vessel, however strong, would come together; but this is contrary to experience, for the greatest part of the air may be drawn out of a vessel by means of the air-pump, notwithstanding which it will remain whole, if its sides are strong enough to support the weight of the incumbent atmosphere.

Should it be objected here, that it is impossible to extract all the air out of a vessel, and that there will not be a vacuum on that account; the answer is, that since a very great part of the air that was in the vessel may be drawn out, as appears by the more quick descent of light bodies in a receiver when exhausted of its air, there must be some vacuities between the parts of the remaining air; which is sufficient to constitute a vacuum. Indeed, to this it may be objected by a Cartesian, that those vacuities are filled with *materia subtilis*, that passes freely through the sides of the vessel, and gives no resistance to the falling bodies: but, as the existence of this

this *materia subtilis* can never be proved, we are not obliged to allow the objection, especially since Sir Isaac Newton has found, that all matter affords a resistance nearly in proportion to its density. See the article *PLENUM* and *CARTESIAN*.

There are many other arguments to prove this, particularly the motions of the comets through the heavenly regions, without any sensible resistance; the different weight of bodies of the same bulk, &c.

All the parts of spaces, says Sir Isaac Newton, are not equally full: for if they were, the specific gravity of the fluid which would fill the region of the air, could not, by reason of the exceeding great density of its matter, give way to the specific gravity of quicksilver, gold, or any body, how dense soever: whence neither gold, nor any other body, could descend in the air; for no body can descend in a fluid, unless it be specifically heavier than it. But, if a quantity of matter may, by rarefaction, be diminished in a given space, why may it not diminish in infinitum? And if all the solid particles of bodies are of the same density, and cannot be rarified, without living pores, there must be a vacuum.

*VACUUM BOYLEANUM*, is sometimes, though improperly, used to express the approach to a real vacuum, by means of an air-pump.

*VADE-MECUM*, or *VENI-MECUM*, a Latin phrase, used, in English, to express a thing that is very handy and familiar, and which one usually carries about with them; chiefly applied to some favourite book.

*VADIMONIUM*, in the civil-law, a promise, or bond, given for appearance before the judge upon a day appointed.

*VAGABOND*, or *VAGRANT*, in law. See the article *VAGRANTS*.

*VAGINA*, properly signifies a sheath, or scabbard: and the term *vagina* is used, in architecture, for the part of a terminus, because resembling a sheath, out of which the statue seems to issue.

*VAGINA*, in anatomy, a large canal, formed of a robust and strong membrane, and reaching from the external orifice, or *os pudendi*, in women, to the uterus.

The vagina is usually about six or seven fingers breadth long; but is very distensible, and capable of great dilatation; its orifice is narrower than any other part, and closed by a sphincter-muscle: its substance is membranaceous, and rugose internally, and furnished with abundance of nervous papillæ; and to this is owing its quick sensation: externally it is muscular, whereby it is enabled to embrace the penis more closely in coitu. The rugæ are largest in maids, and especially in the anterior part of the vagina; in married women they are much fainter, and seem as if worn down; and in women who have born children, they are almost entirely obli-

terated. Their use is to encrease the pleasure in coitu, both to the man and to the woman; and to render the part capable of the necessary dilatation in parturition.

About the mouth of the vagina are found certain lacunæ, or small orifices, capable of admitting a bristle: they proceed from the glandulæ substraæ, and serve to secrete a liquor for lubricating the vagina, and for stimulating to venery. See the article *LACUNÆ*, &c.

The sphincter, or contracting muscle, of the vagina, is composed of a series of muscular fibres, arising from the sphincter of the anus, and surrounding the orifice of the vagina, after which it is inserted under the crura of the clitoris.

The use of the vagina is to receive the penis in coition, to emit from the womb the menstrual discharges, the foetus, the secundines, and lochia.

*VAGRANTS*, in law, are described to be persons pretending to be patent-gatherers, or collectors for prisons, and wander about for that end; among which are included all fencers, bear-wards, common players of interludes, minstrels, jugglers; all persons pretending to be gypsies, or wandering in the habits of such, or pretending skill in physiognomy, palmistry, or the like, or to tell fortunes; all such as use any subtle craft, unlawful games or plays; or, being able in body, run away, leaving their wives or children to the parish; all persons who cannot otherwise maintain themselves, that loiter about and refuse to work for the usual wages; and all other persons wandering abroad and begging, &c.

It is enacted, that where any such vagrants shall be found in a parish, the constable, or other officer, is immediately to apprehend them, and carry them before some justice of the peace, who shall examine the persons on oath, as to their condition, and places of abode; and thereupon order them to be sent by pass to the place of their last legal settlement; or if that cannot be known, to the place of their birth. The justice is to give the constable a certificate ascertaining how, and in what manner, they shall be conveyed, &c.

And justices of the peace, in their sessions, have power to appoint rates for passing of vagrants, at so much per mile. All constables are to make searches for these people before every quarter-sessions; and in case any persons permit vagrants to lodge in their houses, barns, or out-houses, and do not carry them before the next justice, or give notice to some constable, or other parish-officer, so to do, they shall forfeit a sum not above forty shillings, or under ten shillings. Also, if any charge be brought upon any place by means thereof, the same may be levied by distress and sale of the offender's goods; for want of which he shall be committed to the house of correction, and there set to hard labour for three months.

**VAGUM**, or **PAR VAGUM**, in anatomy, the eighth pair of the nerves arising from the medulla oblongata. See **NERVE**.

**VAIR**, in heraldry, a kind of fur, consisting of divers little pieces, argent and azure, resembling a Dutch U, or a bell-glass.

Vairs have their point azure opposite their point argent, and the base argent to the base azure.

**VAIRY**, **VAIRE**, **VERRY**, or **VARRY**, in heraldry, expresses a coat, or the bearings of a coat, when charged or chequered with vairs; and hence, vairy-cuppy, or vairy-tassy, is a bearing composed of pieces representing the tops of crutches.

**VALANTIA**, crosswort, in botany, a genus of plants, producing male and hermaphrodite flowers; the male flower is monopetalous, plane, and the limb divided into three or four ovate pointed segments; the corolla of the hermaphrodite flower is like the male, and contains four filaments, topped with small antheræ; the pericarpium is coriaceous, compressed, and reflexed, and contains one globose seed.

This genus is the same with the cruciata of Tournefort.

**VALENTINIANS**, in church-history, a sect of Christian heretics, who sprung up in the second century, and were so called from their leader Valentinus.

The Valentinians were only a branch of the Gnostics, who realized or personified the platonic ideas, concerning the Deity, whom they called Pleroma, or Plenitude. Their system was this: the first principle is Bythos, i. e. depth, which remained many ages unknown, having with it Ennoe, or thought, and Sige, or silence; from these sprung the Nous, or intelligence, which is the only son, equal to, and alone capable of comprehending, the Bythos; the sister of Nous they called Alatheia, or truth: and these constituted the first quaternity of æons, which were the source and original of all the rest: for Nous and Aletheia produced the World and Life; and from these two proceeded Man and the Church. But besides these eight principal æons, there were twenty-two more, the last of which, called Sophia, being desirous to arrive at the knowledge of Bythos, gave herself a great deal of uneasiness, which created in her Anger and Fear, of which was born Matter. But the Heros, or bounder, stopped her, preserved her in the Pleroma, and restored her to her perfection. Sophia then produced the Christ and the Holy Spirit, which brought the æons to their last perfection, and made every one of them contribute their utmost to form the Saviour. Her Enthymese, or thought, dwelling near the Pleroma, perfected by the Christ, produced every thing that is in the world, by its divers passions. The Christ sent into it the Saviour, accompanied by angels, who delivered it from its passions, without annihilating it: from thence was formed corporeal matter. And in

this manner did they romance, concerning God's nature, and the mysteries of the Christian religion.

**VALERIAN**, *Valeriana*, in botany, a genus of plants, whose flower consists of a single petal in form of a tube, prominent in its inferior part, and containing a honey juice; the stamina are three erect subulated filaments, topped with roundish antheræ; the fruit is a deciduous coronated capsule, containing an oblong seed. These characters are general, but there are considerable variations among the different species.

The common garden valerian has a wrinkled root, which grows near the surface of the ground, and is furnished with fibres which cross each other; the stalks rise three feet high, and are slender, round, smooth, hollow, branched, and furnished with leaves placed opposite to each other in pairs; some are smooth and entire, while others are cut deeply on each side; they are smooth, and of a pale green colour; the flowers grow in umbels on the tops of the stalks and branches, and are of a purplish white, with a sweet smell not unlike that of jasmine: it is cultivated in gardens, and propagated by parting the roots either in spring or autumn.

The wild valerian is the sort preferred for medicinal purposes; it grows on dry chalky land and shady places in divers parts of England, and flowers in May or June: the root is bitter, styptic, and has a disagreeable aromatic smell. It is recommended against the epilepsy, and is sudorific as well as hysterical; it is accounted good for the asthma, and all kinds of convulsive disorders: it may be taken in decoction, from two drams to half an ounce; and in substance, from one dram to two. The season for taking it up is in the spring, before the branches appear, and it should be dried in the shade.

Greek **VALERIAN**, *Polemonium*, in botany. See the article **POLEMONIUM**.

**VALET**, in the manege, a stick armed at one end with a blunted point of iron, to prick and aid a leaping horse.

**VALETUDINARY**, *Valetudinarius*, among medical writers, denotes a person of a weak and sickly constitution, and frequently out of order.

**VALID**, in law, an appellation given to acts, deeds, transactions, &c. which are clothed with all the formalities requisite to their being put into execution, and to their being admitted in a court of justice. See **ACT**, **DEED**, &c.

**VALLAR-CROWN**, *Vallis Coronæ*, in Roman antiquity, the same with that otherwise called castrensis. See **CROWN**.

**VALLISNERIA**, in botany, a genus producing male and female flowers on distinct plants; the male corolla is monopetalous and tripartite, and contained in a spatha, with two erect filaments topped with single antheræ: the corolla of the female flower consists of three very narrow, truncated, linear petals, with a patent pointed nectarium: the fruit is

# V A L

a long cylindric capsule, with one cell, containing a number of ovate seeds affixed to the sides of the capsule.

**VALUE, Valor**, in commerce, denotes the price or worth of any thing: hence the intrinsic value denotes the real and effective worth of a thing, and is used chiefly with regard to money, the popular value whereof may be raised and lowered at the pleasure of the prince; but its real or intrinsic value, depending wholly on its weight and fineness, is not at all affected by the stamp or impression thereon.

Value in bills of exchange, is used to signify the nature of the thing (as ready money, bills, debts, merchandizes, &c.) which is given, as it were, in exchange, for the sum specified in the bill.

From four different manners of expressing this value, some distinguish four kinds of bills of exchange. The first bears value received, simply and purely, which comprehends all kinds of value; the second, value received in money or merchandize; the third, value of myself; and, the fourth, understood. See **BILL**.

**VALVE, Valvula**, in hydraulics, pneumatics, &c. is a kind of lid, or cover, of a tube or vessel, so contrived as to open one way; but which, the more forcibly it is pressed the other way, the closer it shuts the aperture; so that it either admits the entrance of a fluid into the tube or vessel, and prevents its return; or admits its escape, and prevents its re-entrance. See **PUMP**.

Mr. Belidore has invented a new kind of valves, the description of which may not be unacceptable to the reader: see plate LXXXIX. where fig. 1. represents a round plate of brass, one half of which is chamfered upwards, and the other half downwards. The part CAD, which is greater by one twelfth than the other part B, is tapered on the under side from L to A, as is more evident in fig. 5. where the same letters are used.

The part B, is tapered on the upper side, as may also be seen in fig. 7. at BM.

On the upper side of this plate, nearer B than the center G, is screwed on an axis EHF, on which the plate turns.

Fig. 2. shews how this axis is fastened to the plate. Fig. 3. represents the box or bed of the valve, chamfered downward on all the semi-circular side L, to receive the part AL, of fig. 1. and the other part B, quite to AA, where the pivots of the axis rest, is chamfered upwards, to receive the part B, of fig. 1. coming up against it. From these chamfered edges on the inside, this bed of the valve spreads into a flat ring, to be pinched between the flanches of the pipes, which are screwed together, to make all tight.

Fig. 4. represents the section of this bed; OP being its upper part chamfered downwards, to receive GLA, the greater part of the valve of fig. 1. falling upon it; and QR chamfered upwards, re-

# V A N

ceives the smallest part B, of fig. 1. rising against it as it shuts.

The valve thus shut in its bed, is represented in fig. 5. where it may be observed, that the pivots of the axis are kept in their places by semi-circular bridles, that go over them at C and D.

The section of the same valve shut, may be seen in fig. 6. where MBHG, represents the lower and lesser part of the valve shut, and applied upwards to the under part of the bed at QR; and LAGH represents the greater part of the valve shut and applied downwards to the bed OP. K shews one of the bridles pinned, which holds down the pivots, or ends of the axis.

Fig. 7. shews the valve open, and the manner of its play; where all the passage being open between QK and BIL, and between PO and MHA, it is plain that here is the greatest water-way possible. Now, when the valve shuts, the end BM moves in the direction of the pricked curve-line MQ, and the end LA in the direction of the pricked line LO.

When the water is coming downwards, it must push hard on the part GAL, in fig. 1, 5, 6, and and 7, and thereby make the part BH to rise, by which means the valve will be close shut. But when the water comes upwards, as it presses with most force on the surface GA, the part HB will come down, and the valve will immediately open.

**VALVE**, in anatomy, a thin membrane applied on several cavities and vessels of the body, to afford a passage to certain humours going one way, and prevent their reflux towards the place from whence they came.

The veins and lymphatics are furnished with valves, which open towards the heart, but keep close towards the extremities of those vessels; that is, they let the blood and lymph pass towards the heart, but prevent their returning towards the extreme parts from whence they came.

**VANILLA**, in botany, a genus of plants, whose flower consists of five oblong patent petals, with a turbinated nectarium, tubulated at the base: the stamina are two very short filaments, sitting on the pistillum, and the antheræ are fixed to the upper lip of the nectarium: the fruit is a very long, taper, fleshy pod, including many minute seeds.

This genus is called, by Linnaeus, epidendrum. The vanilla-plant has a trailing stem, which, like ivy, fastens itself to whatever tree grows near it, by small fibres or roots produced at every joint, which fasten to the bark of the tree, and by which the plants are often nourished, when they are cut or broke off above the roots. The leaves are like those of laurel, but not quite so thick; they are produced by pairs alternately at every joint, and are of a lively green colour on the upper side, but paler underneath: the flowers are of a greenish yellow colour, mixed

mixed with white: the seeds are black and shining, and of a sub-acrid, fat, aromatic taste, with a smell like the balsam of Peru.

It is brought from Peru and Mexico, and grows in great plenty in the Bay of Campeachy: the fruit are only used in England as an ingredient in chocolate, to which it gives a pleasant flavour, to some palates; but to others it is disagreeable. The Spanish physicians in America, use it in medicine, and esteem it grateful to the stomach and brain, for expelling wind, to provoke urine, to resist poison, and cure the bite of venomous animals.

VAPOUR, *vapor*, in philosophy, the moist and most volatile particles of bodies, separated by heat, and raised into the atmosphere.

That vapours are raised from the surface of water, and moist bodies, by the action of the sun's heat, is agreed on by all: but the manner in which this is done, continues still a controverted point among philosophers. If we consult a Cartesian upon this head, he immediately tells us, that small particles of water being formed into hollow spheres by the sun's heat, filled with their *materia subtilis*, and by that means becoming lighter than air, are easily buoyed up in it: but as this *materia subtilis* is only a fiction, this solution is not to be regarded.

Dr. Nieuwentyt, and several other philosophers who maintain, that fire is a particular substance distinct from other matter, account for the formation and ascent of vapours thus: they say, that the rays of the sun, or particles of fire separated from them, adhering to particles of the water, make up little bodies, lighter than an equal bulk of air; which, therefore, by the laws of hydrostatics, will ascend in it, till they come to an height where the air is of the same specific gravity with themselves; and that rain is produced by the separation of the particles of the fire from those of the water; which last, being then left without support, can no longer be sustained by the air, but falls down in drops of rain.

This opinion is liable to the following difficulties: first, fire has never been yet proved to be a distinct element, or a particle substance; and the change of weight in bodies in chemical preparations, heretofore thought to arise from the adhesion of particles of fire, is found to proceed from the adhesion of particles of air.

Secondly, should the above-mentioned supposition be allowed, the fiery particles, which are joined to the watery ones to buoy them up, must be considerably large, or else a very great number must fix upon a single particle of water; and then a person, being on the top of a hill in the cloud, would be sensible of the heat, and find the rain, produced from that vapour, much colder than the vapour itself: whereas the contrary is evident to our senses; the tops of hills, though in the clouds, being much colder than the rain which falls below.

Besides, the manner in which the particles of water should be separated from those of the fire, so as to fall in rain, is not easily to be conceived.

The most generally received opinion is, that by the action of the sun on the surface of the water, the aqueous particles become formed into bubbles, filled with a flatus, or warm air, which renders them specifically lighter than common air, and makes them rise therein, till they meet with such as is of the same specific gravity with themselves. But Mr. Rowning asks, first, how comes the air in the bubbles to be specifically lighter than that without, since the sun's rays, which act upon the water from whence they are raised, are equally dense over all its surface?

Secondly, if it could be possible for rarer air to be separated from the denser ambient air, to form the bubbles (as bubbles of soaped water are blown up by warm air from the lungs, whilst the ambient air is colder and denser) what would hinder the external air from reducing that, which is inclosed in the bubbles immediately to the same degree of coldness and specific gravity with itself (cold being readily communicated through such thin shells of water); by which means the bubbles would become specifically heavier than the circumbient air, and would no longer be supported therein, but fall down, almost as soon as they were formed?

Thirdly, if we should grant all the rest of the supposition, yet the following difficulty will still remain. If clouds are made up of bubbles of water filled with air, why do not these bubbles always expand, when the ambient air is rarefied, and presses less upon them than it did before; and why are they not condensed, when the ambient air is condensed by the accumulation of the superior air? But if this condensation and rarefaction should happen to them, the clouds would always continue at the same height, contrary to observation; and we should never have any rain.

The two last opinions are more largely examined by Dr. Defaguliers in the Philosophical Transactions, N° 407. After which, he endeavours to establish one of his own.

He observes, with Sir Isaac Newton, that when by heat or fermentation the particles of a body are separated from the contact, their repulsive force grows stronger, and the particles exert that force at greater distances; so that the same body should be expanded into a very large space, by becoming fluid; and may sometimes take up more than a million of times the room it did in a solid and incompressible state. "Thus, says he, if the particles of water are turned into vapour, by repelling each other strongly, and repel air more than they repel each other; aggregates of each particles, made up of vapour and vacuity, may arise in air of different densities, according to their own density depending on their degree of heat." He observes farther, that heat acts more powerfully on water,

Belidor's New Valve.

Variation of the Compass.

Fig. 9. Weaving Loom &c.

water, than on common air; for that the same degree of heat, which rarefies air two-thirds, will rarefy water near fourteen thousand times, changing it into steam or vapour, as it boils it. And in winter, that small degree of heat, which, in respect of our bodies, appears cold, will raise a steam or vapour from water, at the same time that it condenses air. Lastly, he observes, that the density and rarity of this vapour depends chiefly on its degree of heat, and but little on the pressure of the circumambient air. From all which he infers, that the vapour being more rarefied near the surface of the earth, than the air is there by the same degree of heat, must necessarily be buoyed up into the atmosphere; and since it does not expand itself much, though the pressure of the incumbent air grows less, at length it finds a place where the atmosphere is of the same specific gravity with itself, and there floats, till, by some accident or other, it is converted again into drops of water, and falls down in rain.

**VAPOURS**, in medicine, a disease properly called hypo, or the hypochondriacal disease, and in men, particularly, the spleen. See **HYPOCHONDRIAC PASSION**.

**VARI**, in medicine, little hard and ruddy tumours, which frequently infect the faces of young persons of a hot temperament of body; for curing which, cathartics, and a cooling diluting diet are most proper.

**VARIABLE QUANTITIES**, in geometry and analytics, denotes such as are either continually increasing or diminishing; in opposition to those which are constant, and remaining always the same.

**VARIANCE**, in law, is an alteration of something formerly laid in a plea: but where a plea is good in substance, it is held, that a small variance shall not hurt it. Where the defendant pleads variance between a writ and declaration, he must craveoyer of the writ before he shall take any advantage thereof; and this is, because the writ and the declaration are not upon the same roll: it is likewise observed, that if in one roll a declaration is entered as in debt, and in another as in trespass, this is such a variance, that if the plaintiff has judgment it shall be reversed.

By the 16 and 17 Car. II. c. 8. all variances, &c. that are not against the right of the matter of the suit, shall be amended.

**VARIATION**, in geography and navigation, is the deviation of the magnetical needle, in the mariner's compass, from the true north point, towards either the east or west; or it is an arch of the horizon, intercepted between the meridian of the place of observation and the magnetic meridian. See the article **NEEDLE**.

The cause of this variation of the needle has remained hitherto without any demonstrative discovery; yet since its declination, and inclination (or dipping) do both of them manifestly indicate the cause

to be somewhere in the earth, it has given occasion to philosophers to frame hypotheses for a solution, which make the earth a large or general magnet or loadstone, of which all the lesser ones are but so many parts or fragments, and being possessed of the same virtue, will, when left to move freely, have the same disposition and similarity of position, and other circumstances.

The most considerable of these hypotheses is that of the late sagacious Dr. Halley, which is this: the globe of the earth is one great magnet, having four magnetical poles or points of attraction, near each pole of the equator two; and that in those parts of the world which lie near adjacent to any one of those magnetical poles, the needle is chiefly governed thereby, the nearest pole being always predominant over the more remote one. Of the north poles, that which is nearest to us, he supposes to be in the meridian of the land's-end, which governs the variations in Europe, Tartary, and the North-sea; the other he places in a meridian passing through California, about 15° from the north pole of the world, which governs the needle in North America, and the oceans on either side. In like manner he accounts for the variations in the southern hemisphere. See Phil. Trans. N° 148.

The variation of the needle from the north and south points of the horizon, not being the same, but variable in different years, and in a diverse manner in different parts of the earth, made the doctor farther conjecture, that two of the magnetic poles were fixed, and two moveable; and in order to make this out, he supposes the external part of the earth to be a shell or cortex, containing within it a magnetic moveable nucleus of a globular form, whose center of gravity is the same with that of the earth, and moveable about the same axis.

Now, if the motions of both the shell and nucleus were the same, the poles of each would always have the same position to each other; but he supposes the motion of the nucleus to be a very small matter less than that of the shell, which yet is scarce sensible in 365 revolutions; and, if so, the magnetic poles of the nucleus will by slow degrees change their distance from the magnetic poles of the shell, and thus cause a variation in that needle's variation, which is governed by the moveable pole of the nucleus, while that variation which respects the fixed poles of the magnetic shell remains more constant; as in Hudson's-bay the change is not observed to be near so fast as in these parts of Europe.

What seems a little strange is, that the doctor has no where undertook to account for the dipping of the needle by this hypothesis; though the invention of this (by Mr. Blagrave) was before that of the change of the needle's variation (by Mr. Gellibrand); nor does it appear which way this phenomenon is explicable by it. But we have not yet so many accurate observations of the needle's inclination as we

have of its variation, which is its only usual property. By several experiments Mr. Graham has very accurately made, it appears, that the quantity of the needle's inclination to the horizontal line, was an angle of about 74 or 75 degrees: that is, suppose A B (plate LXXXIX. fig. 8. N<sup>o</sup> 1.) a touched needle supported on the point C, of the pin C D, it will remain an angle A C H, or B C O, with the horizontal line H O of 74 or 75 degrees.

The variation of the needle has within a century past undergone a remarkable alteration; for at London it was observed by Mr. Burrows, in the year 1580, to be 11° 15' east; that is, if N. S. (fig. 8. N<sup>o</sup> 2.) represent the north and south points of the horizon, and E. W. the east and west points, the needle then had the situation A B, so that the arch B N = 11° 15'. After that, in the year 1622, it was observed by Mr. Gunter to be but 6° east. In the year 1634, Mr. Gellibrand observed it to be 4° 5' east. In 1657, it was observed by Mr. Bond to be nothing at all; that is, the needle placed itself in the situation S. N. and pointed directly to the north. After this, in the year 1672, Dr. Halley observed it to be 2° 30' westward; and again, in the year 1692, he found it 6° west. Since then, in the year 1722, Mr. Graham, by most accurate experiments, found it to be 14° 13'; and at present it is between 15° and 16°; and in some places it is found 18° westward.

The variation of the declination and inclination of the needle is variable, and subject to no regular computation. What the quantity of both sorts of variation is in the several parts of the world, is shewn in Dr. Halley's map of the world, improved from the observations of Mr. Pound.

If the sun's true amplitude or azimuth, found by calculation, agree with the magnetic amplitude or azimuth, found by observation, it is evident there is no variation: but if they disagree, and the true and observed amplitudes, at the rising or setting of the sun, be both of the same name; that is, either both north, or both south, their difference is the variation; whereas, if they be of different names, i. e. one north and the other south, their sum is the variation. Again, if the true and observed azimuths be both of the same name, i. e. both east or both west, their difference is the variation; but if they be of different names, their sum is the variation: and to know whether the variation be easterly or westerly, observe the following general rule; let the observer's face be turned towards the sun, then if the true amplitude or azimuth be to the right-hand, the variation is easterly; but if to the left, westerly. To illustrate this, let N E S W. (fig. 8. N<sup>o</sup> 3.) represent a compass; and suppose the sun is really E b S at the time of observation, but the observer sees him off the east point of the compass, and so the true amplitude or azimuth of the sun is to the right of the magnetic, or observed: here it is

evident, that the E b S point of the compass ought to lie where the east point is, and so the north where the N b W is; consequently the north point of the compass is too far east, i. e. the variation in this case is easterly. The same will hold when the amplitude or azimuth is taken on the west-side of the meridian.

Again, let the true amplitude or azimuth be to the left hand of the observed; thus suppose the sun is really E b N at the time of observation, but the observer sees him off the east point of the compass, and so the true amplitude or azimuth to the left of the observed: here it is evident, that the E b N point of the compass ought to stand where the east point is, and so the north where the N b E point is; consequently, the north point of the compass lies a point too far westerly, so in this case the variation is west. The same will hold when the sun is observed on the west side of the meridian.

Suppose the sun's true amplitude at rising is found to be E. 14° 20' N. but by the compass it is found to be E. 26° 12' N. Required the variation, and which way it is.

Since they are both the same way, therefore,  
from the magnetic amplitude — E. 26° 12' N.  
take the true amplitude — E. 14° 20' N.

and there remains the variation — 11 52 E. which is easterly, because in this case the true amplitude is to the right of the observed.

*VARIATION of the Moon*, in astronomy, is the third inequality observed in that planet's motion. See the article MOON.

*VARIATION of the Variation*, is the change in the declination of the needle, observed at different times in the same place.

*VARIATION of Quantities*, in algebra. See the article COMBINATION.

*VARIATION of Curvature*, in geometry, is used for that inequality or change, which happens in the curvature of all curves, except the circle; and this variation or inequality constitutes the quality of the curvature of any line.

Sir Isaac Newton makes the index of the inequality or variation of curvature to be the ratio of the fluxion of the radius of curvature to the fluxion of the curve; and Mr. Mac Laurin, to avoid the perplexity that different notions, connected with the same terms occasion to learners, has adapted the same definition; but he suggests, that this ratio gives rather the variation of the ray of curvature, and that it might have been proper to have measured the variation of curvature, rather by the ratio of the fluxion of curvature itself to the fluxion of the curve; so that the curvature being inversely as the radius of the curvature, and consequently its fluxion as the fluxion of the radius itself directly, and the square of the radius inversely, its variation would have been directly, as the measure of it, according to Sir Isaac's

definition, and inversely as the square of the radius of curvature.

**VARIATION**, in music, is understood of the different manners of playing or singing a tune or song, whether by subdividing the notes into several others of lesser value, or by adding graces, &c. in such manner, however, as that one may still discern the ground of the tune through all the enrichments; which are called embroideries.

**VARICIFORMES PARASTATÆ**, in anatomy, a name which some authors give to two vessels near the bladder, by reason of their many turnings, serving to work and prepare the seed the better. See **DEFERENTIA VASA**.

**VARIEGATION**, among botanists and florists, the streaking and diversifying the leaves of plants, and the petals of flowers, with several colours.

Those leaves whose middles are variegated with yellow or white, in spots, are called bloached; as in several varieties of holly: but when the leaves are edged with either colour, they are called striped plants.

All the different sorts of variegation in plants were at first accidental, being no more than a distemper in the plant, which, being observed, has been cherished by impoverishing the soil in which they grow, by which method their stripes are rendered more lasting and beautiful; but whatever some persons have affirmed of striping plants by art, there does not appear any foundation for such assertion, unless in woody shrubs and trees, which may be variegated by putting in a bud or graft taken from a variegated plant, where, although the buds should not grow, yet if they keep fresh but a few days, they will often communicate their miasma to the sap of the tree into which they were budded; so that, in a short time after, it has appeared very visible in the next adjoining leaves, and has afterwards spread over the greatest part of the tree; but in such plants as are herbaceous, where this operation cannot be performed, there is no way yet ascertained whereby this striping can be effected by art.

That this striping proceeds from the weakness of the plant, is evident, since it is always observed, that, whenever plants alter thus in the colour of their leaves, they do not grow so large as before, nor are they so capable of enduring cold; so that many sorts of plants, which are hardy enough to survive the cold of our climate in the open air, when in their natural verdure, require to be sheltered in the winter, after they are become variegated, and are seldom of so long continuance; which is a plain proof of its being a distemper in the plants, since, whenever they become vigorous, this striping is rendered less visible, or entirely disappears, especially if the plants are only bloached.

With some plants the venom of this morbid matter is such, that it not only tinges the leaves, but also the bark and fruit; as in the orange, pear, &c.

whose bark and fruit are striped in the same manner as their leaves.

The different colours which appear in flowers also proceed from the same cause; for the various colours which we see in the same flowers, are occasioned by the separation of the nutritive juice of plants, or from the alteration of their parts, whereby the smaller corpuscles, which are carried to the surfaces of the flower-petals, are of different forms, and thereby reflect rays of light in different proportions, whereby we have those various appearances of colour.

Of flowers which are variegated, none are more beautiful than those of the auricula, carnation, and tulip. See **AURICULA**, &c.

**VARIOLÆ**, the small-pox, in medicine. See the article **Pox**.

**VARIOLUM**, or *Gum Notis VARIOLUM*, in matters of literature, denotes an edition of a classic author, with notes of divers authors thereupon: these editions are generally most valued.

**VARIX**, in medicine, the dilatation of a vein, arising from the too great abundance or thickness of the blood; the cure of which is to be attempted by evacuations, as phlebotomy and cathartics; as also by external applications, as discutient fomentations, cataplasms, embrocations, &c. or where the case grows dangerous, by incision.

**VARNISH**, or **VERNISH**, a thick, viscid, shining liquor, used by painters, gilders, and various other artificers, to give a gloss and lustre to their works; as also to defend them from the weather, dust, &c.

There are several kinds of varnishes in use; as the siccativ or drying varnish, made of oil of aspin, turpentine, and sandarach melted together. White varnish, called also Venetian varnish, made of oil of turpentine, fine turpentine, and mastic. Spirit of wine varnish, made of sandarach, white amber, gum elemi, and varnish; serving to gild leather, picture-frames, &c. withal. Also the gilt-varnish, china varnish, common varnish, &c.

1. To make the white varnish: take gum sandarach, of the clearest and whitest sort, eight ounces; gum mastic, of the clearest sort, half an ounce; of sarcocolla, the whitest, three quarters of an ounce; Venice turpentine, an ounce and a half; benzoin, the clearest, one quarter of an ounce; white rosin, one quarter of an ounce; gum animæ, three quarters of an ounce: let all these be dissolved, and mixed in the following manner:

Put the sarcocolla and rosin into a little more spirits than will cover them to dissolve; then add the benzoin, gum animæ, and Venice turpentine, into either a glass or glazed earthen vessel, and pour on as much spirits as will cover them an inch; then put the gum mastic into a glass or glazed vessel, and pour strong spirits upon it, covering it also about an inch thick, to dissolve it rightly; then put your  
gum

gum elemi into a distinct vessel as before, and cover it with spirits to dissolve.

For this purpose, you need only break the rosin a little, and powder the gum animæ, sarcocolla, and benzoin.

Let all stand three or four days to dissolve, shaking the glasses, &c. two or three times a day, and afterwards put them all together into a glazed vessel, stirring them well, and strain the liquor and gums gently, beginning with the gums, through a linen cloth.

Then put it into a bottle, and let it stand a week before you use it, and pour off as much of the clear only, as you think sufficient for present use.

2. The white amber varnish is thus made according to Mr. Boyle: take white rosin, four drams, melt it over the fire in a clean glazed pipkin; then put into it two ounces of the whitest amber you can get, finely powdered.

This is to be put in by a little and a little, gradually, keeping it stirring all the while with a small stick, over a gentle fire, till it dissolves, pouring in now and then a little oil of turpentine, as you find it growing stiff; and continue so to do till all your amber is melted.

But great care must be taken not to set the house on fire, for the very vapours of the oil of turpentine will take fire by heat only; but if it should happen so to do, immediately put a flat board or wet blanket over the fiery pot, and by keeping the air from it, you will put it out, or suffocate it.

Therefore it will be best to melt the rosin, in a glass of a cylindric figure, in a bed of hot sand, after the glass has been well annealed, or warmed by degrees in the sand, under which you must keep a gentle fire.

When the varnish has been thus made, pour it into a coarse linen bag, and press it between two hot boards of oak or flat plates of iron; after which it may be used with any colours in painting, and also for varnishing over when painted.

But for covering gold, you must use the following varnish: mean time, it is to be observed, that when you have varnished with white varnish, you may put the things varnished into a declining oven, which will harden the varnish.

3. A hard varnish that will bear the muffle, may be thus made: take of colophony, an ounce; set it over the fire in a well-glazed earthen vessel, till it is melted; then by little and little, strew in two ounces of powder of amber, keeping it stirring all the while with a stick; and when you perceive it begin to harden or resist the stick, then put in a little turpentine oil, which will thin and soften it immediately; then put in two ounces of gum copal, finely powdered, sprinkling it in as you did the amber, now and then pouring in a little oil of turpen-

tine; and when it is done, strain it as before directed.

This is proper varnish over gold; and the things done with it must be set in a declining oven, three or four days successively, and then it will resist even the fire itself.

4. To make a varnish for brass, that will cause it to look like gold. Take two quarts of spirit of wine, and put it into a retort-glass; then add to it an ounce of gamboge, two ounces of lacca, and two ounces of mastic; let this in a sand-heat for six days, or else near a fire, or you may put the body of the bolt-head frequently into warm water, and shake it two or three times a day; then set over a pan of warm saw-dust. But before this varnish is laid over the metal, let it be well cleaned.

This is a good varnish to mix with any colours that incline to red, and the amber-varnish for mixing with those that are pale.

5. To make a varnish for gold, or metals made in imitation of gold. Take colophony, and, having melted it, put in two ounces of amber finely powdered, and some spirit of turpentine, and, as the amber thickens, keep it well stirring; then put in an ounce of gum elemi, well pulverized, and more spirit of turpentine; constantly stirring the liquor till all is well mixed and incorporated; but take care, however, to use as little turpentine as you can, because the thicker the varnish is made, the harder it will be. Let this be done over a sand heat, in an open glass; then strain it, as is directed for the preceding varnish.

This varnish is to be used alone, first warming the vessels made of paper-paste; and lay it on with a painting-brush before the fire, but not too near, lest the fire raise it into blisters. After this has been done, harden it three several times in ovens; first with a slack heat, the next with a warmer, and the third with a very hot one; and the vessels will look like polished gold.

And as for such vessels, &c. as shall be made with saw-dust and gums, the varnish may be made of the same ingredients as above mentioned, except the gum elemi; and this will dry in the sun, or in a gentle warmth.

6. To make a varnish for any thing covered with leaf silver. First paint the thing over with size, and ground chalk or whiting; let them stand till they are thoroughly dry, and then do them over with very good gold-size, of a bright colour (for there is much difference in the colour of it; some being yellow, and others almost white; the first is most proper for gold, and the last for silver.) When this size is so dry as that it will just stick a little to the touch, lay on the leaf-silver, and close it well to the size.

7. To make a varnish for silver. Melt, in a well-

well-glazed pipkin, some fine turpentine, and put in three ounces of white amber, finely powdered (more or less, according to the quantity your work will require) put it in by little and little, keeping it continually stirring, adding by degrees some spirit of turpentine, till all the amber is dissolved; and then add to it an ounce of sarcocolla well beaten, and an ounce of gum elemi well levigated, adding now and then a little spirit of turpentine, till all is dissolved: do this over a gentle fire, and keep it constantly stirring.

This varnish will be as white and strong as the former; and is to be used warm, and hardened by degrees in an oven, as varnished gold, whereby it will look like polished silver.

*Laying on of VARNISHES.* 1. If you varnish wood, let your wood be very smooth, close grained, free from grease, and rubbed with rushes.

2. Lay on your colours as smooth as possible; and, if the varnish has any blisters in it, take them off by a polish with rushes.

3. While you are varnishing, keep your work warm, but not too hot.

4. In laying on your varnish, begin in the middle, and stroke the brush to the outside; then to another extreme part, and so on till all be covered; for if you begin at the edges, the brush will leave blots there, and make the work unequal.

5. In fine works, use the finest tripoli in polishing: do not polish it at one time only, but, after the first time, let it dry for two or three days, and polish it again for the last time.

6. In the first polishing, you must use a good deal of tripoli, but in the next, a very little will serve: when you have done, wash off your your tripoli with a sponge and water; dry the varnish with a dry linen rag; and clear the work, if a white ground, with oil and whiting; or, if black, with oil and lamp-black.

VARNISH, also signifies a sort of shining coat, wherewith potter's ware, delft ware, china ware, &c. are covered, which gives them a smoothness and lustre.

Melted lead is generally used for the first, and snail for the second. See GLAZING.

VARNISH, among medallists, signifies the colours antique medals have acquired in the earth.

The beauty which nature alone is able to give to medals, and art has never yet attained to counterfeit, enhances the value of them; that is, the colour which certain soils, in which they have a long time lain, tinges the metals withal; some of which are blue, almost as beautiful as the turquoise; others with an imitable vermilion colour; others with a certain shining polished brown, vastly finer than Brasil figures.

The most usual varnish is a beautiful green, which hangs to the finest strokes without effacing them,

more accurately than the finest enamel does on metals.

No metal but brass is susceptible of this; for the green rust that gathers on silver always spoils it, and it must be got off with vinegar, or lemon-juice.

Falsifiers of medals have a false or modern varnish, which they use on their counterfeits, to give them the appearance, or air, of being antique. But this may be discovered by its softness, it being softer than the natural varnish, which is as hard as the metal itself.

Some deposite their spurious metals in the earth for a considerable time, by which means they contract a sort of varnish, which may impose upon the less knowing; others use sal armoniac, and others burnt paper.

VARRONIA, in botany, a genus of plants, whose flower is monopetalous, tubulose, cylindric, and divided at the limb into five patent segments, having five subulated filaments terminated with incumbent oblong antheræ: the fruit is an egg-shaped drupe, loosely included in the cup, containing a roundish quadrilocular nut.

VAS, a vessel, either for mechanical, chemical, culinary, or any other uses.

In anatomy, all the parts which convey a fluid are called vessels, as the veins, arteries, and lymphatics.

VASCULAR, in anatomy, something consisting of divers vessels; as arteries, veins, nerves, &c.

VASCULIFEROUS PLANTS, are such whose seeds are contained in vessels, which are sometimes divided into cells; these have always a monopetalous flower, either uniform or difform.

VASE, a term frequently used for ancient vessels dug from under ground, or otherwise found, and preserved in the cabinets of the curious.

VASE, in architecture, is also an appellation given to those ornaments placed on corniches, socles, or pedestals, representing the vessels of the ancients, particularly those used in sacrifice; as incense-pots, flower-pots, &c. They serve to crown or finish facades, or frontispieces; and hence called acroteria.

The term vase, however, is more particularly used, in architecture, to signify the body of the Corinthian and Composite capital; otherwise called the tambour or drum, and sometimes the campana or bell.

VASE, is also sometimes used, among florists, for what is more usually called the calyx, or cup. See the article CALYX.

VASSAL, in old law-books, denotes a tenant that held lands in fee of his lord, to whom he vowed fidelity and service.

VASTO, in law, a writ that lies for the heir, or him in reversion, or remainder, against the tenant for term of life or years, for making waste.

**VASTUS**, in anatomy, the name of two of the extensor muscles of the legs; the one, called vastus internus, arises from the whole internal side of the femur; and the other, called vastus externus, takes its rise from the whole external side of the femur; and both together, with the cruralis and rectus, form a very robust and strong tendon just above the knee, to which the patella adheres behind, and which is inserted below the knee at a tubercle of the tibia. See **MUSCLE**.

**VAT**, or **FAT**, a vessel for holding wine, ale, beer, cyder, &c. in the time of their preparation.

**VATERIA**, in botany, a genus of plants, whose flower consists of five ovate petals, with a great number of stamina, which are shorter than the petals; the fruit is a coriaceous, turbinate, unilocular capsule, containing one egg-shaped seed.

**VAULT**, *Fornix*, in architecture, an arched roof, so contrived that the stones which form it sustain each other. See **ARCH**.

Vaults are, on many occasions, to be preferred to soffits or flat ceilings, as they give a greater height and elevation, and are besides more firm and durable. See the article **CEILING**.

Salmasius observes, that the ancients had only three kinds of vaults. The first was the fornix, made cradle-wise; the second a testudo, i. e. tortoise-wise, which the French call cul de four, or oven-wise, and the third concha, or trumpet-wise.

But the moderns have subdivided these three sorts into many more, to which they have given different names, according to their figures and uses; some of them are circular, and others elliptical.

Again, the sweeps of some are larger, others less, portions of a sphere. All such as are above hemispheres, are called high, or surmounted, vaults; and all that are less than hemispheres, are called low, or surbated, vaults, or testudines.

In some vaults the height is greater than the diameter; in others it is less: others, again, are quite flat, and only made with haunses; others like ovens, or in the form of a cul de four, &c. and others growing wider as they lengthen, like a trumpet.

There are also gothic vaults, with ogives, &c. See **OGIVE**, &c.

Of vaults some again are single, others double, cross, diagonal, horizontal, ascending, descending, angular, oblique, pendent, &c.

*Master VAULTS* are those that cover the principal parts of buildings, in contradistinction to the upper or subordinate vaults, which only cover some little part, as a passage or gate, &c.

*Double VAULT* is one that is built over another, to make the outer decoration range with the inner; or, to make the beauty and decoration of the inside consistent with that of the outside, leaves a space between the concavity of the one and the convexity

of the other. Instances of which we have in the dome of St. Peter's at Rome, St. Paul's at London, and in that of the invalids at Paris.

*VAULTS with Compartments* are such whose sweep, or inner face, is enriched with pannels of sculpture, separated with platbands. These compartments, which are of different figures, according to the vaults, and usually gilt on a white ground, are made with stone or brick-walls, as in the church of St. Peter at Rome, or with plaster on timber-vaults.

*Theory of VAULTS*. A semi-circular arch or vault, standing on two piers, or imposts, and all the stones that compose them, being cut, and placed in such manner as that their joints or beds, being prolonged, do all meet in the center of the vault; it is evident that all the stones must be in the form of wedges; i. e. must be wider and bigger at top: by virtue of which they sustain each other, and mutually oppose the effort of their weight, which determines them to fall.

The stone in the middle of the vaults, which stands perpendicular to the horizon, and is called the key of the vault, is sustained on each side by two contiguous stones, just as by two inclined planes; and, consequently, the effort it makes to fall is not equal to its weight.

But still that effort is the greater, as the inclined planes are less inclined; so that if they were infinitely little inclined, i. e. if they were perpendicular to the horizon as well as the key, it would tend to fall with its whole weight, and would actually fall but for the mortar.

The second stone, which is on the right or left of the key-stone, is sustained by a third, which, by virtue of the figure of the vault, is necessarily more inclined to the second than the second is to the first; and consequently the second, in the effort it makes to fall, employs a less part of its weight than the first. For the same reason, the stones from the key-stone employ still a less and less part of their weight to the last, which, resting on a horizontal plane, employs no part of its weight; or, which is the same thing, makes no effort at all, as being entirely supported by the impost.

Now, in vaults, a great point to be aimed at is, that all the voussoirs, or key-stones, make an equal effort towards falling. To effect this, it is visible, that as each (reckoning from the key to the impost) employs still a less and less part of its whole weight; the first, for instance, only employing one half; the second one third; the third, one fourth, &c. There is no other way of making those different parts equal, but by a proportionable augmentation of the whole; i. e. the second stone must be heavier than the first, the third than the second, &c. to the last; which should be infinitely heavier.

M. de la Hire demonstrates what that proportion is, in which the weights of the stones of a semi-cir-

# U B I

circular arch, must be increased to be in æquilibrium, or to tend with equal forces to fall, which is the firmest disposition a vault can have.

The architects before him had no certain rule to conduct themselves by, but did all at random. Reckoning the degrees of the quadrant of a circle, from the key-stone to the impost, the extremity of each stone will take up so much the greater arch as it is farther from the key.

M. de la Hire's rule is to augment the weight of each stone above that of the key-stone, as much as the tangent of the arch of the stone exceeds the tangent of the arch of half the key. Now the tangent of the last stone of necessity becomes infinite, and of consequence its weight should be so too; but, as infinity has no place in practice, the rule amounts to this, that the last stones be loaded as much as possible, that they may the better resist the effort which the vault makes to separate them; which is called the shoot or drift of the vault.

Mr. Parent has since determined the curve, or figure, which the extrados, or outside of a vault, whose intrados, or inside, is spherical, must have, that all the stones may be in equilibrium.

*Key of a VAULT*, is a stone or brick in the middle of the vault, in form of a truncated cone, serving to bind or fasten all the rest. See the article *KEY*.

*Reins, or fillings up of a VAULT*, are the sides which sustain it.

*Pendentive of a VAULT*, is the part suspended between the arches or Ogives. See the article *PENDENTIVE*.

*Impost of a VAULT*, is the stone whereon the first vouffoir, or arch-stone of the vault, is laid. See *impost*.

**UBIQUITARIANS**, in church-history, a sect of heretics who sprung up in Germany about the year 1590, and maintained that the body of Jesus Christ is *ubique*, everywhere, or in every place, at the same time. However, they were not quite agreed among themselves; some holding, that the body of Jesus Christ, even during his mortal life, was every where; and others dating the ubiquity of his body from the time of his ascension only.

**UBIQUITY**, omnipresence; an attribute of the Deity, whereby he is always intimately present in all things; gives the esse to all things; knows, preserves, and does all in all things. See *GOD*.

For, since God cannot be said to exist in all places, as placed therein (because then he would need something to his existence, viz. place; and would have extension, parts, &c.) he must be conceived to be everywhere, or in all things, as a first, universal, efficient cause, in all his effects.

He is present therefore to all his creatures, as a pure act or an exercise of an active virtue, which knows, preserves, governs, &c. every thing. Nor

# V E G

are even finite minds present, otherwise than by operation.

**UDDER**, *Uber*, in comparative anatomy, that part in brutes wherein the milk is prepared, answering to the mammæ, or breasts, in women.

**VECTIS**, the lever, one of the mechanic powers. See the article *LEVER*.

**VECTOR**, in astronomy, a line supposed to be drawn from any planet moving round a center, or the focus of an ellipsis, to that center or focus.

This, by some writers of the new astronomy, is called vector, or radius vector, because it is that line by which the planet seems to be carried round its center, and with which it describes areas proportional to the times.

**VEDETTE**, in the military art, a sentinel on horseback detached from the main body of the army, to discover and give notice of the enemies designs.

**VEER**, a sea-term variously used. Thus veering out a rope, denotes the letting it go by hand, or letting it run out of itself. It is not used for letting out any running rope except the sheet.

**VEER** is also used in references to the wind; for, when it changes often, they say it veers about.

**VEGETABLE**, *Vegetabile*, in physiology, a term applied to all plants, considered as capable of growth, i. e. all natural bodies which have parts organically formed for generation and accretion, but not sensation.

Vegetables, according to the analyses made of them by chemistry, are distinguishable into two grand tribes, the acid and the alkaline; the first affording a volatile acid, and the second a volatile alkali, upon a dry distillation: thus guaiacum, cedar, box, cinnamon, cloves, sorrel, mint, balm, &c. afford an acid; but garlic, onions, horse-radish, scurvy-grass, mustard, &c. afford an alkali, which, rectified, is hardly distinguishable from that of animal substances, so as nearly to resemble the spirit and salt of hartshorn.

**VEGETATION**, in physiology, the act whereby plants receive their nourishment and growths; of which, three principal functions are understood, viz. nutrition, increase, and generation.

From Scripture we learn, that the earth has been endued, from the beginning, with a certain seminal virtue to produce plants; which virtue, proceeding from God, was not confined to the first production of things, but extends likewise to all future consequences of times; and this faculty which the earth has of producing plants, is from this commandment of the Almighty: "Let the earth bring forth grass, the herb yielding seed, and the fruit-tree yielding fruit after his kind, whose seed is in itself upon the earth; and it was so." Gen. i. 11.

Philosophers ask, what can be that virtue the earth is said to be endued with, if it be only an inherent quality whereby it produces, naturally, all sorts

sorts of plants, without the concurrence of seed? or if a seminal virtue (or seed) must be administered to it? Some follow the first opinion, for this reason, that earth dug up from a great depth and put into pots, after a set time or season, produces several sorts of plants of itself without seed; but though this opinion be approved of by many, it has not, however, the least appearance of probability on its side; for who (considering with attention the progress of nature, sees the marvellous mechanism of the organs of plants, the whole texture of their internal as well as external parts) could be persuaded to attribute it to a heavy and indigested mass of clay or earth: therefore, it is more rational to say, that plants have their origin from seeds, which being taken from the first plants, have propagated their species by the Creator's will, as far as our times, and will continue to do so (particularly where they are natives) to the end of the world.

The sun, rain, the exhalations of the earth, and the rest of the exterior causes, are capable to excite a certain motion or fermentation in the bosom of the earth; but unless there be a seed which contains already the conformation of the plant, whose parts are unfolded by that fermentation, never such fermentation or motion can give origin to the plant; therefore, we have great reason to think, that all plants have their origin from seeds, actually or potentially, since the first rudiments of a plant can be discovered no where else, nor by the naked eye, nor even by the help of a microscope; so that the seed contains not only the coarser matter of the plant, with its organical parts, which have the ratio of a body, but likewise a certain spirit, that is, an active and vegetative substance, which may be called the soul of the plant. Although, in some manner, it may be said to sleep in the grain or seed, yet when excited to motion by the heat of the sun, the warmth of the earth, and with rain impregnated with particles of volatile salts, it then unfolds its parts and pushes the embryo plant forward.

A sprig or cutting must contain in it this seminal property, for being set at a proper season, it produces a tree with all its generative parts; which it would not do were it not endued with some seminal virtues.

This generative or seminal faculty, is a power of the vegetative soul of a plant, by which it lives and produces its likeness for the preservation of the species: but this faculty is not discernable from the seed itself, nor from the spirit contained therein, for as the seed is said to be a part of some substance, designed for the production of another substance of the same species, it is not absolutely necessary to distinguish that prolific virtue from the seed itself, nor from the spirit contained in it; for after the seed is sown and softened by the warmth and humidity of the earth, its germ (wherein the plant is contained,

as in an epitome) is unfolded by a gentle fermentation, and arises into a plant.

That the heat of the sun and the temperate warmth and humidity of the earth, are the first principles of vegetation, appears from the sterility or fertility of the soil in those climates where these two principal agents act, or do not act, in concert; since, in the most northern countries, where the humidity of the soil is excessive, and its natural warmth is too much concentered, the fermentation of the seed being made with too much precipitation, and without that gradation necessary for the easy and most perfect expansion of the different parts of the plant, thereby they are frustrated of that strength they should have before they come out of the matrix it has been formed in to resist the injuries of the air and the inconstancies of the seasons, it perishes almost as soon as it appears on the surface of the earth; for although the earth has in some measure, though very imperfectly, acted its part (as it cannot alone, and without the assistance of the sun, carry the plant to its last perfection) that tender parent of nature, by the obliquity of its situation, being reduced to the incapacity of darting its rays as favourably and abundantly in those climates as he does in others more happily situated, cannot either help the mother earth in her pregnancy, nor rectify what she has left imperfect in her productions, which therefore die almost as soon as nature itself is apprised of their existence.

Likewise in those other climates situated quite different from these where the sun, by being too profuse of its influences, penetrates the inmost parts of the womb of the earth, and by its too violent and too often repeated acts, and exalting its salts, and evaporating its radical humidity, causes an excessive dilatation of its pores, a disunion, and but too often an intire laceration of its generative parts, so as to render them quite steril or barren, and therefore incapable to contribute to that fermentation absolutely necessary for the production of plants.

On the contrary, in those happy climates where the parts of the earth are so situated in respect to the sun as to be under his most favourable aspect, and exposed to none but his most benign influences, it almost always continues in its natural flourishing state, being seldom visited by the most powerful and penetrating beams of the sun but at those regular and periodical times appointed by nature for its pregnancy, when they are necessary to excite her fecundity, or to nourish and cherish her productions when once brought forth.

Suppose our seed to have been sown in this last soil and situation, the first things which present themselves to the imagination are the sun and earth concentering together, the one by its heat, and the other by her moisture, how to rid the embryo of that hard tough substance it is enwrapped in, and which

is the greatestt obstacle to the bursting forth of its parts; therefore the earth, which is the first agent in this case, and which is to do the office of incubation, makes use first of its natural moisture to soften the outer rind or husk, by having it percolated through the pores or pipes of the said husk, whereby they are so opened and dilated as to facilitate the introduction of the different salts appointed to operate on the whole substance of the seed, by unfolding the different parts it contains, and disposing them severally towards assuming their respective forms.

It cannot be imagined that the earth acts alone in this first operation, that it could direct itself to action without the concurrence of the sun, which on this occasion excites, by a gentle warmth, the different salts the moisture of the earth is impregnated with, that they may be capable to conquer the stubbornness of the husk, by forcing themselves into its almost imperceptible pores, conquering all the obstacles, and raising all the obstructions which the several substances may meet with; by this means a free passage being opened for such a quantity of the moisture as is necessary to make a due separation of the husk from the more essential part of the seed, the salts employed in that operation being volatilized or already fixed on that essential part, leave the husk filled with nothing else but the lymph, which groweth turgid, and being deprived of the nourishment it received when united to the substance of the seed, begins to tend towards its destruction.

The following procedure in the vegetation of plants is exemplified by Malpighi in a grain of wheat; the first day the grain is sown it grows a little turgid, and the secundine, or husk, gapes a little in several places, and the body of the plant being continued by the umbilical vessel to a conglobated leaf (which is called the pulp or flesh of the seed, and is what constitutes the flour) swells, by which means not only the gem or sprout (which is to be the future stem) opens and increases, but the roots begin to bunch out, whence the placenta, or seed-leaf, becoming loose, gapes. The second day the secundine or husk being broken through, the stem or top of the future straw appears on the outside thereof, and grows upwards by degrees; in the mean time, the seed leaf guarding the roots becomes turgid with its vesiculæ, and puts forth a white down, and the leaf being pulled away, you may see the roots of the plant bare, the future bud, leaves, and the rest of the stalk lying still hid. Between the roots and ascending stem, the trunk of the plant is knit by the navel-knot to the flower-leaf, which is very moist, though it still retains its white colour and its natural taste. The third day the pulp of the conglobated or round leaf becomes turgid with the juice it has received from the earth fermenting with its own; thus the plant increases in bigness, and in its bud or stem becomes taller, and from whitish becomes greenish,

the lateral roots also break forth greenish and pyramidal from the gaping sheaf which adheres closely to the plant, and the lower roots grow longer and hairy, with many fibres growing out of the same; indeed there are hairy fibres hanging on all the roots, except on the tops, and these fibres are seen to wind about the saline particles of the soil, little lumps of earth, &c. like ivy, whence they grow curled about the latent roots, and then break out into two other little ones. The fourth day the stem mounting upwards, makes a right angle with the seminal leaf, the last roots put forth more, and the other three growing larger are clothed with more hairs, which straitly embrace the lumps of earth, and where they meet with any vacuity, unite into a kind of net-work; the conglobate or flower-leaf is now softer, and when bruised yields a white sweetish juice, like barley cream; by stripping it off, the root and stem of the plant are plainly seen, with the intermediate navel-knot, whose outer part is solid like a bark, and in the inner more soft and medullary. The fifth day the stalk still rising puts forth a permanent or stable leaf, which is green and folded, the roots grow longer, and there appears a new tumour of a future root, the outer sheath is loosened, and the seed-leaf begins to fade. The sixth day the stable leaf being loosened, the plant mounts upwards, the sheaf still cleaving round it like a bark; the seed-leaf is now seen sinuous or wrinkled and faded, and this being freed or cut from the secundine, the flesh, or pericarpium is found of a different texture, the outer part, whereby the outside of the seed or grain is heaped up, being more solid, but the inside viscular and full of humour, especially that part next the navel-knot. All the leaves being pulled off, the roots torn, and the flower-leaf removed, the trunk appears, wherein, not far from the roots, the navel-knot bunches out, which is solid and hard to cut; above there is a mark of the sheath-leaf, which was pulled, and underneath, as in an armpit, the gem is often hid; the hind part of the plant shews the breaking forth of the roots likewise, with the faded placenta, &c. After the eleventh day, the seed-leaf as yet sticking to the plant, is crumpled and almost corrupted; within it is hollow, and about the secundine the mucus and white substance of the seed being continued to the navel-knot, forms a cavity, all the roots becoming longer, put forth new branches out of their sides, the second leaf withers, and its viscles are emptied; the internodes, or spaces between the knots, grow longer; new gems appear, and the middle root grows several inches longer. After a month, the roots and stalk being grown much longer, new buds break out at the first knot, and little tumours bunch out, which at length break out into roots.

Thus, according to Malpighi, in this short space  
4 N of

of time the plant passes through all these various changes and mutations, which, though his observations may be real as here represented, yet it does not happen with such celerity in all sorts of plants, though in some kinds all these variations may come to pass in a shorter time.

The plant carried thus far, it still wants food for the future preservation of its vegetative life, which being deprived of such nutriment, it cannot exist; of which naturalists are so sensible, that their common opinion is, that water is the great vegetable food which they endeavour to confirm by repeated experiments, especially by that made on a sprig of baum, mint, &c. which being set in a phial of pure water, without any mixture of earth, grow and put forth roots, leaves, and branches; without considering, that those sorts of plants being of a short duration, the juices which they have received from their mother earth in their first formation circulating through their vessels, being continually recruited by the salts the water they are set in is impregnated with, together with those they receive continually from the ambient atmosphere, are more than sufficient for the support of their short life in the water, which subsists no longer than that the water continues to supply them with salts, of which when once exhausted, it grows viscous, obstructs the pores of the vessels, and hinders thereby the admission of salts even from the atmosphere, imbecillitate by degrades the functions of the vegetative soul, which being forced for some time to feed on its own substance, becomes at last enervated and impotent, whereby the plant withers and dies for want of food, unless the water is changed before it comes to the last period, which appears at its growing offensive to the smell; even that precaution becomes useless, at least for the greatest part.

Those salts the water is impregnated with, being heterogeneous to those which enter into the composition of the juices, which circulate through the vessels of the plant, have soon, by disordering the whole frame of that mechanism, procured the extinction of the plant.

The great quantity of oleaginous particles those sorts of plants are composed of, which keep their pores extremely dilated for the admission of salts and other nutritive particles, contribute much towards the production of this phenomenon; but in plants of a closer texture, whose pores are so exiguous as not to be forced, but by the impetuosity of salts exalted and volatilized, best by the warmth of the earth and the heat of the sun, this experiment is of no effect; therefore, water cannot be simply considered as the great vegetable food, although it has a very considerable share in the nutriment of plants: but were it water alone, to which vegetables owe their increase, there would be no need of manures nor changing the kinds. The rain falls in all places

upon the most barren land, as well as on the most fertile; nor could there be any reason why the same field should yield a large crop of wheat one year, and not the next, since rain showers down nearly alike on the earth. See LEAF, PLANT, &c.

VEGETATIVE SOUL, among philosophers, denotes that principle in plants, by virtue of which they vegetate, or receive nourishment, and grow. See the preceding article.

VEHICLE, *Vehiculum*, in general, denotes any thing that carries or bears another along; but is more particularly used, in pharmacy, for any liquid serving to dilute some medicine, in order that it may be administered more commodiously to the patient.

VEIL, *Velum*, a piece of stuff, serving to cover or hide any thing.

A veil, or crape, is worn on the head by nuns, as a badge of their profession: the novices wear white veils; but those who have made the vows, black ones. See NUN.

VEIN, *Vena*, in anatomy, is a vessel which carries the blood from the several parts of the body to the heart.

The veins are composed principally of a membranaceous, a vasculous, and a musculous tunic: but these are vastly thinner than in the arteries. See ARTERY.

The veins are only a continuation of the extreme capillary arteries, reflected back again towards the heart, and uniting their channels as they approach it, till at last they all form three large and primary veins, viz. the cava, which brings the blood back from all parts above and below the heart; the vena portæ, which brings the blood from the liver; and the pulmonary vein. See CAVA, &c.

The best method of tracing the general course of the veins, is to begin with the main trunks, or primary veins, and end with their ramifications and capillary extremities, according to their several divisions and subdivisions.

VEIN, among miners, is that space which is bounded with woughs, and contains ore, spar, cank, clay, chirt, croil, brownhen, pitcher-chirt, cur, which the philosophers call the mother of metals, and sometimes, soil of all colours. When it bears ore, it is called a quick vein; when no ore, a dead vein. See TRACING.

VEJOURS, *Visores*, in law, are those sent by the court to take a view of any place in question, for the better decision of the right.

VELAMENTUM BOMBYCINUM, a name which some anatomists give to the velvet membrane, or inner skin of the intestines.

VELEZIA, in botany, a genus of plants, whose flower consists of five very short petals, bidentated at their margins with slender ungues the length of the cup: the stamina are six capillary filaments, topped with

with heart-shaped antheræ: the fruit is a close, cylindric, unilocular capsule, containing many seeds placed in a single series.

VELLA, Spanish-crefs, in botany, a genus of plants, whose flower is tetrapetalous and cruciform; the fruit is a globose pod, divided by an intermediate partition into two cells, containing a few roundish seeds.

VELLICATION, among physicians, the act of twitching. The word is more particularly applied to a sort of sudden convulsions that happen to the fibres of the muscles.

VELOCITY, swiftness, or that affection of motion whereby a moving body is disposed to run over a certain space in a certain time. See MOTION.

For the velocity of falling bodies, see the article ACCELERATION.

In the doctrine of fluxions it is usual to consider the velocity with which magnitudes flow, or are generated. Thus, the velocity with which a line flows, is the same as that of the point, which is supposed to describe or generate the line. The velocity with which a surface flows, is the same as the velocity of a given right-line, that, by moving parallel to itself, is supposed to generate a rectangle, always equal to the surface. The velocity with which a solid flows, may be measured by the velocity of a given plain surface that, by moving parallel to itself, is supposed to generate an erect prism, or cylinder, always equal to the solid. The velocity with which an angle flows, is measured by the velocity of a point, supposed to describe the arc of a given circle, which subtends the angle, and measures it. All these velocities are measured at any term of the time of the motion, by the spaces which would be described in a given time, by these points, lines, or surfaces, with their motions continued uniformly from that term.

The velocity with which a quantity flows, at any term of the time, while it is supposed to be generated, is called its fluxion.

VELOM, a kind of parchment, finer, evener, and whiter than the common sort. See the article PARCHMENT.

VELVET, a rich kind of stuff, all silk, covered on the outside with a close, short, fine, soft shag, the other side being a very strong close tissue.

The nap or shag, called also the velveting, of this stuff, is formed of part of the threads of the warp, which the workman puts on a long narrow-channelled ruler or needle, which he afterwards cuts, by drawing a sharp steel tool along the channel of the needle to the ends of the warp. The principal and best manufactories of velvet are in France and Italy, particularly in Venice, Milan, Florence, Genoa, and Lucca: there are others in Holland, set up by the French refugees; whereof that at Harlem is the most considerable: but they all come short of the beauty of those in France, and

accordingly, are sold for ten or fifteen *per cent.* less. There are even some brought from China, but they are the worst of all.

There are velvets of various kinds; as plain, that is, uniform and smooth, without either figures or stripes.

Figured velvet, that is, adorned and worked with divers figures, though the ground be the same with the figures; that is, the whole surface velveted.

Ramage or branched velvet, representing long stalks, branches, &c. on a fatten ground, which is sometimes of the same colour with the velvet, but more usually of a different one.

Sometimes, instead of fatten, they make the ground of gold and silver; whence the denominations of velvets with gold ground, &c.

Shorn velvet, is that wherein the threads, that make the velveting, have been ranged in the channelled ruler, but not cut there. Striped velvet, is that wherein there are stripes of divers colours running along the warp, whether these stripes be partly velvet, and partly fatten, or all velveted. Cut velvet, is that whereon the ground is a kind of taffety, or gros de tours, and the figures velvet.

Velvets are likewise distinguished, with regard to their different degrees of strength and goodness, into velvets of four threads, three threads, two threads, and a thread and a half: the first are those where there are eight threads of shag, or velveting, to each tooth of the reed; and the second have only six, and the rest four.

In general, all velvets, both worked and cut, shorn and flowered, are to have their warp and shag of organism, spun and twisted, or thrown in the mill; and their woof of silk well boiled, &c. They are all of the same breadth.

VENAL, or VENOUS, among anatomists, &c. something that bears a relation to the veins. See the article VEIN.

This word is also used for something bought with money, or procured by bribes.

VENEERING, VANEERING, or FINEERING, a kind of marquetry, or inlaying, whereby several thin slices or leaves of fine woods, of different kinds, are applied and fastened on a ground of some common wood. See MARQUETRY.

There are two kinds of inlaying; the one, which is the most common and more ordinary, goes no farther than the making of compartments of different woods; the other requires much more art, in representing flowers, birds, and the like figures.

The first kind is properly called veneering; the latter is more properly called marquetry.

The wood used in veneering is first sawed out into slices or leaves about a line in thickness; i. e. the twelfth part of an inch. In order to saw them, the blocks or planks are placed upright, in a kind of sawing press. See SAWING MILL.

These slices are afterwards cut into narrow slips, and

and fashioned divers ways, according to the design proposed; then the joints having been exactly and nicely adjusted, and the pieces brought down to their proper thickness, with several planes for the purpose, they are glued down on a ground or block, with good strong English glue.

The pieces being thus jointed and glued, the work, if small, is put in a press; if large, 'tis laid on a bench covered with a board, and pressed down with poles or pieces of wood, one end of which reaches to the ceiling of the room, and the other bears on the board.

When the glue is thoroughly dry, it is taken out of the press and finished; first with little planes, then with divers scrapers, some of which resemble rasps, which take off the dents, &c. left by the planes.

After it has been sufficiently scraped, they polish it with the skin of a sea-dog, wax and a brush, or polisher of shave grass; which is the last operation.

**VENEREAL**, something belonging to venery; as the lues venerea, french disease, or pox.

**VENERIS ŒSTRUM**, the stimulus or incentive of venery, is an appellation given by some anatomists to the clitoris.

**VENERIS ŒSTRUM** is also used by others for the transport of love, or the utmost extacy of desire, or enjoyment, in coition.

**VENERY**, is used for the act of copulation, or coition of the two sexes.

**VENERY** also denotes the act or exercise of hunting wild beasts, which are also called beasts of venery, and beasts of the forest. See the article **GAME**.

**VENESECTIION**, or **PHLEBOTOMY**, in surgery. See the article **PHLEBOTOMY**.

**VENETA BOLUS**, the Venetian bole, a fine red earth used in painting, and called in the colour-shops Venetian red. It is improperly denominated a bole, being a genuine species of red ochre. It is of a fine bright, and not very deep red, approaching, in some degree, to the colour of minium, or read-lead, and is moderately heavy, and of an even and smooth texture, yet very friable, and of a dusty surface: it adheres firmly to the tongue, is very smooth, and soft to the touch, easily crumbles to pieces between the fingers, and very much stains the skin in handling. It has a slight astringent taste, and makes no fermentation with acids. It is dug in Carinthia, and sent from Venice to all parts of the world, being an excellent colour, and very cheap; our colour-men however find many ways of adulterating it.

**VENIAL**, in the Romish theology, a term applied to slight sins, and such as easily obtain pardon. In confessing to the priests, people are not obliged to accuse themselves of all their venial sins. The thing that gives the greatest embarrass to the Roman casuists, is to distinguish between venial and mortal sins. The reformed reject this distinction of venial and mortal sins, and maintain, that all sins, how grievous soever, are venial, and all sins, how slight soever, are

mortal. And the reason they urge is, that all sins, though of their own nature mortal, yet become venial or pardonable, by virtue of our Saviour's passion, to all such as fulfil the conditions on which it is offered in the gospel.

**VENT**, **VENT-HOLE**, or **SPIRACLE**, a little aperture left in the tubes or pipes of fountains, to facilitate the air's escape; or, on occasion, to give them air, as in frosty weather, &c. for want of which they are apt to burst. See **PIPE**.

**Vent** is likewise applied to the covers of wind-furnaces, whereby the air enters, which serves them for bellows, and which are stopped with registers or sluices, according to the degree of heat required, as in the furnaces of glass-houses, assayers, &c.

**VENTER**, **BELLY**, in anatomy, a cavity in the body of an animal, containing viscera, or other organs necessary for the performance of divers functions.

**Venter** is also used in speaking of a partition of the effects of a father or mother, among children born, or accruing from different marriages.

**Venter** is also used for the children whereof a woman is delivered at one pregnancy: thus, two twins are said to be of the same venter.

**VENTER**, or **BELLY** of a muscle, is the fleshy or belly-part thereof, as contradistinguished from the two tendons, its extremes, one whereof is called the head, and the other the tail, of the muscle. See the article **MUSCLE**.

**VENTER DRACONIS**, dragon's belly, in astronomy, denotes the middle of a planet's orbit, or that part most remote from the nodes, i. e. from the dragon's head and tail; being the part which has the greatest latitude, or is at the greatest distance from the ecliptic.

**VENTIDUCTS**, in building, are spiracles or subterraneous places, where fresh cool wind being kept, they are made to communicate, by means of tubes, funnels, or vaults, with the chambers or other apartments of a house, to cool them in sultry weather.

**VENTILATOR**, a machine by which the noxious air of any close place (as an hospital, gaol, ship, chamber, &c.) may be changed for fresh air.

The noxious qualities of bad air have been long known, though not sufficiently attended to, in practice; but it is to be hoped, that the indefatigable pains taken by Dr. Hales, to set the mischiefs arising from foul air in a just light, and the remedy he has proposed by the use of his ventilators, will at length prevail over that unaccountable sloth or obstinacy, which, where particular interests are not concerned, seems to possess the generality of mankind, and which rarely allows them to give due attention to any new discovery.

The ventilators invented by that ingenious gentleman, consist of a square box, ABCD (plate XC. fig. 1.) about ten feet long, five wide, and two deep; in the middle of which is placed a broad partition,

Ventilators.

or midriff, made to move up and down, from A to C, on hinges at the end E, by means of an iron rod ZR, fixed to the midriff at Z.

Another box, of the same size with the former, having a like midriff, bar, &c. is placed near the former (fig. 2.) with its rod, RZ. Both these rods are fixed to a lever FG, moveable on the center O; so that by the alternate rising and depressing of the lever FG, the midriffs are also raised and depressed alternately, by which means these double bellows are at the same time both drawing and pouring out the air.

That the midriffs may be rendered lighter, they may be made of four bars, lengthwise, and as many placed across them, each about three inches broad, and an inch thick, the vacant spaces being filled up with thin pannels of fir board.

In order to make the midriffs move with greater ease, and without touching the sides of the boxes, there is an iron regulator NL (fig. 1.) fixed upright to the end AC of the box. As very little air will escape if the edges of the midriff be within one-twentieth part of an inch from the sides of the box, there is no necessity for leathern sides, as in common bellows. The end AC of the box must be somewhat circular, that it may be the better adapted to the rising and falling of the midriff; and at the other end of the midriff a slip of leather may be nailed over the hinges.

To the ventilators above described, eight valves are adapted for the air to pass through; these valves are placed at the hinge-end BQ, fig. 2. numbered 1, 2, 3, 4, &c. The valve 1 opens inward, to admit the air to enter, when the midriff is depressed at the other end, by means of the lever FG; and at the same time the valve 3, in the lower ventilator, is shut by the compressed air, which passes out at the valve 4: but when that midriff is raised, the valve 1 shuts, and the air passes out at the valve 2. The same is to be observed of the valves 5, 6, 7, 8, of the other box; so that when, by the motion of the lever FG, the midriffs are alternately rising and falling, then two of the ventilators are constantly drawing in the air, and two of them at the same time are blowing it out at their proper valves, the air entering at the valves 1, 3, 6, 8, and passing out at the valves 2, 4, 5, 7. To the ventilators, before the valves, is fixed a hook QQMM (fig. 3.) as a common receptacle for all the air that comes out of these valves, which air is conveyed away thro' the trunk P, passing thro' the wall of a building, &c.

From the foregoing explanation, the nature of ventilators may be easily understood, and therefore we shall be briefer in the following description of those lately erected in Newgate, for exhausting that prison of its foul air. In this prison then there are seven ventilators, each nine feet long, and four feet and a half wide; two pair of which are laid on each

other: these ventilators are worked by means of a wind-mill.

The valves of the ventilators open into a large wooden box AB (fig. 4.) which is fastened to the ventilators by the hooks AA: this box is divided into three spaces; the middle, or largest, CC, receives all the foul air discharged by the ventilators, whence it passes through a trunk DD, sixteen inches wide, through the leads into the open air.

The outer spaces BBBB, receive the foul air through the trunks FF, from the several wards, from whence it is conveyed into the ventilators, through those valves which open inward, and then discharged by the other valves of the ventilators, into the middle partition of the box, and from thence conveyed, by the pipe DD, into the open air.

These ventilators are fixed in an upper room of Newgate, in order to be near the leads, where the wind-mill, which works them, is erected; and from each of the outer nostrils FF, there are trunks, with sliding shutters, passing into the several wards; so that by opening these trunks, any of the wards may be ventilated, either singly, or several at a time.

That the midriffs may not be spoiled for want of air, when all the trunks are shut, there are two holes cut in the outer nostrils, at EE, which are covered with boxes twenty inches long, and fourteen wide. In the bottom of each of these boxes is a large moveable valve, of such a weight as not to open but when all the other passages for the air are stopped: by means of these valves, the ventilators are supplied with air, when all the trunks, going into the several wards, are closed, and the midriffs are not in danger of breaking for want of it.

The wind-mill (fig. 5.) erected for working the ventilators, is designed to move with a small degree of wind, that the ventilators may be the oftener worked.

The mill-post is fixed on four cross-trees, and supported by the braces *uwx*.

This post is hollow, that the iron rod *a*, may pass through, the lower end of it being fixed to the lever of the ventilators.

The upper end of this rod goes to the iron axle-tree, which has a crank six inches long, and therefore gives a stroke of thirteen inches; and the other end being fixed to the lever, at a proper distance from the center of its motion, raises the midriffs fifteen inches.

The iron axle-tree extends about two feet beyond the face of the sails, from the extremity of which, *p*, eight iron braces go to the vanes *m, n, o, p, q, r, s*, &c.

The frame turns on the post, on friction-wheels, so that the sails always face the wind, by means of the vane *i*; *l* is the break-pole, which, by pulling the rope *k*, stops the mill; *b, d, c, e*, are iron braces, fastened at each end with iron bolts, to keep the

frame

frame from wracking. See the article **WIND-MILL**.

Fig. 6. represents an instrument invented for going with safety into damps, and other noxious air. **XZ** represents a square piece of elder, or willow, a foot long, and two inches both in breadth and depth, with a hole, **KLQU**, five-eighths of an inch diameter, bored through it; and, at **CD**, short fosslets, with like holes bored through them; to which fosslets, hollow reed-canes are to be fixed by means of short supple leathern pipes, so as to be flexible at these joints. **N, T, S**, are square holes, two inches deep, and an inch and three quarters wide, with their leathern covers **FG, HI**, nailed over them.

**IN** is a broad leathern valve, moving on joints at **I**, so as to open, by the force of the air, which passes down the pipe **BKL**, when the breath is drawn in at the mouth at the middle fosslet, which stands five eighths of an inch above **GH**. **GS** is another like valve, which shuts the hole, at **Q**, close, while the breath drawing in, through the middle fosslet; but when, on the contrary, the person breathes out through the middle fosslet, the valve **IN** closes the hole **L**, and the other valve **GS** opens for the breath to pass freely off through the pipe **UA**; by which means the person always draws in fresh air. There are two stiff wires as **T**, fixed to prevent the valves opening too far, lest the force of the breath, which is but small, should not shut them. This instrument is to be fixed to the mouth by a tape, or cord, tied round the head; and it will be convenient to have cushions at the corners **C** and **D**, for the cheeks to bear off a part of the pressure. By the help of this instrument a person may go into a suffocating air, as in some mines, &c. his nostrils being stopped with cotton, without any danger of suffocation.

**VENTRICLE**, *ventriculus*, properly denotes any little cavity; but is more particularly used, by physicians and anatomists, for the stomach. See **STOMACH**.

For those cavities of the heart and brain, called ventricles, see **HEART** and **BRAIN**.

**VENTRILOQUOUS**, an appellation given to the *engastrimythi*.

**VENUS**, in astronomy, one of the inferior planets, revolving round the sun, in an orbit between that of mercury and the earth.

According to Mr. Cassini, the greatest distance of Venus from the earth is 38415, the mean distance 22000, and the least distance 5585, semi-diameters of the earth. Her distance from the sun is  $\frac{723}{1000}$  of the earth's distance from the sun: her excentricity  $\frac{1}{5}$ ; the inclination of her orbit  $3^{\circ} 23'$ ; and her parallax  $3'$ . See the articles **DISTANCE**, **EXCENTRICITY**, &c.

The semi-diameter of Venus is to that of the earth as 10 to 19; her periodical course round the sun is performed in 224 days, 17 hours; and her

motion round her own axis in 23 hours. See the articles, **DIAMETER** and **PERIOD**.

Venus is easily distinguished by her brightness and whiteness, which exceeds that of all the other planets, and which is so considerable, that in a dusky place she projects a sensible shadow. She constantly attends the sun, and never departs from him above  $47^{\circ}$ . When she goes before the sun, that is, rises before him, she is called Phosphorus, or Lucifer, or the morning star; and when she follows him, that is, sets after him, Hesperus, or vesper, or the evening star.

The eye in Venus will behold four planets above it, viz. our earth, Mars, Jupiter, and Saturn; and one below it, which is Mercury: and when our earth is in opposition to the sun, it will appear then (in the night) to shine with a full orb, and be very bright. The moon will appear always to accompany the earth, and never to be seen from her above half a degree. Mercury will never appear to be above  $38^{\circ}$  distant from the sun.

October 14, 1666, N. S. Cassini observed several spots in the body of this planet, by whose motion he judged (though he was not certain) that she moved either by a circulation, or a kind of libration round her axis, in about 23 hours.

A. D. 1672, and 1686, the same astronomer, with a telescope of 34 feet, believes he saw a satellite moving round this planet, and distant from it about three-fifths of Venus's diameter. It had the same phases with Venus, but was without any well defined form, and its diameter scarce one fourth of that of Venus.

Dr. Gregory thinks it more than probable, that this was a satellite; and supposes the reason why it is not usually seen, to be the unsuitness of its surface to reflect the rays of the sun's light; as is the case of the spots in the moon, of which, if the whole disc of the moon were composed, he thinks that the planet could not be seen in Venus.

Venus, when viewed through a telescope, is rarely seen to shine with a full face, but has phases just like those of the moon, being now gibbous, now horned, &c. and her illuminated part constantly turned towards the sun, i. e. looks towards the east, when Phosphorus, and towards the west when Hesperus. See **PHASES**.

M. De la Hire, in 1700, through a telescope of sixteen feet, discovered mountains in Venus, which he found to be larger than those in the moon.

Sometimes she is seen in the disc of the sun, in form of a dark round spot. See the article **TRANSIT**.

The phenomena of Venus evidently shew the falsity of the Ptolemaic system, for that system supposes that Venus's orb incloses the earth.

**VENUS**, in chemistry, the same with copper. See the article **COPPER**.

## V E R

**VENUS-LOOKING-GLASS**, in botany, the English name for a species of campanula. See **CAMPANULA**.

**VENUS-NAVELWORT**, in botany, a species of cynoglossum. See **CYNOGLOSSUM**.

**VERATRUM**, white hellebore, in botany, a genus producing hermaphrodite and male flowers on the same plant, each containing six oblong, lanceolated, persistent petals, with six subulated filaments topped with quadrangular antheræ; the male flower is barren, but the hermaphrodite is succeeded by three oblong, erect, compressed capsules, each having but one cell, containing many oblong, compressed, membranaceous seeds.

White hellebore root is oblong and tuberoso, dusky without and white within, with a great number of whitish fibres; the leaves are oblong, oval, large, rounded at their extremities, and have many longitudinal plaits; the stalks rise to about three or four feet high, branching out on every side; under each branch is placed a narrow plaited leaf; the branches and stalk are terminated with spikes of flowers, which appear in June and July. It grows naturally in several parts of Germany and Switzerland; the root is the only part used in medicine; the taste is acrid, a little bitterish, subastringent, disagreeable and nauseous; the inward use is not very safe, nor indeed the outward; for when the powder is applied to an issue, it will occasion violent purging; when taken inwardly, it is a strong emetic, and has been observed sometimes to occasion convulsions and other terrible disorders; however, in desperate cases, it may be sometimes vented upon, particularly against madness; the dose in this disease is a scruple; though even in this case it must be used with the utmost caution.

**VERB**, in grammar, a word serving to express what we affirm of any subject, or attribute to it; or, according to others, it is a word principally used to signify the affirmation, and shews that the discourse, wherein it is used, is that of a man, who not only has a conception of things, but judges or affirms something of them: though it is principally used in this sense, yet it is made use of also to signify other motions of the soul, as to desire, to pray, to command; but this it only does by changing the mood or inflexion.

The verb, in its primary signification, should have no other use, but to mark the connexion which we make in the mind, between the two terms of a proposition: but the *esse*, *to be*, is the only one that has retained this simplicity; nor, in strictness, has this retained it, but in the third person, as *est*, *is*. Men being naturally inclined to shorten their expressions, to the affirmation they have almost always added other significations, in the same word, so as that two words make a proposition; as in *Petrus vivit*, *Peter lives*; where *vivit* includes both the attribute and affirmation; it being the same

## V E R

thing to say, *Peter lives*, as that *Peter is living*; and hence the great variety of verbs in every language.

To consider simply what is essential to a verb, the only true definition is, a word signifying an affirmation; but if we should chuse to add its principal accidents, it may be defined thus; a word which signifies affirmation, with the designation of person, number, and time.

Verbs are variously divided: with respect to the subject, they are divided into active, passive, neuter, &c. with respect to their inflections, into regular, irregular, personal, impersonal, auxiliary, substantive, &c.

A verb active is a verb which expresses an action that falls on another subject or object; such as, *I love*, *I work*, &c. which signify the action of loving, working, &c. of these there are three kinds; the one called transitive, where the action passes to a subject different from the agent; reflected, where the action returns upon the agent; and reciprocal, where the action returns mutually upon the two agents that produced it.

A verb passive is that which expresses a passion, or which receives the action of some agent; and which is conjugated in the modern tongues, with the auxiliary verb *I am*, *je suis*.

A verb neuter, is that which signifies an action that has no particular object whereon to fall, but which of itself takes up the whole idea of the action, as, *I sleep*, *thou yawnest*, *he snores*, *we walk*, *you run*, *they stand*: the Latins called them neuters, because they are neither active nor passive, though they have the force and signification of both.

Of these verbs, some form their tenses by the auxiliary verb *to have*, as *I have slept*, *ye have run*; and they are called neuter actives. There are others which form their compound parts by the auxiliary *to be*, as *I am come*; these are called neuters passive.

A verb substantive is that which expresses the being or existence of a thing, as *I am*, *thou art*.

Auxiliary or helping verbs, are those which serve in conjugating active and passive verbs, such as *I am*, *I have*, &c.

Verbs in English, and most modern tongues, do not change their terminations, as in Latin, to express the several times, modes, &c. but they make use of auxiliaries, as *have*, *am*, *be*, *do*, *will*, *shall*, &c.

Regular verbs are those which are conjugated after some one manner, rule, or analogy.

Irregular or anomalous verbs, are such as have something singular in the terminations or formations of their tenses.

Verbs impersonal are those which have only the third person, as *it behooves*, &c.

**VERBAL**, something that belongs to verbs, or even to words of any kind spoken with the mouth.

Thus,

## V E R

Thus, verbal nouns, among grammarians, are those formed of verbs.

Again, a verbal contract is one made merely by word of mouth, in opposition to that made in writing.

**VERBASCUM**, mullein, in botany, a genus of plants, whose flower is monopetalous and rotated; the tube is very short and cylindric; and the limb is divided into five ovate, obtuse, patent segments: the stamina are five subulated declining filaments, topped with roundish, compressed, erect antheræ: the fruit is a roundish bilocular capsule, containing numerous angulated seeds.

There are several species of mullein; the common sort, which grows by the side of highways and banks in most parts of England, is a biennial plant, whose root is oblong, thickish, woody, with a few fibres; the lower leaves which spread on the ground, are long, broad, woolly, of a yellowish white colour, having scarce any footstalk: the stalk rises to the height of four or five feet, the lower part is furnished with leaves, and the upper terminates in a spike of yellow flowers, which appear in July, and are of an agreeable odour.

The leaves of mullein are said to soften tumours, cool inflammations, and ease pains; they are recommended in distempers of the breast, coughs, and spitting blood; the flowers are reckoned pectoral, and proper to abate the acrimony of the humours, to cure itching, and the outward and inward piles; an extract prepared from them by rectified spirit of wine, tastes extremely pleasant.

**VERBENA**, vervian, in botany, a genus of plants, whose flower is monopetalous and unequal; the tube is cylindric and incurved; and the limb is divided into five roundish segments: there is scarce any pericarpium; but the seeds, which are either two or four, are contained in the cup.

The common vervian with a blue flower, which grows near towns and villages in many parts of England, is looked upon as detergent and vulnerary; it is of a subastringent and bitterish taste, and reckoned good in all indurations and obstructions of the liver, spleen, reins, mesentery; but it is little used inwardly: externally, it is of great use in pains of the head; it was formerly accounted good against agues, but now we have better medicines, though some pretend that the bark, taken in a decoction of it, is rendered much better thereby.

**VERBERATION**, smiting, in physics, a term used to express the cause of sound, which arises from a verberation of the air, when struck in divers manners by the several parts of the sonorous body first put into a vibratory motion.

**VERBESINA**, in botany, a genus of plants, whose flower is compound and radiated, consisting of many hermaphrodite florets which form the disc, and a few ligulate female corollulæ which compose the rays; there is no pericarpium, but the cup,

## V E R

which is concave, contains the seeds, which are thick, angulated, and crowned with a three-pointed chaff.

This genus comprehends the eupatoriophalacron of Vaillant and Dillenius.

**VERDEGREASE**, or **VERDEGRIS**, a kind of rust of copper, much used by painters as a green colour.

Verdegreafe is properly no other than copper, dissolved by a mild acid into the form of an ærugo, or rust. After pressing the grapes for wine, the husks, stones, and other refuse are laid to be dried in the sun; they are then moistened with the strongest wine that can be had, and laid together in vessels till they begin to ferment; after nine or ten days the matter is pressed, and worked into balls between the hands, and laid in an orderly manner over the bottom of an earthen vessel, and as much wine is laid over them as will cover them half way up. The vessels are then covered with a loose lid, and set in a cellar where the balls are left in the wine about fifteen hours, a person turning them four or five times in that space, in order to make the wine soak perfectly through them; after this, some wooden bars are placed across the vessel, about half an inch above the surface of the wine, and the balls are laid out of the wine upon these; the vessels are then shut up, and the whole left in this state for ten days or more: at the end of this time the balls emit a very penetrating scent, and are fit for dissolving copper. They are now to be broke to pieces, and the outside mixed with the internal part, which is moister; they are then laid with thin plates of copper, *stratum super stratum*, in the same vessels upon the bars, and the whole is left for a week or a fortnight, at the end of which time the plates are found covered with verdegreafe, which is not taken off immediately: but they are wrapped up in cloths wetted with wine, and laid by a week or more, and then the ærugo or verdegreafe is taken off for use.

This rust of copper is rarely used internally, nor ought it, unless in the most desperate cases, where an instantaneous vomiting is necessary. Externally it is much used as a detergent or desiccative: it eats off fungous flesh in ulcers, and, mixed with honey, is used in aphthæ and ulcerations of the mouth. It is the basis of what is called the Egyptian ointment, and of many other compositions in the same intention. There is a preparation of this ærugo of copper, in some use at present both in medicine and in painting, which ought not to be omitted here: it is called, though very imperfectly, distilled verdegreafe; it is a crystallization of verdegreafe, prepared thus: bruise to a coarse powder some fine green verdegreafe, pour on it distilled vinegar; to the remainder continue to do this, till the liquor will no longer extract any colour from the mass. Evaporate or distil these liquors, all mixed together, till a pellicle covers the surface, then set it in a cellar, and it will shoot into

fine

fine green crystals. Evaporate the remainder of the liquor, and set it to shoot again till no more will be produced. These are the crystals of verdegrease, improperly called distilled verdegrease. They are better than the crude substance, for eating away proud flesh. A solution of them in common water is an excellent detergent for old ulcers; and they are used in common eye-waters, to clear away specks and films. These crystals, distilled in a retort, afford, after an useless phlegm is come over, a noble acid, the richest that can be procured from vinegar. It is, by the chemical writers, called acetum esuriens; it is greatly celebrated for its virtues as a menstruum, and worthy great praise, tho' not equal to all that is said of it.

**VERDERER**, or **VERDEROR**, a judicial officer of the king's forest, whose business it is to look to the vert, and see it well maintained.

**VERDICT**, is the answer of the jury given to the court, concerning the matter of fact, in any case civil or criminal, committed by the court to their trial and examination.

A verdict is either general or special. A general verdict is that which is brought into the court in like general terms as the general issue, as, in an action of disseisin, the defendant pleads no wrong, no disseisin. Then the issue is general, whether the fact be wrong or not, which being committed to the jury, they, upon consideration of the evidence, come in and say, either for the plaintiff, that it is a wrong disseisin; or for the defendant, that it is no wrong disseisin.

A special verdict, is, when they say at large, that such and such a thing they found to be done by the defendant or tenant; declaring the course of the fact, as in their opinion it is proved; and praying the judgment of the court, as to what is law in that case.

It is said, that a jury may give a general or special verdict, in all actions, and cases; and that the court is obliged to receive it, provided it be pertinent to the point in issue: also if the jury will take upon them to bring in any thing that is matter of law, their verdict shall be received.

Verdicts are also public and private; public, when the same are given in open court; and private, when given out of court, before any of the judges: but a private verdict, in strictness, is looked upon to be no verdict.

**VERDITER**, or **VERDETER**, a kind of mineral substance, sometimes used by the painters, &c. for a blue; but more usually mixed with a yellow for a green colour.

Verditer, according to Savary, ought to be made of the lapis armenus; or at least of an earthy substance much like it, brought from the mountains of Hungary, &c. only prepared by powdering it, and cleansing it by lotion.

But this stone being very rare, the verditer commonly used is not a native, but a factitious substance; which some say is prepared by casting wine or water upon new copper, as it comes red hot out of the furnace, and catching the steams that rise from it upon copper-plates; others again say, it is prepared by dissolving copper-plates in wine, much after the manner of verdegrease.

But the method of making it in England is as follows:

The refiners pour their copper-water into an hundred pound weight of whiting, stirring them well together every day for some hours, till the water grows pale; then they pour that off, and set it by for further use, and pour on more of the green water, repeating this till the verditer is made; which they then take out, and lay on large pieces of chalk in the sun to dry.

The water which is poured off from the verditer, (which remains at the bottom of the tub) is put into a copper, and boiled till it comes to the consistence of water-gruel; now, consisting principally of salt-petre reduced, most of the spirit of vitriol being gone with the copper into the verditer; and a dish full of this being put into the other materials for aqua-fortis, is redistilled, and makes what they call a double water, which is near twice as good as that made without it.

**VERDOY**, in heraldry, denotes a bordure of a coat of arms, charged with any kinds or parts of flowers, fruits, seeds, plants, &c.

**VERGE**, signifies the compass of the king's court which bounds the jurisdiction of the lord steward of the household; and which is thought to have been twelve miles round.

The term verge is also used for a stick or rod, whereby one is admitted tenant to a copyhold estate, by holding it in his hand, and swearing fealty to the lord of the manor.

**VERGERS**, certain officers of the courts of king's bench and common pleas, whose business it is to carry white wands before the judges.

There are also vergers of cathedrals and collegiate churches, who carry a rod tipped with silver before the bishop, dean, &c.

**VERGETTE**, in heraldry, denotes a pallet, or small pale; and hence, a shield divided by such pallets, is termed vergette.

**VERGILÆ**, in astronomy, a constellation, the appearance of which denotes the approach of spring: it is the same with pleiades. See **PLEIADES**.

**VERIFICATION**, in general, is the act of proving a thing; but among the French, it only signifies the recording of the king's edicts by the parliament.

**VERJUICE**, a liquor obtained from grapes or apples, unfit for wine or cyder; or from sweet ones, whilst yet acid and unripe. Its chief use is in sauces, ragouts,

ragouts, &c. though it is also an ingredient in some medicinal compositions, and is used by the wax-chandlers to purify their wax.

**VERMICELLI**, or **VERMICHELLY**, a composition of flour, cheese, yolks of eggs, sugar, and saffron, reduced to a paste, and formed into long slender pieces like worms, by forcing it with a piston through a number of little holes.

It was first brought from Italy, where it is in great vogue: it is chiefly used in soups and pottages, to provoke venery, &c.

**VERMICULAR**, an epithet given to any thing that bears a relation or resemblance to worms, *vermiculi*. See **WORM**.

Anatomists particularly apply it to the motion of the intestines and certain muscles of the body.

The vermicular or peristaltic motion of the intestines is performed by the contraction of the fibres thereof, from above downwards; as the antiperistaltic motion is by their contraction from below upwards.

**VERMIFORMIS**, in anatomy, a term applied to various parts in the human body, bearing some resemblance to worms. As some muscles, processes, &c.

*Processus*, or *apophyses* **VERMIFORMES**, two extremities of the cerebellum, situate near the fourth ventricle of the brain.

**VERMIFORMES musculi**, are the four muscles in each hand and foot, which bring the fingers and toes towards the thumbs and great toes, called also *lumbricales*.

**VERMILION**, a very bright and beautiful red colour, in great esteem among the ancients, under the name of minium. There are two kinds of it, the one natural, and the other factitious. The natural is found in some silver mines, in the form of a ruddy sand, which is afterwards prepared and purified by several lotions and coctions. The artificial is made of mineral cinnabar, ground up with aquavita and urine, and afterwards dried.

It is also made of lead burnt and washed, or of cerus prepared by fire: but this is not properly called vermilion, but minium, or red-lead. See **MINIUM**.

Yet this last, however, seems to be the real vermilion of the ancients; and both apothecaries and painters still give it the name, to enhance the price.

We have two kinds of vermilion from Holland, the one of a deep red, the other pale; but it is the same thing at the bottom: the only difference of colour proceeding from the cinnabar's being more or less ground: when the cinnabar is finely ground, the vermilion is pale: and this is preferred before that which is coarser and redder.

It is of very great use with painters in oil and miniature; and among the ladies for a fucus, or paint, to heighten the complexion of such as are too pale.

Some disapprove of vermilion to be used in painting prints, unless it be prepared by washing, as is

directed for minium; and then chiefly for dry painting, except it be by those persons who can use it moderately, and with judgment; for all heavy colours will drown the shades or strokes of the engraver.

**VERMIN**, *vermina*, a collective name including all kinds of little animals, or insects, which are hurtful or troublesome to men, beasts, fruits, &c. as worms, lice, fleas, caterpillars, ants, flies, &c.

**VERMINATION**, *verminatio*, the act of breeding worms, and other vermin; particularly bots, in cattle, &c.

**VERMINATION**, is sometimes also used, among physicians, for a sort of tormina, ventris, or wringing of the guts, wherein the patient is affected, as if worms were gnawing his intestines.

**VERMIVOROUS ANIMALS**, are such as feed upon worms.

**VERNACULAR**, is applied to any thing that is peculiar to some one country.

**VERNAL**, something belonging to the spring season.

Hence vernal leaves, are those leaves of plants which come up in the spring. Vernal signs, are those which the sun is in during the spring season, viz. Aries, Taurus, and Gemini. Vernal equinox, is that which happens when the sun is ascending from the equator towards the north pole.

**VERNIER**, or **NONIUS**, among the mathematicians, a scale of divisions, serving to cut the divisions of an arch into single minutes.

**VERONICA**, speedwell, in botany, a genus of plants, whose flower is monopetalous and rotated, with the limb divided into four ovate plane segments; the stamina are two rising filaments, topped with oblong antheræ; the fruit is a heart shaped capsule, with the top compressed, having two cells which contain many roundish seeds.

The common male speedwell, or fluellin, has a slender, fibrous, spreading root, which sends forth several slender, long, round, knotted, hairy stalks, generally lying on the surface of the ground; the leaves grow by pairs opposite to each other, and are oval, downy, and dentated on the edges, and have a bitter acrid taste; the flowers are disposed in spikes arising from the wings of the stalks, they are small and bluish, sometimes white, and appear in June: it grows wild in the woods and other shady places in divers parts of England. There are several other species belonging to this genus which are noted in medicine, but the above-mentioned is held most in esteem; it is accounted a good deterging vulnerary, and given in erosions and obstructions of the lungs; both to expectorate and heal, there are also alexipharmic qualities ascribed to it, which give it a place in some compositions against malignities and epidemical infections; it is also prescribed in some antiscorbutic decoctions, and reckoned good to cleanse the blood, and wear away blotches and cutaneous eruptions.

eruptions; it is also said to be excellent in the gravel, and is best used in the manner of tea; and is very good in sleepy disorders.

VERSE, *versus*, in poetry, a line or part of a discourse, consisting of a number of long and short syllables, which run with an agreeable cadence, the like being also reiterated in the course of the piece.

This repetition, according to F. Bossu, is necessary to distinguish the notion of verse from that of prose; for in prose, as well as verse, each period and member are parts of discourse, consisting of a certain number of long and short syllables; only prose is continually diversifying its measures and cadences, and verse regularly repeating them. This repetition of the poets appears even in the manner of writing; for one verse being finished, they return to the beginning of another line, to write the verse following, and it is to this return, that verse owes its name.

To make verse, it is not enough that the measures and quantities of syllables be observed, and six just feet put one after another in the same line. There are further required, certain agreeable cadences, particular tenues, moods, regimens, and even sometimes words unknown in prose. But what is chiefly required, is an elevated, bold, figurative manner of diction; this manner is a thing so peculiar to this kind of writing, that without it, the most exact arrangements of longs and shorts does not constitute verse so much as a sort of measured prose. The Greek and Latin verses consist of a certain number of feet, disposed in a certain order; and some have attempted to make French and English verses on the same foundation, but without success. Vossius is very severe on the modern verse, and makes it altogether unfit for music. Our verses, says he, run all as it were upon one foot, without distinction of members or parts, and without regard to the natural quantities of syllables. We have no rhythmus at all, and we mind nothing but to have a certain number of syllables in a verse of whatever nature, and in whatever order. Mr. Malcolm vindicates our verse from this imputation. It is true, says he, we do not follow the metrical composition of the ancients, yet we have such a mixture of strong and soft, long and short, syllables, as make our verses flow smooth or rumbling, flow or rapid, agreeable to the subject. Instances of all which we have in the following lines of Pope.

These equal syllables alone require,  
Tho' oft' the ear the open vowels tire,  
While expletives their feeble aid do join,  
And ten low words oft' creep in one dull line.  
Soft is the strain when Zephyr gently blows;  
And the smooth stream in smoother numbers flows;  
But when loud billows lash the sounding shore,  
The hoarse rough verse should like the torrent roar;

When Ajax strives some rock's vast weight to throw,  
The line too labours, and the words move flow.  
Not so when swift Camilla scours the plain,  
Flies o'er th' unbending corn, and skims along the main.

By making a small change or transposition of a word in any of these verses, any body who has an ear will find, that we make a great matter of the nature and order of the syllables. See NUMBERS.

Vossius adds, that the ancient odes were sung as to the rhythmus, in the same manner as we scan them, every pes being a distinct bar, or measure separated by a distinct pause, though in reading, that distinction was not accurately observed. Lastly, he observes, that their odes had a regular return of the same kind of verse, and the same quantity of syllables, in the same place of every verse; whereas, in the modern odes, to follow the natural quantity of our syllables, every stanza would be a distinct song.

Verses are of various kinds, some denominated from the number of feet, whereof they are composed, as the monometer, dimeter, trimeter, tetrameter, pentameter, hexameter, &c.

Some also, from the kinds of feet used in them, as the pyrrhichion, proceleusmatic, iambic, trochaic, &c.

Sometimes verses are denominated from the names of the inventors, or the authors who have used them with most success, as the anacreontic, archilochian, asclepiæ, alcaic, sapphic, &c.

The moderns have invented heroic or alexandrine verses; the ancients likewise invented various kinds of poetical devices in verse, as centos, echos, &c.

VERSE is also used for a part of a chapter, section, or paragraph, subdivided into several little articles. The whole Bible is divided into chapters, and the chapters are subdivided into verses. The division of verses in the New Testament was first made by one Robert Stephens, with which division many learned men find great fault, and yet it is every where followed.

VERSED *sine of an arch*, a segment of the diameter of a circle, lying between the foot of a right sine, and the lower extremity of the arch. See SINE.

VERSIFICATION, the art or manner of making verse; also the tone and cadence of verse.

Verfication is properly applied to what the poet does more by labour, art, and rule, than by invention, and the genius or furor poeticus. See POETRY, &c.

VERSION, a translation of some book or writing, out of one language into another.

VERT, in heraldry, the term for a green colour. It is called vert in the blazon of the coats of all under the degree of nobles; but in coats of nobility, it is called emerald; and in those of kings, venus. In engraving, it is expressed by diagonals,

or

or lines drawn athwart from right to left, from the dexter chief corner to the sinister base.

VERT, or GREEN HUE, in forest law, any thing that grows and bears a green leaf within the forest, that may cover a deer. This is divided into over-vert and nether-vert; over-vert is the great woods which in law-books are usually called hault-bois; nether-vert is the under woods, otherwise called sub-bois. We sometimes also meet with special vert, which denotes all trees growing in the king's woods within the forest; and those which grow in other men's woods, if they be such trees as bear fruit to feed the deer.

VERTEBRÆ, in anatomy, the twenty-four bones of which the spine consists, and on which the several motions of the trunk of our bodies are performed.

Each of these vertebræ is composed of its body and processes. The body is the thick, spongy, anterior part, which is convex before, concave backwards, horizontal and plain in most of them above and below; their anterior and posterior surfaces having several holes made in their thin external plate, both for the firmer connexion of the ligaments, and for the passages of vessels into their cellular substance. Between these bodies of each two adjoining vertebræ, a substance between the nature of ligament and cartilage is interposed; which is composed of concentric curve fibres, the exterior of which are the most solid and hard, while those in the centre are very soft and full of a glairy liquor; and therefore this substance was called by the ancients ligamentum mucosum. This is firmly fixed to the horizontal surfaces of the bodies of the vertebræ, and therefore not only allows these bones to recede from each other, and to be prest closer together without breaking, but serves to connect them, in which it is assisted by a strong membranous ligament, which lines all their concave surface, and by still a stronger ligament that covers all their anterior convex surface. It may be observed, as a general rule, notwithstanding some exceptions, that the bodies of the vertebræ are smaller and more solid above, but as we reckon downwards, appear larger and more spongy, and that the cartilages between them are thick, and the surrounding ligaments strong in proportion to the largeness of the vertebræ, and the quantity of motion they are to perform: by which disposition the greater weight is supported on the broadest best secured base, and the middle of our body is allowed a large and secure motion, which is of considerable benefit. From each side of the body of each vertebra, a bony bridge is produced backwards and to a side; from the posterior extremity of which, one slanting process rises, and another descends; the smooth, and what is generally the flattest side of each of these four processes, which are called the oblique, is covered with a smooth cartilage, and the two inferior oblique processes of each vertebra are fitted to, and articulated

with, the two superior or ascending oblique processes of the vertebra below.

From between the superior and inferior oblique process of each side, the vertebra is stretched out laterally in form of a process, that is universally named transverse. From the posterior roots of the two oblique, and of the transverse process of each side, a broad oblique bony plate is extended backwards; where these meet, the seventh and last process of the vertebræ takes its rise and stands out backwards; this being generally sharp-pointed, and narrow-edged, has therefore been called spinal process, from which this whole chain of bones has got the name spina. Besides the common ligament which lines all the interior surface of these processes as well as of the bodies, there are particular ligaments that connect the processes of each two contiguous vertebræ. The substance of the processes is considerably stronger and firmer than that of the bodies of the vertebræ, having a thicker external plate, and without so many large holes in it. The seven processes considered conjunctly, as forming the posterior shares of the vertebræ, are hollow at their anterior middle part; which concavity, joined with that at the posterior part of the bodies, makes one great foramen, which answers to such another in the vertebræ above and below; therefore the foramina of all the vertebræ taken together, form a long great conduit, which is widened or straitened in proportion to the size of the medulla spinalis, which it contains.

In the lateral bridges, which join the bodies to the processes of each vertebra, a semicircular notch is observable both above and below; which, exactly corresponding with others in the contiguous bones, when the vertebræ are joined, form a round hole in each side, between each two vertebræ, through which the nerves that proceed from the medulla spinalis and the blood vessels pass. The articulations then of these true vertebræ are plainly double; for their bodies are joined by synchondrosis, and their oblique processes are articulated by the third sort of ginglymus. Hence it is evident, that their centre of motion is altered in different positions of the trunk. For when we bow forwards the superior moved part bears entirely on the bodies of the vertebræ; if we bend back, the oblique processes support the weight; if we recline to one side, we rest upon the oblique processes of that side and part of the bodies; if we stand erect, all the bodies and oblique processes have their share in our support.

There are in all twenty-four vertebræ: the neck consists of seven; and in these, as in the others, we are to observe some things in general; and afterwards, other things in particular.

The vertebræ of the neck are smaller than those of the back; but they are of a firmer consistence, and harder: their body is more compressed than in the others, and is situated on the other part, and convex below.

# V E R

Most of these vertebræ have nine apophyses; the transverse and posterior ones, called the spinose apophyses, are usually bifurcated: the transverse ones are perforated also, for the passage of the vertebral vessels to the head.

In the consideration of the vertebræ of the neck singly, we are to observe, that the upper one has a peculiar name; it is called atlas. This wants the body and the spinose apophyses, and approaches to the figure of a ring: its substance is more solid than that of any other, and it receives both above and below; but it is not received itself.

The head is articulated at its interior part, and it is by means of this articulation that the head is bent, and extended.

The proper foramen is greater in this than in any other vertebra, which arises from its wanting the body: the transverse processes are also longer than in the others. It has also a peculiar semi-circular ligament, by which it embraces the dentiform process of the succeeding vertebra.

The second vertebra is called epistrophæus, and axis; in which we are to observe the dentiform or odontoid process, just mentioned; whereby it articulates in the manner of a hinge, with the first vertebra, and the rotatory motion of the head is performed by means of it.

The third vertebra is also called axis by some, though it has nothing to warrant such a name; for there is nothing particular to be observed in this, or any of the succeeding vertebræ of the neck, more than has already been taken notice of them in general.

The dorsum, or back, has twelve vertebræ, of which we may remark, in general, that they are of a middle size between those of the neck, and those of the loins: their spinose apophyses are also very long, and, except in the two last, very much inclined: the cartilages between the bodies of these, are smaller than those of the neck: the two transverse apophyses are thick, and have a depression in them for the articulation with the ribs. The first vertebra of the back is called the axillary, or eminent vertebra; and to it is joined the upper rib. See the article RIBS.

The vertebræ of the loins are five, of which we may observe, in general, that their bodies, and also the intervening cartilages, are very thick: the transverse apophyses very long, but smaller than those of the back: the spinose apophyses are thick, stout, and set farther asunder than in the others, to give way to a laxer motion in this part.

Some have given particular names to the vertebræ of the back and loins; but this is not necessary, as they are sufficiently distinguished by numbering them. For the luxations, fractures, and other injuries of the vertebræ, see the articles LUXATION, &c.

# V E R

VERTEX, in anatomy, denotes the crown of the head, or the uppermost part situated between the sinciput and the occiput.

Hence vertex is also used, figuratively, for the top of other things: thus the vertex of a cone, pyramid, &c. is the top of any one of these figures. See CONE, &c.

VERTEX of a Glass, in optics, the same with the pole thereof.

VERTEX, in astronomy, is also used for the point of heaven perpendicularly over our heads, properly called the zenith. See ZENITH.

Path of the VERTEX, the circle described by the vertical point during one revolution of the earth about its axis.

VERTICAL CIRCLE, in astronomy, a great circle of the sphere, passing through the zenith and nadir, and cutting the horizon at right-angles: it is otherwise called azimuth. See AZIMUTH.

Prime VERTICAL, is that vertical circle or azimuth which passes through the poles of the meridian; or which is perpendicular to the meridian, and passes through the equinoctial points.

VERTICAL of the Sun, is the vertical which passes through the center of the sun at any moment of time.

VERTICAL PLANE, in perspective, is a plane perpendicular to the geometrical plane, passing through the eye, and cutting the perspective plane at right-angles.

VERTICAL PLANE, in conics, is a plane passing through the vertex of the cone, and parallel to any conic section. See the article PLANE.

VERTICAL LINE, in conics, is a right line drawn on the vertical plane, and passing through the vertex of the cones.

VERTICAL DIAL, is a sun-dial drawn on the plane of a vertical circle, or perpendicular to the horizon.

VERTICAL POINT, in astronomy, the same with vertex or zenith.

VERTICILLATE PLANTS, are such as produce their flowers round the joints of the stalks in whorles; these are the same with the labiated or lipped flowers. All the plants producing flowers in this manner, belong to the didynamia class of Linnæus's system, and of the order gymnospermia: such are hyssop, mint, thyme, &c. See the articles DIDYNAMIA, GYMnospermia, &c.

VERTICITY, is that property of the loadstone, whereby it turns, or directs itself to some peculiar point. See MAGNET.

VERTIGO, in medicine, a disease in which the head seems to turn round.

This, according to Dr. Willis, is a disorder in which visible objects seem continually to turn round, whilst the patients are affected with a perturbation or confusion of the animal spirits in the brain, which

which hinders their influx into the nerves. Hence it is, that the visive and locomotive faculties often fail to such a degree, that the patient is ready to drop down, and complains of darkness.

Etmuller divides it into three kinds; the first of which is a simple vertigo, in which there is only a transient and short-continued gyration of objects. The second is a dark vertigo, or scotomia, when the eyes are darkened, or so affected, as if several colours were before them. The third is the vertigo caduca, in which the patient presently falls down.

A vertigo may be produced by every cause which can distend, press, or contract the arteries; such as sudden fear, surprize, ebriety, and voracity, by which the regular influx and reflux of the animal spirits into the optic nerves and retina are prevented. Sometimes, also, it may be produced by an acid, or any peccant humour, lodged in the stomach, and vellicating its nerves, which communicate with the retini; for which reason the hypochondriac and hysterical passions may produce a vertigo.

With respect to the cure, the regimen in general, ought to be the same with that in the apoplexy or epilepsy. See APOPLEXY and EPILEPSY.

If the patient is plethoric, a due quantity of blood is to be taken away; and if a nausea, loss of appetite, or any other disorder of the stomach remain, an emetic is to be prescribed; then cathartics and specifics are to be ordered.

According to Mayerne, calamus aromaticus, in whatever form, is good in a vertigo, and esteemed a secret for that disorder. The same author informs us, that a German physician cured a great many of vertigoes, by pills made of sugar of lead and Cyprus turpentine; four or five grains of which were to be taken for a dose, and their use persisted in for some days.

Glisson, as Bates informs us, after all other medicines had failed, was cured of a severe vertigo, of three weeks continuance, by shaving his head, and applying to it a plaster of the flowers of sulphur and whites of eggs. Some order a caustic, or a seton, to be applied to the back part of the neck; a cautery to the bregma, and Bates's epileptic electuary, or Fuller's Peruvian epileptic electuary, to be used internally.

Willis informs us, that after he had in vain tried all other medicines, he, with success, prescribed the following powder: Take of the powder of the roots of male piony, two ounces; of the flowers of male piony, one ounce; of peacocks dung, of the whitest kind, half a pound; and of white sugar, two ounces: reduce to a powder, the dose of which is to be about the quantity of a spoonful twice a day, drinking after it a draught of a decoction of sage and rosemary, impregnated with coffee.

Heister orders camphorated spirit of wine alone, or mixed with spirit of hartshorn, to be applied to

the top of the head and temples. And when the disorder proceeds from crudities in the stomach, he advises to prepare and dissolve them by neutral salts, that they may be afterwards evacuated by an emetic, or purge. After this, the patient should use stomachics and cephalics; as also a moderate quantity of wine at meals, which should be sparing. Pyramont-water is also said to be excellent in this case.

VERVIAN, *Verbena*, in botany. See the article VERBENA.

VERVIAN-MALLOW, in botany. See the article MALVA.

VERU-*Montanum*, in anatomy, a kind of little valve, in the place wherein the ejaculatory ducts enter the urethra.

Its use is to prevent the urine, in passing the urethra, from getting in at these ducts, and so mixing with the semen.

VERY LORD and VERY TENANT, are those that are immediate lord and tenant to one another.

VESICA, in anatomy, a bladder, a membranous or skinny part in which any humour is contained. See BLADDER.

VESICATORY, *Vesicatorium*, an external medicine, serving to raise a blister; whence, also, it is itself, though improperly, called a blister.

Vesicatories are unguents, cataplasms, or plasters, made of sharp irritating medicines, which have a faculty of drawing the humours from within, outwards, inflaming and ulcerating the skin, and raising vesicæ, or bladders, whence their denomination vesicatory.

We have vesicatories made of cantharides, euphorbium, figs, sublimate of mercury, lapis infernalis, mustard, anacardium, squills, briony, vinegar, pepper, leaven, which are incorporated and made up with honey, gums, resins, &c. to bring them to the consistence required.

VESICULA, vesicle, a diminutive of vesica, signifying a little bladder.

The lungs consist of vesiculæ, or lobules of vesiculæ, admitting air from the bronchia; and not only air, but also dust, &c.

There are several other parts in the body which bear this appellation; as the vesicula fellis, or gall-bladder, vesiculæ feminales, &c.

VESPA, the wasp, in zoology. See the article WASP.

VESPER, or HESPER, in astronomy. See the article HESPER.

VESPERS, in the church of Rome, denote the afternoon service, answering, in some measure, to the evening prayers of the church of England.

VESPERTILIO, the bat, in zoology, a genus of quadrupeds of the order of the feræ, the characters of which are these: the fore-teeth in the upper jaw are six in number, acute, and distant from each other;

other; the fore-teeth of the lower jaw are also fix, and acute, but contiguous: the canine teeth are two both above and below, on each side: the feet have each five toes; and the fore feet have the toes connected by a membrane, and expanded into a sort of wings, whereby it flies; whence this animal has been generally, but with the utmost impropriety, ranged among the birds.

The common bat is about the bigness of a mouse, and very much resembles it in shape and colour. There are several other species of this creature, some with, and others without, a tail.

**VESPERTILIONUM ALÆ**, bats-wings, in anatomy, a name given to the two broad ligaments which connect the bottom of the uterus to the bones of the ilium. See the article **UTERUS**.

**VESSEL**, *Vas*, denotes in general any thing for holding liquors; such are our domestic cups, pots, &c. as also the retorts, matrasses, crucibles, &c. of the chemists.

In anatomy, all the parts which contain or convey a fluid, are called vessels; as the veins, arteries, lymphatics, &c.

Some also extend the word vessel to the nerves, as supposing them the conduits of the animal spirits.

**VESSEL**, in navigation, a general name for all sorts of ships. See the article **SHIP**.

**VESTALIA**, in Roman antiquity, a festival celebrated in honour of the goddess Vesta, on the fifth of the ides of June; that is, on the ninth of that month.

**VESTALS**, *Vestales*, among the ancient Romans, were priestesses of the goddess Vesta, and had the perpetual fire committed to their charge: they were at first only four in number, but afterwards increased to six; and it does not appear, that their number ever exceeded six, among whom one was superior to the rest, and called *Vestalis maxima*.

The vestals were chosen from six to ten years of age, and obliged to strict continency for thirty years; the first ten of which were employed in learning the ceremonies of religion; the next ten in the performance of them, and the ten last in teaching them to the younger vestals.

The habit of the vestals consisted of an head-dress, called *infula*, which sat close to their heads, and from whence hung certain laces called *vittæ*; a kind of surplice made of white linen, and over it a purple mantle with a long train to it.

**VESTIBLE**, *Vestibulum*, in architecture, a kind of entrance into a large building; being an open place before the hall, or at the bottom of the staircase. Vestibles, intended for magnificence, are usually between the court and the garden.

The Romans had vestibles at the entrance of their houses, for sheltering those persons who were obliged to stand at the door; and we have now vestibles of

a like kind in many old churches, houses, &c. usually called porches.

The term vestibule is sometimes also used for a little anti-chamber, before the entrance of an ordinary apartment.

**VESTIBLE of the Ear**, in anatomy, a cavity forming the middle part of the labyrinth of the ear.

**VESTIGIA**, a Latin term frequently used, by English writers, for the traces or footsteps which any thing has left behind it.

**VESTRY**, a place adjoining to a church, where the vestments of the minister are kept; and also a meeting at such place, consisting of the minister, church-wardens, and chief men of most parishes, who make a parish vestry or meeting. By custom there are select vestries, being a certain number of persons chosen to have the government of the parish, make rates, and take the accounts of church-wardens, &c. And it is here to be observed, that when any rates are made, the parishioners must have notice of a vestry held for that purpose; in which case all that are absent shall be included by a majority of the parishioners present, who in construction of law are the whole parish. Vestries of parishes are to be consulted by parish officers; and if a parishioner, who has a right to be present and vote at a vestry, be shut out of the vestry-room, action of the case lies.

**VETCH**, *Vicia*, in botany. See the article **VICIA**.

**VETCH** also makes part of the English names of several other plants, as bitter vetch, chickling vetch, horse-shoe vetch, milk vetch, &c. See the articles **ERVUM**, **OROBUS**, **LATHYRUS**.

**VETERAN**, among the ancient Romans, an appellation given to a soldier who was grown old in the service, or had made a certain number of campaigns.

**VIA-LACTEA**, in astronomy, the milky-way, or galaxy. See **GALAXY**.

**VIA-SOLIS**, *the Sun's Way*, in astronomy, is used, among some astronomers, for the ecliptic line, so called, because the sun never goes out of it. See **ECLIPTIC**.

**VIÆ PRIMÆ**, first passages, among physicians, are the œsophagus, stomach, and guts; including the whole length of the alimentary duct, or canal, from the mouth to the sphincter ani.

**VIALES**, in mythology, a name given among the Romans to the gods who had the care and guard of the road and highways.

The *dii viales*, according to Labeo, were of the number of those gods called *dii animales*, who were supposed to be the souls of men changed into gods; and were of two kinds, viz. the *viales* and *penates*.

**VIATICUM**, in the church of Rome, an appellation given to the eucharist, when administered to persons at the point of death.

VIBEX,

**VIBEX**, is sometimes used, by physicians, for a black and blue spot in the skin, occasioned by an afflux or extravasation of the blood.

**VIBRATION**, in mechanics, a regular, reciprocal motion of a body, as a pendulum, &c. which being freely suspended, swings, or oscillates, first this way, then that.

**VIBRATION** is also used, in physics, for divers other regular alternate motions: thus sensation is supposed to be performed, by means of the vibratory motion of the nerves, begun by external objects, and propagated to the brain.

**VIBURNUM**, in botany, a genus of umbelliferous plants, whose flower is monopetalous, and campanulated, with the limb divided into five obtuse reflexed segments; the stamina are five subulated filaments, topped with roundish antheræ; the fruit is a roundish unilocular berry, containing one of-ferous roundish seed.

This genus comprehends the laurustinus, the opulus, or water-elder, the Virginian hawthorn, the guilder-rose, and the common viburnum or way-faring tree. See **LAURUSTINUS**, &c.

**VICAR**, *Vicarius*, a person appointed, as deputy to another, to perform his functions in his absence, and under his authority.

**VICAR**, in the canon law, denotes a priest of a parish, the predial tithes whereof are impropriated or appropriated; that is, belong either to a chapter, religious house, &c. or to a layman, who receives them, and only allows the vicar the small tithes or a convenient salary, anciently called *portio congrua*.

**VICAR-GENERAL**, was a title given by king Henry VIII. to Thomas Cromwell, earl of Essex, with full power to oversee the clergy, and regulate all matters relating to church affairs.

**VICE**, *Vitium*, in ethics, is ordinarily defined an elective habit, deviating either in excess or defect from the just medium wherein virtue is placed. See the articles **HABIT**, **VIRTUE**, &c.

**VICE**, in smithery, and other arts employed in metals, is a machine, or instrument, serving to hold fast any thing they are at work upon, whether it is to be filed, bent, rivetted, &c. To file square, it is absolutely necessary that the vice be placed perpendicular, with its chaps parallel to the work-bench.

*Hand-VICE*, is a small kind of vice serving to hold the lesser works in, that require often turning about.

Of these there are two kinds, the broad-chapped hand-vice, which is that commonly used; and the square nosed hand-vice, seldom used but for filing small round work.

**VICE**, is also a machine used by the glaziers, to turn or draw lead into flat rods, with grooves on each side to receive the edges of the glass.

**VICE**, is also used in the composition of divers words, to denote the relation of something that comes instead, or in the place, of another; as vice-admiral, vice-chamberlain, vice-chancellor, vice-president, &c. are officers who take place in the absence of admirals, &c.

**VICE-ROY**, a governor of a kingdom, who commands in the name and stead of a king, with full and sovereign authority.

**VICE VERSA**, a Latin phrase, importing, on the contrary; thus, as the sun mounts higher and higher above the horizon, the shadows of things decrease; and *vice versa*, as he descends lower, they increase.

**VICIA**, vetch, in botany, a genus of plants, whose flower is papilionaceous; the fruit is a long bivalve coriaceous pod, containing several roundish seeds.

To this genus belong the common tare. See the article **TARE**.

**VICISSITUDE**, the regular succession of one thing after another; as the vicissitude of day and night, of the seasons, &c.

**VICOUNT**, in old law-books, signifies the same with sheriff. See **SHERIFF**.

**VICOUNT**, or **VISCOUNT**, is also a degree of nobility next below a count, or earl, and above a baron. See **EARL**, &c.

**VICOUNTIEL**, in law-books, something belonging to, or falling within the sheriff's jurisdiction: thus writs vicountiels are writs triable in the sheriff's court; and there are certain vicountiel rents, whereof the sheriff keeps a particular roll, that usually comes under the title of *firma comitatus*.

Also vicountiel jurisdiction, is that which belongs to officers of a county; as sheriff, coroner, &c. See **SHERIFF**.

**VICTIM**, *Vidima*, denotes a bloody sacrifice offered to some deity, of a living creature, as a man or beast, which is slain to appease his wrath, or obtain some favour.

**VICTIMARIUS**, in antiquity, a minister or servant of the priest, whose office was to bind the victims, and prepare the water, knife, and other things necessary for the sacrifice.

To the victimarii it also belonged to knock down and kill the victims, in order to which they stood close by the altar naked to the waist, but crowned with laurel, and holding a hatchet or knife up, asked the priest leave to strike; saying, *agone?* whence they were called *agones* and *cultellarii*. See **AGON**.

When the victim was killed, they opened it, and after viewing the entrails, took them away, washed the carcase, sprinkled the flour on it, &c. The same victimarii lighted the fire wherein books were condemned to be burnt.

**VICTUALS**, signifies any kind of sustenance,  
2 or

or things necessary to live upon, as meat and provisions; which are to be sold at a reasonable price, assessed by justices, &c. on pain of forfeiting double the value. By the custom of some manors, they choose yearly surveyors of victuals.

**VILET ARMIS**, in law, are words made use of in indictments and actions of trespass, to shew the violent commission of any trespass or crime; but in an appeal of death, or where a person is killed with a weapon, these words are not held necessary, because the violence is implied.

**VIEW**, in law, signifies the particular act of viewings; as where a real action is brought, and the tenant does not certainly know what land it is the defendant requires; then he may pray that the jury may view the same, that is to say, see the land that is claimed. But it is held, that in all cases of viewing, the thing in controversy is only to be shewn to the jurors, and no evidence can be given relating to it on either side: and here if waste be alledged to be done, the view of the house generally is sufficient.

**VIEW of frank Pledge**, is the office which the sheriff in his county-court, the steward in the leet, or the bailiff in his hundred, performs in looking to the king's peace, and see that every man be in some pledge.

**VIGILS**, in church-history, are the fasts appointed before certain festivals, in order to prepare the mind for a due observation of the ensuing solemnity.

**VIGINTIVIRATE**, a tribunal or court among the ancient Romans, first established by Cæsar, consisting of twenty members, three of whom judged of all criminal matters; three others had the inspection of the coins; four others had the inspection of the streets of Rome; and the rest were judges of civil affairs.

**VILLAGE**, an assemblage of houses, inhabited chiefly by peasants and farmers, and having no market, whereby it is distinguished from a town.

Fleta tells us, that the difference made between a mansion, a village, and a manor, is this, viz. a mansion may consist of one or more houses, but must be of one dwelling place, and none near it; for if any other houses are contiguous, it is then a village; and a manor consists of several villages, or of one alone.

Where in legal proceedings a place is named generally, it shall be taken for a vill, because as to civil purposes the kingdom was first divided into vills; yet it has been held, that a vill and a parish shall be intended the same.

**VILLAIN**, or **VILLEIN**, *Villanus*, in our ancient customs, denotes a man of servile and base condition, viz. a bondman or servant: and there were anciently two sorts of bondmen or villains in England; the one termed a villain in gross, who was immediately bound to the person of his lord and his heirs; the other a villain regardant to a

manor, he being bound to his lord as a member belonging and annexed to the manor whereof the lord was owner; and he was properly a pure villain, of whom the lord took redemption to marry his daughter, and to make him free; and whom the lord might put out of his lands and tenements, goods and chattels at his will, and beat and chastise, but not maim him.

**VILLENAGE**, a kind of ancient tenure, whereby the tenant was bound to do such services as the lord commanded, or such as were fit for villains or bondmen to perform.

**VILLI**, among botanists, a kind of down like coarse hair, or the grain or shag of plush, with which some trees abound.

**VILLOSE**, or **VILLOUS**, something abounding with villi, or fibres like coarse hairs: such is one of the coats of the stomach. See **STOMACH**.

**VINCA**, periwinkle, in botany, a genus of plants, whose flower is monopetalous and saucer-shaped, with an horizontal limb divided into five obtuse segments; the stamina consists of five very short inflexed filaments, topped with erect, obtuse, membranaceous antheræ; the fruit consists of two erect cylindric husks opening longitudinally with one valve, and contains a number of oblong, cylindric, and furrowed seeds.

A species of this genus, which grows naturally on the island of Madagascar, is exceeding beautiful, and continues in full blossom all the summer, but being tender, requires a stove in this climate for its preservation.

This kind is easily propagated by cuttings in any of the summer months.

The common periwinkle grows wild among hedges, &c. in many parts of England; it has a fibrous root, with slender trailing stalks, furnished with oblong, ever-green leaves; it begins to flower in the spring, and continues a succession of blossoms for a long time.

It is said to be vulnerary, astringent, and febrifuge; and is given to abate all kinds of bleeding: the fresh leaves applied to the swellings of the king's evil, mixed with lint, are accounted by some an excellent remedy to disperse and dissolve them.

**VINCULUM**, in mathematics, a character in form of a line, or stroke, drawn over a factor, divisor, or dividend, when compounded of several letters or quantities, to connect them, and shew they are to be multiplied, or divided, &c. together by the other term. Thus  $d \times \frac{a+b-c}{a+b-c}$  shews that  $d$  is to be multiplied into  $a+b-c$ .

**VINDEMIATING**, the gathering of the grapes, or other ripe fruits, as the apples, pears, cherries, &c.

**VINDEMIATRIX**, or **VINDEMIATOR**, a fixed star of the third magnitude in the constellation Virgo. See **VIRGO**.

**VINDICATION**, or claiming, in the civil law,

an action arising from the property a person has in any thing; or a permission to take or seize a thing, as one's own, out of the hands of a person, whom the law has doomed not to be the true proprietor.

VINE, *Vitis*, in botany, a genus of plants, whose flowers are produced in bunches; the corolla of each consists of five small rude petals which drop off, and five subulated stamina; the fruit is a large, oval, or roundish berry, with one cell, containing five fleshy turbinate-cordated seeds.

Vines, so famous for the fruit and generous liquors they afford, are of various sorts, the principal of which are the July grape, the black sweet-water, the white sweet-water, the royal muscadine, the black cluster, the Burgundy, the white muscadine, the black frontinac, the white frontinac, the red frontinac, the red and black Hamburgh, and the St. Peter; these, with a few others, are the sorts most fit to be cultivated in this country, and in warm summers will ripen their fruit very well, particularly the seven first mentioned; they are all propagated by layers or cuttings; if from cuttings, they should be chosen from the last summer's shoots, well ripened, leaving a knob of the former year's wood to it; these may be taken off the mother plant either in autumn or spring, the autumn is the best season for this operation; their length may be about a foot in the ground, leaving two eyes or buds above. The best season to prune vines is when the leaves turn yellow and begin to drop off; the method to perform this, is to shorten the bearing shoots, which are those produced the last summer, to four or five buds, but if weak to three, these are sufficient; for each bud will produce a shoot which generally has two bunches of grapes, so that from each of those there may be expected six or eight bunches; these shoots should not be less than a foot distance, and if of the large kinds and vigorous, not less than a foot and a half asunder, the remaining wood to be cut away: in the training of vines against a wall, some direct them horizontally, and others perpendicular; it is not easy to determine which is best; if the wall is low, it may be proper to train them horizontally, but if high, the perpendicular direction should be preferred; for the vigorous nature of a vine is such, that though the branches are led up a wall eighteen or twenty feet high, yet the fruit at the top hath sufficient quantity of juices for its nourishment, and is not inferior to those bunches which grow within three or four feet of the ground.

In pruning a vine, observe to make the cut just above the eye, sloping it backward from it, and where it is convenient, to make choice of a fore-right bud to cut from, so that the slope will be next the wall, by which means the wound will not be so much exposed to the weather or sight.

For the management of vines in summer, observe that no kind of branch be suffered to grow as is not

fit and necessary either for wood or fruit; therefore in the beginning of May, all small weak shoots should be pulled off, these will put out in many places, and, if not displaced, rob the fruit of its nourishment: as the reserved shoots advance, they should be nailed up regularly; this practice should be done as often as it is necessary during the whole summer season, picking off all dangling shoots and lateral branches as they are produced. In July, the extremities of the fruit-bearing branches may be pinched off, this will help to strengthen and enlarge the bunches of fruit; but it is an ill practice to divest the branches of their leaves in order to admit the rays of the sun to the fruit; for being so suddenly exposed thereto, their skins will be so tough, as to prevent not only their growth but likewise their ripening.

It is absolutely necessary that strict regard be had to the summer management of vines, for on this depends the next year's success; so that a sufficient number of vigorous shoots be laid in to succeed such old ones as may be cut out in the autumn; and although vines will produce grapes from knots of old wood, yet they are never so good or large as those which grow on young vigorous branches.

If wines are planted against espaliers, the fruit (particularly the early sorts) will ripen very well in favourable seasons, especially if planted in a proper soil and good aspect, but such late grapes as the frontinac, &c. our summers rarely prove long or hot enough to bring them to the perfection they require, therefore it is necessary they should be under glass all the summer, whereby they will be completely ripened by September.

Before grapes begin to ripen, they should be carefully guarded against birds, wasps, and other insects, otherwise they will be destroyed in a short time; to prevent which, the vines should be carefully covered with nets, so as to exclude the birds, who make great havock with the grapes by breaking their skins; and if there are a few twigs covered with birdlime placed here and there on the outside of the nets, it will be of service, because the birds are often so bold as to attempt to break the nets to get at the grapes, which if they attempt, they may be so entangled on these twigs as not to get loose; and whenever that happens, they should not be disengaged, but suffered to remain, to deter their companions from offering such violences.

As to wasps, the best method is to hang up some phials about half filled with sugared or treacled water, into which they will get, without being able to return; these phials should be replenished every three or four days with fresh liquor, by which means the damage will be prevented.

The buds of the vine, as well as the leaves, are astringent, and they were used by the ancients to cure the looseness; some people in France now give the powder of the green leaves, dried in the shade,

to a dram, for the same purpose. The use of the fruit is universally known for eating or making wine. See the article WINE.

When the fruit is green, it produces the liquor which is properly called verjuice; and in this state it is a little astringent, and serves to abate the heat of the stomach and to stop a bilious looseness, as well as to recover the appetite; it is made use of in France in the same manner as our common verjuice made with crab-apples.

When grapes are dried in the sun or in an oven for keeping, they are called raisins of the sun. See the article RAISIN.

VINEGAR, *Acetum*, an acid penetrating liquor, prepared from wine, cyder, beer, &c. of considerable use both as a medicine and sauce.

The process of turning vegetable matters to vinegar, is thus delivered by Dr. Shaw: take the skins of raisins, after they have been used in making wine; and pour three or four times their own quantity of boiling water upon them, so as to make a thin aqueous mixture. Then set the containing cask, loosely covered, in a warmer place than is used for vinous fermentation; and the liquor in a few weeks time will become a clear and sound vinegar; which being drawn off from its sediment, and preserved in another cask, well stopped down, will continue perfect, and fit for use.

This experiment shews us a cheap and ready way of making vinegar from refuse materials; such as the husks of grapes, decayed raisins, the lees of wine, grounds of ale, beer, &c. which are frequently thrown away as useless. Thus, in many wine countries, the marc, rape, or dry pressing of grapes, are thrown in heaps, and suffered to putrify unregarded, though capable of affording as good vinegar as the wine itself. In some places they bury copper-plates in these husks, in order to make verdigrise; but this practice seems chiefly confined to the southern parts of France. Our present experiment shews us how to convert them to another use; and the direction extends to all the matters that have once undergone, or are fit to undergo, a vinous fermentation, for that all such matters will afford vinegar. Thus all our summer-fruits in England, even black-berries; all the refuse washings of a sugar-house, cyder-pressings, or the like, will make vinegar, by means of water, the open air, and warmth.

The whole process, whereby this change is effected, deserves to be attentively considered; and, first, the liquor to be thus changed, being kept warmer than in vinous fermentation, it begins, in a few days, to grow thick or turbid; and without throwing up bubbles, or making any considerable tumult, as happens in vinous fermentation, deposits a copious sediment.

The effect of this separation begins to appear,

first, on the surface of the liquor, which gathers a white skin, that daily increases in thickness, till at length it becomes like leather; and now, if continued longer in this state, the skin turns blue, or green, and would at last grow solid, and putrify: therefore, in keeping down this skin as it grows, and thrusting it gently down to the bottom of the vessel, consists much of the art of vinegar making, especially from malt. For the difference between vinous and acetous fermentation, see the article FERMENTATION.

*Method of making Cyder-VINEGAR.* The cyder (the meanest of which will serve the purpose) is first to be drawn off fine into another vessel, and a quantity of the must, or pouz of apples, to be added: the whole is set in the sun, if there be a conveniency for the purpose; and, at a week or nine days end, it may be drawn off. See CYDER.

*Method of making Beer-VINEGAR.* Take a middling sort of beer, indifferently well hopped; into which, when it has worked well, and is grown fine, put some rape, or husks of grapes, usually brought home for that purpose: mash them together in a tub; then, letting the rape settle, draw off the liquid part, put it into a cask, and set it in the sun as hot as may be (the bung being only covered with a tile, or slate-stone) and in about thirty or forty days, it will become a good vinegar, and may pass in use as well as that made of wine, if it be refined, and kept from turning musty.

Or thus: to every gallon of spring-water, add three pounds of Malaga-raisins; which put into an earthen jar, and place them where they may have the hottest sun from May till Michaelmas; then pressing all well, tun the liquor up in a very strong iron-hooped vessel, to prevent its bursting: it will appear very thick and muddy, when newly pressed; but will refine in the vessel, and be as clear as wine.

Thus let it remain untouched for three months, before it be drawn off, and it will prove excellent vinegar.

*Method of making Wine-VINEGAR.* Any sort of vinous liquor, being mixed with its own fæces, flowers, or ferment, and its tartar, first reduced to powder; or else with the acid and austere stalks of the vegetable from whence the wine was obtained, which hold a large proportion of tartar: and the whole being kept frequently stirring in a vessel which has formerly held vinegar, or set in a warm place full of the steams of the same, will begin to ferment a-new, conceive heat, grow sour by degrees, and soon turn into vinegar.

The remote subjects of acetous fermentation are the same with those of vinous; but the immediate subjects of it are all kinds of vegetable juices, after they have once undergone that fermentation which reduces them to wine: for it is absolutely impos-

sible

fible to make vinegar of must, the crude juice of grapes, or other ripe fruits, without the previous assistance of vinous fermentation.

The proper ferments for this operation, whereby vinegar is prepared, are, 1. The fæces of all acid wines. 2. The leys of vinegar. 3. Pulverised tartar, especially that of Rhenish wine, or the cream, or crystals thereof. 4. Vinegar itself. 5. A wooden vessel well drenched with vinegar, or one that has been long employed to contain it. 6. Wine that has often been mixed with its own fæces. 7. The twigs of vines, and the stalks of grapes, currants, cherries, and other vegetables of an acid austere taste. 8. Bakers leaven, after it is turned acid. 9. All manner of ferments, compounded of those already mentioned.

The French use a method of making vinegar different from that above described. They take two large oaken vessels, the larger the better, open at top; in each whereof they place a wooden grate, within a foot of the bottom: upon these grates they first lay twigs, or cuttings of vines, and afterwards the stalks of the bunches, without the grapes themselves, or their stones; till the whole pile reaches within a foot of the brim of the vessels: then they fill one of these vessels with wine to the very top, and half fill the other; and with liquor drawn out of the full vessel, fill up that which was only half full before; daily repeating the same operation, and pouring the liquor back from one vessel into another; so that each of them is full, and half full, by turns.

When this process has been continued for two or three days, a degree of heat will arise in the vessel, which is then but half full, and increase for several days successively, without any appearance of the like in the vessel which happens to be full, during those days; the liquor whereof will still remain cool: and as soon as the heat ceases in the vessel that is half full, the vinegar is prepared: which, in the summer, happens on the fourteenth or fifteenth day from the beginning; but in the winter, the fermentation proceeds much slower: so that they are obliged to forward it by artificial warmth, or the use of stoves.

When the weather is exceeding hot, the liquor ought to be poured off from the full vessel into the other twice a-day: otherwise, the liquor will be overheated, and the fermentation prove too strong; whence the spirituous parts will fly away, and leave a vapid wine, instead of a vinegar, behind.

The full vessel is always to be left open at the top, but the mouth of the other must be closed with a cover of wood, in order the better to keep down and fix the spirit in the body of the liquor; otherwise, it might easily fly off in the heat of fermentation. The vessel that is only half full seems to grow hot, rather than the other, because it contains a much greater quantity of the vine-twigs and stalks, than that, in proportion to the liquor; above

which the pile, rising to a considerable height, conceives heat the more, and so conveys it to the wine below.

Vinegar is a medicine of excellent use in all kinds of inflammatory and putrid disorders, either internal or external: in ardent bilious fevers, pestilential and other malignant distempers, it is recommended by Boerhaave as one of the most certain sudorifics. Weakness, fainting, vomiting, hysterical and hypochondriacal complaints have also been frequently relieved by vinegar applied to the mouth and nose, or received into the stomach. Distilled vinegar has the same virtues, only in a stronger degree.

There are also medicated vinegars, as vinegar of antimony, of elder, litharge, roses, squills, treacle, &c. which derive their chief virtues from the vinegar.

VINEYARD, *Vinetum*, a plantation of vines without the assistance of walls, &c. See VINE.

The best situation for a vineyard, is upon an elevation inclining to the south, with a small gradual descent; and the best soil for a vineyard, in England, is such whose surface is a light sandy loam, and not more than a foot and a half, or two feet, above gravel or chalk, either of which bottoms are equally good for vines; but clay or strong loams are not so proper for these plants, as the grapes produced on such lands are later in ripening, fuller of moisture, and consequently their juice not mature, nor well digested; therefore, very improper to make wine with.

The soil and situation being chosen, preparations previous to planting should be made; in doing which, the following method should be observed: In the spring, it should be ploughed as deep as the surface will admit, turning the sward into the bottom of each furrow; then it should be well harrowed to break the clods, and cleanse it from the roots of noxious weeds: and after this, it must be kept often plowed and harrowed, for at least a year, to render the surface light; and hereby it will become more fertile, by imbibing the nitrous particles of the air.

In March the ground should be well ploughed again, and after having made the surface pretty even, the rows should be marked out from south-east to north-west, at the distance of ten feet from each other, and these rows should be crossed again at five or six feet distance, which will mark out the exact places where each plant should stand, so that the vines will be ten feet row from row, and five or six feet asunder in the rows, nearer than which they ought never to be planted; for it has always been observed that the finest wines are produced from the fruit of those plants which have had the greatest distance allowed them.

The next thing to be considered is the choice of proper sorts of vines: those which produce the best wines are to be chosen, if cuttings are approved of, (which

(which are reckoned better than rooted plants) then make a hole about a foot deep in each cross mark; and in each hole should be placed one strong cutting, a little sloping; the hole should afterwards be filled up with earth, pressing it with the feet gently to the cutting, and raising a little hill of about three inches to each, so as just to cover the eye or bud, which will prevent the sun and wind from drying the cuttings, and this upper eye only will shoot, the under ones mostly will push out roots, so that this shoot will be very strong and vigorous.

After they are thus planted, they will require no other care till they shoot, except to keep the ground clear from weeds.

When the cuttings put forth, there should be a small stick, about three feet long, stuck down by each, to which the shoot should be fastened; and as they advance, the fastening should be renewed, and all small lateral shoots displaced, as they happen to be produced. In autumn, when the leaves decay, each shoot should be cut down to two eyes, and the earth drawn up to them for a defence against the frosts. In March, the ground should be dug between the vines; and, in May, two stakes should be fixed to the side of each, rather stouter than those used the preceding year, displacing all other small and lateral branches. In autumn, they are again to be pruned to three eyes; and in the succeeding year many of them will bear fruit.

The ground should be dug every year in the spring season, taking care, in the operation, not to cut or wound any of the main roots with the spade; but they should be cleared of all suckers which may happen to arise; and every autumn, the vines should be pruned to three or four eyes, and not to have above three shoots to each plant, which should be annually managed as directed under the article VINE; which see.

When the fruit is ripe, if the stalks of the bunches are cut half way through, a fortnight before they are gathered, it will cause the juice to be much better; as there will not be near so great a quantity of nourishment enter the fruit, whereby the watery particles will have time to evaporate, and the juice will be better digested: this is practised by the most curious vigneron in the south of France, where they make excellent wine.

As the beauty of vineyards arises from the regular disposition of the branches of the vines, great care should be taken in their management to train them regularly, and to provide every year for new wood to bear the succeeding summer; because the wood which has produced fruit, is commonly cut quite away after the fruit is gathered, or at least is shortened down to two eyes, to force out shoots for the next year, where there is not a sufficient number of branches upon the vine, of those trained upright; so that in summer, when the vines are in perfection, there should be six upright shoots trained for the

choice of next years wood, and three or four bearing branches with fruit, for more than these ought never to be on the vine.

**VINOUS**, *Vinosus*, something that relates to wine, or that has the taste and smell thereof.

All vegetables, by a due treatment, afford a vinous liquor, as corn, pulse, nuts, apples, grapes, &c. A second fermentation, duly managed, turns any vinous liquor into an acetous one. The proper character and effect of fermentation, are to produce either a vinous or an acetous quality in the body fermented. See FERMENTATION, WINE, and VINEGAR.

**VINTAGE**, a crop of wine, or what is got from the vines each season.

The word is also used for the time or season of gathering or pressing the grapes. See the articles WINE, &c.

**VINUM**, a liquor, or drink, commonly called wine. See the article WINE.

**VIOL**, *Viola*, a musical instrument of the same form with the violin, and struck like that with a bow.

There are viols of divers kinds; the first, and principal, among us, is the bass-viol, called by the Italians, *viola-digamba*, or the *leg-viol*, because held between the legs. It is the largest of all, and is mounted with six strings: its neck is divided in half notes by seven frets fixed thereon: its sound is very deep, soft, and agreeable.

The tablature, or music for the bass-viol, is laid down on six lines or rules. What the Italians call *alto viola*, is the counter-tenor of this; and their *tenore viola*, the tenor. They sometimes call it simply the viol: some authors will have it the *lyra*, others the *cithara*, others the *chelys*, and others the *testudo* of the ancients.

2. The *love-viol*, *viola d'amore*, which is a kind of triple-viol, or violin, having six brass or steel strings, like those of the harpsichord, ordinarily played with a bow. This yields a kind of silver sound which is very agreeable.

3. A large viol with forty-four strings, called by the Italians, *viola di bardone*, but little known among us.

4. *Viola bastarda*, or *bastard-viol* of the Italians; not used among us. Brossard takes it to be a kind of bass-viol, mounted with six or seven strings, and tuned as the common one.

5. What the Italians call *viola di braccio*, *arm-viol* (or simply, *braccio*, arm) is an instrument answering to our counter-tenor, treble, and fifth violin.

6. Their *viola prima*, or first viol, is really our counter-tenor violin; at least, they commonly use the cleff *C sol ut* on the first line, to denote the piece intended for this instrument.

7. *Viola secunda*, is much the same with our tenor-violin, having the cleff of *C sol ut* on the second line.

8. *Viola*

8. Viola terza, is nearly our fifth violin, the cliff *C sol ut* on the third line.

9. Viola quarta, or fourth viol, is not known in England or France, though we frequently find it mentioned in the Italian compositions; the cliff on the fourth line.

Lastly, their violetta, or little viol, is in reality our triple-viol, though strangers frequently confound the term with what has been said of the viola prima, secunda, &c. See VIOLIN.

VIOL, is also a term used among mariners, when a hawser, or strand-rope, is bound fast with nippers to the cable, and brought to the jeer-capstan, for the better weighing of the anchor when the main-capstan proves insufficient.

VIOLA, the violet, in botany. See VIOLET.

VIOLATION, the act of violating; that is, forcing a woman, or committing a rape upon her.

This term is also used, in a moral sense, for a breach or infringement of a law, ordinance, or the like; and it is also used for profanation. See the articles RAPE, &c.

VIOLENT, in the schools, a thing done by force: in which sense, it stands opposed to spontaneous. See SPONTANEOUS.

A thing is said to be violent when effected by some external principle, the body that undergoes it contributing nothing thereto, but struggling against it. The schoolmen allow, that man, as being endued with reason, is capable of suffering such violence, but bruté and inanimate bodies are not. See INANIMATE, &c.

VIOLET, *Viola*, in botany, a genus of plants, whose flower consists of five ringent irregular petals, with a corniculated nectarium at the base; the stamina are five small filaments, topped with obtuse antheræ, which are sometimes connected: the fruit is an ovate trigonal obtuse capsule, having one cell, which contains many ovate seeds.

The common sweet-scented violet is so well known as to need no description; it grows in gardens, in woods, and under hedges, in many parts of England, and is easily increased by parting the roots.

The leaves and flowers are used in medicine, and sometimes the roots; the flowers are a little purgative, and the syrup made of them is common, which, when well managed, is of a beautiful colour, and an useful laxative for children.

Bulbous VIOLET, in botany. See the article GALANTHUS.

Dames VIOLET, in botany. See the article HESPERIS.

VIOLIN, or FIDDLE, a musical instrument mounted with four strings, or guts, and struck or played with a bow.

The violin, like most other instruments, consists of three parts, the neck, the table, and the sound-

board. At the sides are two apertures, and sometimes a third is added towards the top, shaped like a heart. Its bridge, which is below the apertures, bears up the strings which are fastened to the two extremes of the instrument, at one end of them to a screw, which stretches or loosens them at pleasure.

The style and sound of the violin is the gayest, most lively, and sprightly, of all other instruments; and hence it is, of all others, the fittest for dancing: yet there are ways of touching it which render it grave, soft and languishing, and fit for church or chamber music. It generally makes the treble or highest parts in concerts. It is tuned by fifths: its play is composed of bass, counter-tenor, tenor, and treble: each part has four-fifths, which rise to a greater seventeenth. See the article FIFTH, &c.

In compositions of music the violin is denoted by V; two V V denote two violins. The word violin, alone, stands for treble violin. When the Italians prefix alto, tenore, or basso, it then expresses the counter-tenor, tenor, or bass violin. In compositions, where there are two, three, or more different violins, they make use of primo, secondo, terzo, or of the characters I<sup>o</sup>, II<sup>o</sup>, III<sup>o</sup>, or 1<sup>o</sup>, 2<sup>o</sup>, 3<sup>o</sup>, &c. to denote the difference.

The violin has only four strings, each of a different thickness; the smallest whereof makes the *e si mi* of the highest octave of the organ; the second, a fifth below the first, makes the *a mi la*; the third, a fifth below the second, is *d la re*; lastly, the fourth, a fifth below the third, is *ge re sol*. Most nations ordinarily use the cliff *ge re sol* on the second line, to denote the music for the violin only. In France they use the same cliff as the first line at bottom. The first of these methods is best where the song goes very low; the second, where it goes very high.

VIOLONCELLO of the Italians is properly our fifth violin; which is a little bass-violin, half the size of the common bass-violin, and its strings just half as thick and half as long, which renders the sound just an octave higher than the same.

VIOLONE, in music, a double bass, almost twice as big as the common bass-violin, and the strings bigger and longer in proportion, and consequently its sound an octave lower than that of our bass-violin, which has a noble effect in great concerts.

VIPER, in zoology, a species of coluber, with the scuta of the abdomen an hundred and forty-five, and the squammæ of the tail, thirty-six.

This is the most poisonous and mischievous in its bite of all the European serpents. It grows to near three feet in length, and to a considerable thickness in proportion. The principal ground colour of the body is a dusky grey; all along the back there runs a broad line, which is dentated on each side; and on each side of this there is a kind of bluish line, formed

VIRGO

formed of a series of spots of that colour, one of which is situated in the space formed by every denticulation in the back line: the belly is of a bluish black, very bright and glossy, resembling the colour of high polished, sanguined steel; and when closely examined, there is found a small dot of a deep black at the apex of every scale. The head is large and flattish; the throat is of a pale colour; and the mouth is large: the edge of the upper lip is whitish: the iris of the eye is of a flame colour; the pupil black; and there is a blue space, forming an acute angle, which separates the head from the longitudinal line on the back.

The poison of this serpent is confined to its mouth: at the basis of the phangs, or long teeth, which it wounds with, is lodged a little bag containing the poisonous liquid, a very minute portion of which mixed immediately with the blood, proves fatal. Our viper-catchers are said to prevent the mischiefs otherwise following from the bite, by rubbing oil-olive on the part. The flesh of the viper is perfectly innocent, and strongly recommended as a medicine of extraordinary service in scrophulous, leprous, and other chronical disorders: its virtues however in these cases, are probably too much exaggerated. The viper is undoubtedly a high nutritious food, and thence, in some kinds of weaknesses and emaciated habits, is not undeservedly looked on as a good restorative. To answer any valuable purposes, fresh vigorous vipers, not such as have been long kept alive after they are caught, should be liberally used as food. The wines and tinctures of them can scarce be supposed to receive any considerable virtue from the animal. The dry flesh brought us from abroad is entirely insignificant.

VIPER'S BUGLOSS, in botany. See the article ECHIUM.

VIPER'S GRASS. See SCORZONERA.

VIRGA, a yard. See YARD.

VIRGA is particularly used in law for a verge, or rod, such as sheriffs and bailiffs carry as a badge of their office.

VIRGÆ, in physiology, a meteor called also columellæ and funes tentorii; being an assemblage of several streams of light, representing a bundle of rods or ropes. It is supposed owing to the streaming of the sun's beams through certain rimulæ, or

chinks, at least through the more lax and open parts of a watery cloud, happening chiefly in the morning and evening. There is also another kind, consisting not of streams of mere white light, but, as it were, painted of various colours like those of the rainbow.

VIRGIN, *Virgo*, a female who has had no carnal commerce with man; or more properly, who has still the flos virginis or maidenhead.

VIRGIN is also applied figuratively to several things that retain their absolute purity, and have never been made use of. Thus virgin-wax is that which has never been wrought, but remains as it came out of the hive. Virgin-oil is that which oozes spontaneously out of the olive, &c. without pressing. Virgin-gold, is that metal such as it is found pure in the mine, without any mixture of alloy; in which state it is sometimes so soft that it will take the impression of a seal. Virgin-copper is a native copper found in the mine, and which has never been melted down. Virgin quick-silver is that found perfectly formed and fluid in the veins of mines; or at least such as is got from the mineral earth by mere lotion, without fire. Virgin-parchment is that made of the skin of an abortive lamb, &c. See the articles WAX, OIL, &c.

VIRGIN'S-BOWER, *Clematis*, in botany. See CLEMATIS.

VIRGIN'S-THREAD, a sort of meteor that flies in the air like small untwisted silk; which falling upon the ground, or upon plants, changes itself into a substance like a spider's web. In these northern climates it is most frequent in summer, the days being then temperately warm, the earth not exceeding dry, nor yet overcharged with moisture. This has formerly passed for a sort of dew of an earthy slimy nature: but naturalists are now agreed that the virgin's threads are no other than so many spiders webs. See the article SPIDER'S-WEB.

VIRGO, in astronomy, one of the signs, or constellations of the zodiac, into which the sun enters in the beginning of August.

The stars in the constellation Virgo, in Ptolemy's catalogue, are 32; in Tycho's, 39; in the Britannic, 89. The longitudes, latitudes, magnitudes, &c. of which, are as follow.

## Names and Situations of the Stars.

| Names and Situations of the Stars.      | Signs. | Longitude. | Latitude. |   | Magn. |

**VIRGULA DIVINA**, or **BACULUS DIVINATORIUS**, &c. a forked branch, in the form of a Y, cut off a hazle stick, by means whereof people have pretended to discover mines, springs, &c. under ground.

The method of using it is thus: the person who bears it, walking very slowly over the places where he suspects mines or springs may be, the effluvia exhaling from the metals, or vapour from the water, impregnating the wood, makes it dip or incline, which is the sign of a discovery.

Some dispute the matter of fact, and deny it to be possible. Others, convinced by the great number of experiments alledged in its behalf, look out for the natural causes thereof: the corpuscles (say those authors) rising from the springs or minerals, entering the rod, determine it to bow down, in order to render it parallel to the vertical lines which the effluvia describe in their rise.

**VIRGULTUM**, in our ancient law-books, is used for a holt or a plantation of twigs or osiers. See **OSIERS**.

**VIRILE**, something that belongs or is peculiar to a man, or the male sex: thus the virile member is used for the penis; virile age, the strength and vigour of a man's age, viz. from thirty to forty-five years, being the age wherein we are equally removed from the extremes of youth and of old age.

**VIRTUAL**, or **POTENTIAL**, something that has a power or virtue of acting or doing. The term is chiefly understood of something that acts by a secret invifible cause, in opposition to actual and sensible.

**VIRTUAL FOCUS**, in optics. See **FOCUS**.

**VIRTUALITY**, in the schools, denotes some mode or analogy in an object, which, in reality, is the same with some other mode, but, out of regard to contradictory predicates, is considered as if distinct therefrom.

**VIRTUALLY**, in the schools, is applied to a mode of existence. A thing is said to be virtually any where, when it is deemed to be there by some virtue, influence, or other effect, produced by it: thus the sun is virtually on earth, i. e. by his light, heat, &c. A thing is also said to be virtually present, when the virtues or properties belonging to it, and issuing from it, remain: in which sense the forms of the elements are held to be virtually in mixed bodies. A thing is said to be a cause virtually, or a virtual cause, and that two ways; the first, when there is no real distinction between it, and the effect attributed to it, and yet it is conceived by us, as if it were really the cause thereof: thus immutability in God, is the cause of eternity. Secondly, when an effect is not of the same kind with the cause, and yet the cause has the power or virtue of producing the effect; thus the sun is not formally but virtually hot; and the fire is not contained formally but virtually in heat.

**VIRTUE**, *Virtus*, a term used in various significations. In the general it denotes power, or perfection of any thing, whether natural or supernatural, animate or inanimate, essential or accessory. But in its more proper or restrained sense, virtue signifies an habit, which improves and perfects the possessor and his actions. See the article **HABIT**, &c.

In this sense virtue is a principle of acting or doing well and readily, and that either infused from above, such as are the theological virtues; or acquired by our own application, as the intellectual or moral virtues.

For as there are two things in man, from which all his actions proceed, viz. the understanding and the will; so the virtue by which he is perfected, or whereby he is disposed to do all things rightly, and to live happily, must be twofold: the one of the understanding, and the other of the will. That which improves the understanding is called intellectual, or dianoetic; and that, the will, moral and ethic; for since there are two things required, in order to live aright, viz. to know what should be done, and, when known, readily to perform it; and since man is apt to err various ways in each respect, unless regulated by discipline, &c. he alone can deport himself rightly in his whole course of life, whose understanding and will have obtained their utmost perfection.

Intellectual virtue, then, according to Aristotle, is an habit of the reasonable soul, whereby it conceives or speaks the truth, either in affirming or denying. The virtues which come under this class are divided into speculative, which are those conversant about necessary things, that can only be known or contemplated; and practical, which are conversant about contingent things, that may likewise be practised. Aristotle has another division of intellectual virtues, fetched from the subject, as some of them are seated in the contemplative part, viz. those conversant about necessary things, as science, wisdom, intelligence; and others in the practical part, such are those conversant about contingent things, as prudence, art, &c. See the article **SCIENCE**, &c. Moral virtue is defined, by Aristotle, to be an elective habit, placed in a mediocrity, determined by reason, and as a prudent man would determine. Moralists usually distinguish four principal, or, as they are vulgarly called, cardinal virtues, viz. prudence, justice, fortitude, and temperance: the reason of which division is founded in this, that for a man to live virtuously and honestly, it is necessary he know what is fit to be done, which is the business of prudence: that he have a constant and firm will to do what he judges best; which will perfect the man, either as it restrains too violent perturbations, the office of temperance; or as it spurs and urges on those that are too slow and languid, which

*Visions.*

is the business of fortitude; or, lastly, comparatively with regard to human society, which is the object of justice. To these four virtues all the rest are referred, either as parts, or concomitants. See the articles *PRUDENCE*, &c.

**VIRTUES**, in the celestial hierarchy, the third rank or choir of angels, being that in order between the denominations and powers: to these is attributed the power of working miracles, and of strengthening and reinforcing the inferior angels in the exercise of their functions.

**VIRTUOSO**, an Italian term lately introduced into English, signifying a man of curiosity and learning, or one who loves and promotes the arts and sciences; but among us the term seems to be appropriated to those who apply themselves to some curious and quaint, rather than immediately useful, art or study, as antiquaries, collectors of rarities of any kind, microscopical observers, &c.

**VIRULENT**, a term applied to any thing that yields a virus, that is a contagious or malignant pus.

**VIS**, a Latin word, signifying force or power, adopted by physical writers to express divers kinds of natural powers or faculties.

**VISCAGO**, in botany, the same with *silene*. See the article *SILENE*.

**VISCERA**, in anatomy, a term signifying the same with entrails, including the heart, liver, lungs, spleen, intestines, and other inward parts of the body.

**VISCIDITY**, or **VISCOSITY**, the quality of something that is viscid or viscous, that is, glutinous and sticky, like bird-lime, which the Latins call *viscus*.

Viscid bodies are those which consist of parts so implicated within each other, that they resist a long time a complete separation; and rather give way to the violence done them, by stretching or extending every way.

The too great viscosity of foods has very ill effects; thus meats, or *farinæ*, not fermented, gellies, &c. of animals, tough cheese, or curds too much pressed, produce a weight or oppression in the stomach, wind, yawnings, crudities, obstructions of the minuter vessels in the intestines, &c. Hence an inactivity of the intestines themselves, a swelling of the abdomen; and hence a viscosity of the blood, from the re-union of the viscid particles; obstructions of the glands; paleness, coldness, tremors, &c.

**VISCOUNT**. See *VICOUNT*.

**VISCUM**, misleto, in botany. See the article *MISLETO*.

**VISIBLE**, something that is an object of sight or vision, or something whereby the eye is affected, so as to produce a sensation.

**VISIER**, or **VIZIER**, an officer or dignitary in the Ottoman empire, whereof there are two kinds;

the first called by the Turks *visier-azem*, that is, grand visier, is the prime minister of state of the whole empire. He commands the army in chief, and presides in the divan or great council. Next to him are six other subordinate visiers, called visiers of the bench, who officiate as his counsellors, or assessors in the divan.

**VISION**, *Viso*, in optics, the act of seeing or perceiving external objects, by means of the organ of sight, the eye. See the article *EYE*.

Such is the substance and form of the humours of the eye, when lodged in their proper receptacles, that rays of light in passing through them, are affected in like manner as in passing through a convex lens; and therefore, to understand perfectly the nature of vision, we must first be acquainted with the doctrine of light and lenses. See *LIGHT* and *LENS*.

Now as the several pencils of rays flowing from the distinct points in the surface of an object placed before a lens, are collected into so many points at a certain distance on the other side of the lens, and form an image there, when received upon paper; so pencils of rays proceeding from an object placed before the eye at a proper distance from it, and being refracted in passing through the humours of it, are collected into their respective foci upon the retina, where they form a representation of that object; and by their impulses upon the tender nerves of the retina, an idea of the object is excited in the mind. See *REFRACTION*.

Vision is distinguished into bright and obscure, distinct and confused. It is said to be bright when a sufficient number of rays enter the pupil at the same time; and obscure, when too few: it is called distinct when each pencil of rays is collected into a focus exactly upon the retina; and confused, when they meet before they come at it, or when they would pass it before they meet.

Now since parallel rays only have their focus upon, or meet in, the retina, they alone can paint there a distinct image of an object, or produce a distinct vision of it. If, therefore, the object be so near, that the rays from any particular point come diverging to the pupil, they will necessarily require a greater focal distance than the retina or bottom of the eye; whence the rays not being united upon the retina, that point cannot be there distinctly represented, but will appear confused; thus, *AB*, *AB* (plate *XCII*. fig. 1.) are two parallel rays falling upon the pupil of the eye; and *CB*, *CB*, two other rays, which though really diverging, yet, by reason of the remoteness of the point *C*, whence they proceed, will at the entrance of the eye be so nearly coincident with the parallel rays, as to have nearly the same focal point on the retina, so that the point *C* will there be distinctly represented by *c*. But if any other point *E*, be viewed very near the eye, so that the angles *EBA*, which they contain

tain with the parallel rays, be very considerable, they will, after refraction tend towards the point  $f$ , in the axis of the eye produced, and upon the retina will represent only a circular indistinct area; like that at  $e$ , whose breadth is equal to  $ab$ , the distance of the rays upon the retina. The same point at  $D$ , will not be quite so much dilated, as the rays  $DB$ ,  $DB$ , have a less degree of divergence.

It is found by experience, that the nearest limit of distinct vision is about six inches from the eye; for if a book be held nearer to the eye than that, the letters and lines will immediately become confused and indistinct. Now this cause of indistinct vision may be in some measure remedied, by lessening the pupils, which we naturally do in looking at near objects, by contracting the annular fibres of the uvea; and artificially, by looking through a small hole made with a pin in a card, &c. for then a small print may be read much nearer than otherwise: the reason is plain, for the less the diameter of the aperture or pupil  $BB$ , the less will the rays diverge in coming from  $D$  or  $E$ , or the more nearly will they coincide with parallel rays.

Besides the contraction of the pupil, nature has furnished the eye with a faculty of adapting the conformation of the several parts to the respective positions of objects, as they are nigh or more remote; for this purpose the cornea is of an elastic yielding substance, and the crystalline is inclosed with a little water in its capsula, that by the contraction and relaxation of the ciliary ligament, the convexity of both the surfaces of the capsula may be a little altered, and perhaps the position of the crystalline; by which means the distance from the retina may be fitted and adjusted to nigh objects, so as to have their images very distinctly formed upon the retina.

Nigh objects only have been mentioned (by which are meant such as are near the limit of distinct vision, as between six and a hundred inches distance) because remoter objects require scarce any change of the conformation of the eye; the focal distance in them varying so very little. Thus, suppose all the refraction of the eye were equivalent to that of a double and equally convex lens, whose radius  $r=1$  inch: if then the object were 10 inches distant, or  $d=10$ , we should have the focal distance  $f=$

$$\frac{dr}{d-r} = \frac{1 \cdot 0}{9} = 0.11111; \text{ and if another object be distant}$$

$$100 \text{ inches, then } d=100, \text{ and } f = \frac{dr}{d-r} = \frac{1 \cdot 0}{99}$$

$= 0.0101$ . The difference between these two focal distances is  $0.0101$ , viz. the hundredth part of an inch, which the eye can easily provide against. If we go beyond this, suppose to an object 1000

inches distant, we have  $f = \frac{dr}{d-r} = 0.001001$ , which is only the thousandth part of an inch less than the former, and is therefore inconsiderable.

Now, rays proceeding from any point, more than 6 inches distant from the eye, will, when they enter the pupil, be very nearly coincident with parallel rays; and therefore, to a sound eye, distinct vision cannot be effected at less than 6 or 8 inches distance, as may be found by any one who will make the experiment.

Six inches, therefore, constitutes the limit of distinct vision, for near objects: we shall now consider the limit for remote objects; for objects may appear indistinct and confused, by being removed too far from the eye, as well as when they are too near it. And in this case, we find objects will appear distinct so long as their parts are separate and distinct in the image formed on the retina; and those parts will be separate so long as the axis of the pencils of rays, which paint them, are separate at their incidence on the retina; that is, so long as the angle they contain is not less than one-tenth of a degree; for it is found, by experience, that objects and their parts become indistinct, when the angle they subtend at the pupil of the eye is less than that quantity.

Thus, suppose  $OB$  (fig. 2.) to be a circle one-tenth of an inch in diameter, it will appear distinct with its central spot, till you recede to the distance of 6 feet from it, and then it becomes confused; and if it be one-fifth of an inch, it will begin to be confused at 12 feet distance, and so on; in which cases, the angle subtended at the eye, viz.  $OAB$ , is about one-tenth of a degree, or 6 minutes.

And thus all objects, as they are bigger, appear distinct at a greater distance; a small print will become confused at a less distance than a larger; and in a map of England, the names of places in small letters become first indistinct, where those in capitals are very plain and legible; at a bigger distance these become confused, while the several counties appear well defined to a much greater distance: these also at last become so indistinct as not to be known one from another, when at the same time the whole island preserves its form very distinctly to a great distance; which may be so far increased, that it also, at last, will appear but a confused and unmeaning spot.

We have seen the causes of indistinct vision in the objects, and shall now enquire what may produce the same in the eye itself.

And first it is to be observed, that there is a proper degree of convexity in the cornea  $KPL$  (fig. 3.) and crystalline  $ST$ , for converging parallel rays to a focus on the bottom of the eye, in a sound state; hence every distant object  $OB$ , will have its image  $IM$ , accurately depicted on the retina, and by that means produce distinct vision.

But if the cornea  $KPL$  (fig. 4.) or crystalline  $ST$ , or both, should chance to be a little more convex than just, it will cause the pencil of rays  $oCo$ , which comes to the pupil  $oo$ , from any point  $C$  in the object

ject  $OB$ , to unite in a focus before they arrive at the retina in the bottom of the eye; the image  $IM$ , of the object  $OB$ , will be formed in the body of the vitreous humour, and will therefore be very confused and indistinct on the retina at  $im$ . A person having such an eye, is called myops, in allusion to the eye of a mouse, by reason of its great convexity. To remedy this defect of the eye, a concave lens  $EF$ , is applied before it; for by this means the rays  $Ca$ ,  $Cb$ , which fall diverging on the lens, will, after reflection through it, be made to proceed still more diverging, *viz.* in the directions  $ar$ ,  $br$  (instead of  $ao$ ,  $bo$ ) as if they came from the point  $c$ , instead of  $C$ . Hence it follows, that since the rays are made to fall with greater divergence upon the eye, they will require a greater focal distance to be united in the axis; and, consequently, the focus may be made to fall very nicely on the retina, by using a lens  $EF$ , of a proper degree of concavity; so that distinct vision will be effected, in the same manner as in an eye of a just conformation.

Since the point  $c$ , is nearer to the eye than the point  $C$ , the apparent place of objects seen through a concave lens is nearer than the true place; or the object will appear at  $OB$ , instead of  $OB$ ; and also, since converging rays  $Ca$ ,  $Cb$ , proceed less converging after refraction than before, the object appears under a less angle; and, therefore, the apparent magnitude of objects, seen by a concave lens, is less than the true: the object is also less luminous or bright, seen thro' such a lens, than without it; because the rays being rendered more divergent, a less quantity enters the pupil of the eye, than otherwise would do: for the picture is always more or less bright, according as it is made by a greater or less quantity of rays. Lastly, it appears from what has been said, that when a concave lens  $EF$ , cannot be applied, we may still effect distinct vision, by lessening the distance between the object and the eye: for it is plain, if  $OB$  be situated at  $OB$ , the image  $IM$ , will recede to  $im$ , upon the retina, and be distinct, in the same manner as when made so by the lens  $EF$ .

On the other hand, when the cornea or crystalline is too flat, &c. (as often happens by age) an object  $OB$  (fig. 5.) placed at the same distance from the eye  $P$ , as before, will have the rays  $Ca$ ,  $Cb$ , after refraction in the eye, proceed to a focus beyond the bottom of the eye, in which, if a hole were made (in an eye taken out of the head) the rays would actually go on, and form the image  $im$ ; which image must, therefore, be very confused and indistinct on the retina. To remedy this defect, a convex lens  $GH$ , is applied, which causes the diverging rays  $Ca$ ,  $Cb$ , to fall less diverging upon the eye, or as if they came from a point more remote, as  $c$ ; by which means the focal distance is shortened, and the image duly formed on the retina at  $IM$ , by which distinct vision is produced.

Hence the apparent place of the object at  $c$ , is more distant than the true place is at  $C$ ; and its apparent magnitude  $OB$  is greater than the true, because the converging rays  $Ca$ ,  $Cb$ , are by this lens after refraction made to unite sooner than before, and so to contain an angle  $OPB$  greater than the true  $OPB$ . The object appears through a lens brighter than without, because by this means a greater quantity of rays enter the pupil; for the rays  $ao$ ,  $bo$ , are by the lens made to enter in the directions  $ar$ ,  $br$ , which are nearer together, and leave room for more to enter the pupil all around between  $o$  and  $r$ .

As the image of the object painted on the retina is greater or less, so will the apparent magnitude of the object be likewise; or, in other words, the angle  $IPM$  (fig. 6.) subtended by the image is always equal to the angle  $OPB$  subtended by the object at the eye, and therefore the image  $IM$  will be always proportionable to the object  $OB$ . Hence it follows, that the angle  $OPB$  under which an object appears, is the measure of its apparent magnitude.

Therefore objects of different magnitudes, as  $OB$ ,  $AC$ ,  $DE$ , which subtend the same angle at the eye, have the same apparent magnitude, or form an equal image in the bottom of the eye. Hence it is that objects at a great distance have their magnitude diminished proportionally; thus the object  $DE$  removed to  $DE$  appears under a less angle  $DP'E$ , and makes a less image on the retina, as is shewn by the dotted lines.

The angles of apparent magnitude  $OAB$ ,  $OCB$ , (fig. 7.) when very small, are as their sines, and therefore as the sides  $OC$  and  $OA$ , or  $BC$  and  $BA$ ; that is, the apparent magnitude of the object  $OB$ , at the distances  $BC$  and  $BA$ , is inversely as those distances; or its magnitude at  $C$  is to that at  $A$  as  $AB$  to  $CB$ .

The more directly any object is situated before the eye, the more distinctly it will appear; because those rays only which fall upon the eye near its axis can be convened to a point in the bottom of the eye on the retina, and therefore that part of the image only which is formed by the direct pencil of rays can be clear and distinct; and we are said to see an object by such a pencil of rays, but only to look at it by the others which are oblique. Suppose  $A$ ,  $B$ ,  $C$ , (fig. 8.) represent three pieces of paper stuck up against the wainscot of a room at the height of the eye; if then a person places himself so before them, and shutting his right eye views them with his left, it is very remarkable that the paper  $B$ , whose pencil of rays falls upon the insertion  $D$  of the optic nerve  $DE$ , will immediately vanish or disappear, while the two extreme papers  $C$  and  $A$  are visible; and by altering the position of the eye, and its distance, any of the papers may be made to vanish, by causing the pencil of rays to fall on the point  $D$ . Why the rays of light should not excite the sensation

tion of vision in the point D, where the fibres of the nerves begin to separate and expand every way to form the retina, is not easy to say. But it is worth notice, that the nerve DE is for that reason placed on one side of the eye, where only the oblique rays come, the loss of which is not considerable, and no way affects or hinders the perfection of sight: whereas had it entered in the middle of the bottom of the eye, it had rendered useless all the direct rays, by which the most perfect and distinct vision is effected; and we could have had only a confused and imperfect conception of objects, by oblique collateral rays.

The laws of vision, brought under mathematical demonstration, make the subject of optics, taken in the greatest latitude of the word; which is commonly used, in a more restrained sense, for the doctrine of direct or simple vision, performed by rays passing directly, or in a straight line, from the object to the eye. The doctrine of reflected vision, or that performed by means of rays reflected from mirrors, makes the subject of catoptrics; and refracted vision, or that performed by rays refracted through glass lenses, or other mediums, constitutes that branch of optics, called dioptrics.

VISION, among divines, an appearance which God occasionally sent his prophets and saints, either by way of dream, or reality: such were the visions of Ezekiel, Amos, St. Paul, &c.

*Beatific* VISION, denotes the act whereby the angels and blessed spirits see God in Paradise.

VISITATION, in law, an act of jurisdiction, whereby a superior, or proper officer, visits some corporation, college, church, or other public or private house, to see that the laws and regulations thereof be duly observed.

Among us, visitation is that office performed by the bishop in every diocese once in three years, or by the archdeacon every year, by visiting the churches and their rectors throughout the whole diocese, &c.

VISUAL, in general, something belonging to vision. See the article VISION.

Thus, rays of light, coming from an object to the eye, are called visual rays; and the visual point in perspective is a point in the horizontal line, wherein all the visual rays unite.

VITAL, in physiology, is an appellation given to whatever ministers principally to the constituting of life in the bodies of animals: thus, the heart, lungs, and brain are called vital parts; and those operations of these parts, whereby the life of animals is maintained, are called vital functions. See the article FUNCTION.

VITEX, the chaste-tree, in botany, a genus of plants, whose flower is monopetalous and ringent; the tube is cylindric and slender, the limb is plane and bilabiate, the upper lip is trifid, and the lower one divided into three segments; the middle laciniae of each is broadest: the fruit is a quadrilocular

globose berry, each cell containing an ovate seed. See AGNUS CASTUS.

VITIS, the vine, in botany. See the article VINE.

VITIS IDÆA, in botany. See the article VACCINIUM.

VITREOUS *humour of the eye*, is so called from its resemblance to glass in fusion, being very like a fine clear jelly in appearance: it probably, says Heister, consists of extremely fine vesicles, containing a limpid and perfectly pellucid humour. It fills the posterior part of the eye, and is every where contiguous to the hinder part of the retina, which it serves also to expand. See EYE.

VITRIFICATION, in chemistry, is the converting a body into glass, by means of fire. See the article GLASS.

Of all bodies, fern-ashes, sand, pebbles, &c. vitrify the most readily; and accordingly, it is of these that glass is principally made.

VITRIOL, in natural history, a compounded body formed of the particles of metals dissolved by the acid of sulphur, and that either by the operations of nature, within the earth, or in the chemists' laboratory by proper admixtures and assistances, and afterwards, by the help of water, brought into the form of a salt.

The vitriols, therefore, very much approach the nature of metals, and, in some instances, are found to have taken up other substances, particularly, some of the semi-metals among them, as, the white vitriol, which contains zink. See the article ZINK.

The other metals we find dissolved in this manner in the bowels of the earth, and there formed into vitriols, are iron and copper. These, therefore, are the great basis of those salts; and according as they belong to one or the other of them, are to be divided into the cupreous and the ferrugineous vitriols.

The naturalist who collects for his amusement, will meet with vitriols containing these two metals, in various proportions, in the same mass. The blue green vitriol of Hungary and Transylvania, and many other of the fossils of this class are of that kind.

We shall here only consider those vitriols fit for the use of medicine: and, therefore, treat of the distinct and determinate vitriols which contain only the particles of one of these metals. Of these there are but three kinds, viz. 1. Green vitriol. 2. White vitriol. 3. Blue vitriol. To these, however, we are to subjoin the vitriolic minerals, misy, sory, melantina, &c. which are all of them, properly, the ores of vitriols. See the articles MISY, SORY, &c.

1. Green vitriol has iron wholly for its basis. It is formed solely of that metal, dissolved by the acid of sulphur, and by means of water reduced to the form of salt. It is of two kinds, natural and factitious; the natural or native kind is known by the

the name of green vitriol; the common appellation of the other is copperas. See the article COPPERAS.

It is a tolerable pure and pellucid salt, of a compact and regular texture, considerably heavy, but friable, and easily shattering to pieces on the smallest blow. It is of a fine, pale, grass-green colour: it will not melt, or wholly run to water in a damp air, but it is very apt to be moist on the surface; it very readily dissolves in water, and after evaporation, freely shoots again into regular crystals, the true figure of which is a regular rhomboid; but they are seldom perfect or regular. Exposed to the fire, it becomes thin like water, boiling and bubbling up, and emitting a very thick fume. After this it grows thicker, and, finally, calcines to a grey powder; and from this, if the fire be continued and made more violent, to a fine purple matter, called calcothar of vitriol.

In England, where the greatest quantity of this vitriol is made, it is formed from the common greenish pyrites, with the addition of old iron. The people who collect these pyrites, are not at the pains of searching it among the strata, but they pick it up on the sea coasts of Essex, and other places, under cliffs, composed of strata of clay, out of which the sea washes it, and leaves it on the shore. This pyrites they expose to the air in vast heaps, and, in consequence of that, it by degrees begins to swell and burst, and shoot out in salts. They pile up these heaps in a kind of pits lined with clay, now and then turning them when their salt begins to appear in a downy efflorescence on the surfaces of the pieces they fall into, on breaking; the time of making vitriol being near.

These efflorescences dissolve by the rains and dews, and are, in fine, converted into an acrid liquor, which is conveyed from the bottom of the pits into leaden boilers, into which a quantity of old iron is also thrown; the fire is made under these, and the liquor is kept boiling for three days, or more, and is all the time supplied with fresh parcels of iron, so long as it will act upon them. The old iron, picked up by the poor people about our streets, is sold to the vitriol or copperas makers with this intent. When the liquor is boiled to a proper consistence, it is let out into large coolers, in which there are sticks placed across, to which, as well as to the sides of the vessel, the vitriol adheres in large crystals, of the form and texture above described.

This salt, on a chemical analysis, affords a very strong acid spirit; or, as it is usually, though very improperly, called, oil, which is a solvent for many of the metals, and effervesces very violently with an alkali, and even with spirit of wine, or common water. Mixed with sal armoniac, it ferments violently, but the fermentation is attended with great coldness, instead of the heat usual on these occasions;

and what is very singular is, that, while the fermenting mixture itself is thus cold, the vapour that arises from it is evidently hot to the hand. After the distillation of this acid liquor of vitriol, what remains in the retort is a red earth called colcothar; it contains iron, and is a strong astringent.

In medicine, this spirit is given internally in fevers and hæmorrhages, and particularly in malignant fevers of the petechial kind; to be taken in all the drink, in such quantity as to give an agreeable acidity to it.

Vitriolated tartar is another very valuable medicine, prepared from green vitriols, which attenuates the humours, resists putrefaction, and opens obstructions of the viscera. See TARTAR.

2. White vitriol is a true and genuine, though not a pure, vitriol of iron; the colour of which, that has so long perplexed the world to account for, is at length found to be owing to a mixture of zink in it.

The white vitriol, used in the shops, is all prepared from the native salt of the same name and colour, by solution and evaporation. It is a safe, gentle, and expeditious vomit; being given in solution, from ten grains to a scruple, or more: it is also used externally in collyriums, intended against inflammations of the eyes; and is a very powerful styptic in injections, to stop the gleet that sometimes remains after the cure of a gonorrhœa. See the article GONORRHOEA.

3. Blue vitriol is a vitriol which has copper for its basis. It is only met with suspended in the waters of certain springs, from which it is obtained by means of evaporation and crystallization. The water of such springs as are found strongly enough impregnated with copper to be worth the working for vitriol, is saved in reservoirs, and evaporated to a proper standard; after which, it is let out into coolers, where it shoots into the beautiful crystals we see; which have the same qualities with the water, and on solution in common water, they make a ziment-water, not to be distinguished from the native kind.

Blue vitriol is not given internally; but is of great use in external applications.

The blue vitriolic water of the shops, is made by dissolving three ounces of blue vitriol, and two ounces of alum, in a pint and a half of boiling water; and afterwards add two ounces of strong spirit of oil of vitriol, filtering the whole for use. It is an excellent styptic, and particularly serviceable in hæmorrhages of the nose. See the article HÆMORRHAGE.

VITRIOLATED, among chemists, something that has vitriol infused in it.

VITRIOLIC, an appellation given to whatever abounds with, or partakes of, the nature of vitriol: thus such fossil bodies as contain vitriol, are called vitriolic

vitriolic minerals, or ores of vitriol; as the pyrites, chalcitis, misy, sory, melanteria, marcasites, &c.

**VITUS'S DANCE**, *chorea sancti viti*, in medicine, a sort of convulsion, which boys and girls are subject to, from the age of ten years, to the time of puberty: it discovers itself first by a kind of lameness, or an instability of one of the legs, which they draw after them in a ridiculous manner; nor can they hold the arm of the same side still for a moment; and before they can bring a cup to their mouth, they use a thousand odd gesticulations. In a convulsive paroxysm, the limbs are strongly agitated; the hands are sometimes put behind them, and soon after they seem to be beating the air; and their legs will be drawn hither and thither, as if they were dancing some antic dance. See the articles **CONVULSION** and **SPASM**.

Dr. Mead thinks this disorder to be rather paralytic than convulsive, and that it may be cured by use of cold baths, and chalybeate medicines. Sydenham's method of cure is this: first take off seven or eight ounces of blood, more or less according to the strength of the patient, from the arm; and the next day, let the patient take a gentle purge of rhubarb, senna, manna, &c. In the evening of the same day, let him take a draught, with a scruple of Venice-treacle, and eight drops of liquid laudanum mixed in honey and milk-water. This purging and opiate draught is to be repeated at some days distance; the bleeding is also to be repeated to the fourth time; and in the intermediate days, a cordial and nervous electuary is to be given, composed of the conserves of rosemary, orange-peel, and Roman-wormwood, with Venice-treacle, candied nutmeg, and candied ginger; of this, the bigness of a nutmeg may be given every morning and afternoon, drinking after it a decoction of piony, masterwort, and elecampane, and angelica-roots, the leaves of rue, sage, betony, and other cephalic plants, with orange peel and Juniper berries. Spirit of harts-horn may also be given every night in small doses, in a nervous julep, and plasters of gum-caranna may be applied to the soles of the feet. According as the cure advances, the patient recovers the use of his hand and foot; and his amendment may always be discovered by letting him attempt to bring a glass of any liquor to his mouth in a strait line: though the bleeding should not be repeated beyond the fourth time, yet the alterative and purging medicines should be continued till the patient is quite well; and as people are subject to relapses in this disorder, it is proper to give the same medicines, and to bleed at the return of that season of the year.

**VIVA VOCE**, a Latin phrase frequently used in English writers, and literally signifying by word of mouth.

**VIVIFICATION**, in medicine, the art of vi-

vifying; that is of contributing to the action that gives life or maintains life.

**VIVIPAROUS**, *Viviparus*, in natural history, an epithet applied to such animals as bring forth their young alive and perfect, in contradistinction to them that lay eggs, which are called oviparous animals.

The females of all the quadruped class are viviparous, and those of the bird-class are all oviparous. The laws of nature in the larger animals, are therefore, in a great measure, fixed and certain; but it is not so in the insect tribes, nor in the fishes; for of these some are viviparous, and others oviparous; and those of genera nearly allied to one another. Among insects, the much greater number are oviparous; but there are many which are not so, as the pucerons, progallinsects, chochineal, &c.

The millepedes and scorpions are also well known to be so; all the females of the butterfly, and of some other classes, lay only eggs: but the most singular and remarkable inconsistency in nature, if we may be allowed the expression, is that in the fly-kingdom; the same class of insects, and even the same genus, will furnish us with some which are viviparous, and others which are oviparous; the two winged flies give us instances of this: but these are not single in that respect; for among the reptile world, there are other creatures which are subject to the same varieties; and Swammerdam has observed a viviparous snail. The two winged viviparous flies bring forth worms in all respects the same with those hatched from their eggs in the other species.

**VIVO**, in architecture, the shaft or fust of a column.

The term is also used in a more particular sense for the naked of a column, or other part.

**ULCER**, *Ulcus*, in surgery, is a solution of the soft parts of our bodies, together with the skin, produced by some internal cause, as an inflammation, abscess, or acrimonious humours. But wounds which become inveterate, and even contusions, when difficult of cure, come within this definition, and pass, at length, into ulcers, and are commonly so called. See **ABSCESS**.

The proper and usual seat of an ulcer, then, is in any of the softer parts of the body, as the skin, fat, glands, flesh, and internal viscera. For if there be any exulceration or corrosion in the harder parts, as the bones, it comes rather under the notion of a caries, or what is commonly called spina ventosa, than that of an ulcer; though, on account of some kind of resemblance which it has with the ulcer, or erosion, of the softer parts, they are sometimes treated of in conjunction. See the article **CARIES**, &c.

Ulcers can by no means be reckoned all of one kind.

kind, but are distinguished into various species, on many accounts; as, 1. with respect to the different parts of the body in which they are seated; for, sometimes they infest the skin, at other times the fat, and sometimes the glands and flesh. 2. As to their magnitude; for some ulcers are large and extended, others small, and contracted within narrow limits; some deep, others shallow and more superficial; in particular, ulcers of a considerable depth, but narrower, and more especially distinguished by the narrowness of their orifice or beginning, usually pass under the peculiar denomination sinus or fistula. Ulcers differ, 3. With regard to duration; for some are recent, others inveterate. 4. On account of their attendant symptoms; in which respect some ulcers are mild and favourable, others malignant, that is, attended with very acute pains, or foetid, putrid, pinguious, rheumy, or discharging much ichor, creeping or spreading, cancerous, or inclining to a cancer, callous, fistulous, or verminous; there is a difference between them. 5. With respect to their causes, in which light they assume the epithets of scorbutic, venereal, carious, cancerous, pestilential, and such as are supposed to proceed from fascination. In the last place, ulcers are distinguished by the parts in which they are seated. Thus, some infest the nostrils, others the fauces, palate, breasts, and anus; and one sort has the name of fistula lacrymalis. See the articles SINUS, FISTULA, &c.

The method of cure in ulcers is extremely various, as adapted to the great variety of the disease; for when the ulcer is but recent, it is to be healed in the same manner as a recent wound or abscess. We must first, then, begin with mundification, or cleansing the ulcer; after that proceed to incarn, or fill the cavity with new flesh; and, lastly, cover and conglutinate the same as much as possible, with a fair and even cicatrix.

Mundification of an ulcer is, according to Heister, usually performed in the following manner: first, the corrupted matter is evacuated; or, when it discharges itself not so freely as it ought, gently expressed with the fingers; if there be a deep sinus, belonging to the ulcer, it is to be extirped by some proper injections; or, if the place be open enough, by repeating intromissions of fresh lint. If there be any pieces of membranes, or other corrupted pinguious parts, left in the ulcer, the best way to eject them is, at every dressing, to introduce into the place lint moistened with some digestive ointment, and cover it with a plaster of diachylon, diapalma, or something of the like nature; and upon that, apply compresses, and over the whole a bandage: this method is to be carefully followed till the place be thoroughly cleansed, or till the bot-

tom of the ulcer appears quite red, and covered with new flesh.

After due mundification, the next business is to fill the ulcer with new flesh, which is performed by the help of such medicines as are commonly called farcotics.

The best and most effectual, by many degrees, is the digestive ointment; for without some extraordinary impediment, this digestive is, of itself, sufficient to produce new flesh. It is, indeed, the manner of almost all surgeons very gravely to recommend every one his proper balsamics for the procuring of new flesh; but it is presumed, there is no necessity for them to be so careful and solicitous in this point, since there is, in this very digestive, a balsamic virtue; and it ought, besides, to be considered, that this new flesh owes its generation, not so much to the assistance of medicines, as the benefit of nature: for all the care and diligence of the surgeon have scarce any other effect, than to remove all such things as are hurtful, and may prove impediments to a cure. If any one, however, should think this digestive ointment not strong enough for his purpose, he may try balsam of arcæus, balsam of Peru, balsam of Mecca, balsam of sulphur, essence of myrrh and aloes, oil of myrrh per deliquium, oil of eggs, and other vulnerary balsams of the like kind, which may be used in its stead; and, by the best means he can procure, to accomplish a perfect conglutination.

When an ulcer has penetrated so deep as to have its bottom remote, not only from sight, but from the reach of medicines, it may seem necessary in every dressing, after expressing the corrupted matter collected within, to make an injection of some cleansing and healing liquor; such as a decoction of agrimony and birthwort mixed with honey of roses, or essence of myrrh and aloes, or what Belloste, in his Hospital Surgeon, recommends, a decoction of walnut leaves mixed with sugar before the place be bound up, till the bottom is conglutinated, and to continue the same till the ulcer is filled up. See VULNERARY.

The ulcer being, by some means or other, as may seem most adviseable, incarnated and filled up, the induction of a fit and decent cicatrix must be completed; but if by such means you cannot prevent a luxuriance of flesh, with a moistness of the ulcer, it will be proper to sprinkle on the part some drying powders, such as those of mastic, frankincense, farcocolla, colophony, lapis calaminaris, and tutty; applying, afterwards, to the place dry lint, and a plaster accommodated to retain and hold together all the things applied, continuing the same till the place be perfectly whole and sound: but if the luxuriant and fungous flesh has already elevated it-

self above the rest, the best way to consume it, is to rub it with blue vitriol; or, if this be not strong enough, to sprinkle on it some powder of red precipitate and burnt alum, till its growth be entirely suppressed, and nothing appears prominent.

In the last place, it is hardly to be expressed how much a prudent regimen in diet and manner of living contributes towards the incuring and conglutination of ulcers: for it has been an old observation of the professors of the salutary art, that very bad ulcers have been cured by means of a regimen, without any considerable assistance from medicine; and, on the contrary, that the slightest and most contemptible sores have, by a neglect of the rules of diet, and preposterous way of living, degenerated into very bad, and even incurable, ulcers.

Great care, therefore, is to be taken by every person troubled with an ulcer, to avoid salt, acrid, and acid food, and such as is too fat or heating, with swine's flesh, and all such as is difficult of concoction. If a bad habit of body be an impediment to the cure of an ulcer, the advice of a skilful physician is required, who, by the prescription of proper internal medicines, may not only prevent an ulcer of a mild and favourable kind from becoming malignant, and perhaps incurable, but as much as possible promote and hasten its cure.

In callous and fistulous ulcers, that have formed variety of sinuses, and when either nothing can be done by corrosive medicines, or else that they tear and corrode the nerves, and bring on convulsions, and other bad symptoms, before they effect the callosus; in these cases, the best and safest way is to lay open the sinus, taking care not to wound the nerves, tendons and arteries. and, after that, all the callosities may be easily destroyed by the common methods. Or, if even this method should not have the desired effect, and if the patient has a considerable share both of strength and courage, and the situation of the nerves and arteries is favourable, the callous parts must be all entirely cut out with the knife, or burned away by the actual cautery. See the article CALLUS.

When ulcers are attended with a large discharge, the acrimonious serum, wherewith the blood abounds, should be evacuated by cathartic and diuretic medicines. Millepedes, in any form, are very properly prescribed to be taken internally in these, as are also essence of amber, myrrh, balsam of Peru, tincture of salt of tartar, tartarized tincture of antimony, and the like: large and frequent draughts of small liquors are frequently the cause of these disorders, and are therefore most carefully to be avoided; strong ale, or old wine, should be drank sparingly at meals, and nothing between them. Such meats are best, on these occasions, as have fewest juices in them, and are very well roasted; and the external medicines must be those which have the greatest reputation as dryers. The principal of these are

lime-water, lapis-calaminaris, tutty, chalk, mastic, frankincense, colophony, and native cinnabar; and and when any of these have been sprinkled in fine powder upon the ulcer, a plaster of diaphanophylos, or the like, is to be laid over it.

For the cleansing venereal ulcers, Heister recommends the phagedenic water; or lime-water, impregnated with calomel: either of these may be applied often every day, and the parts may also, if necessary, be touched with a caustic; and when they are thoroughly cleansed, they may very successfully be healed, either with an ointment made only with crude mercury mixed with turpentine, or with the following: take of the diaphanophylos ointment and crude mercury, killed with a small quantity of Venice-turpentine, of each equal quantities; mix them in a glass mortar into an ointment: or, take of the amalgama of lead and tin an ounce, of bole armenic two ounces; mix these, and make them into an ointment, by mixing with them a sufficient quantity of ointment of roses, or any other simple ointment, in a glass mortar. If there be at the same time a caries of the bone, which is, indeed, too frequently the case, this is to be dressed with euphorbium, oil of cloves, phagedenic-water, or spirit of nitre with quick-silver dissolved in it; or, if it can be conveniently and safely done, the actual cautery is of signal service.

ULCERATION, or EXULCERATION, in surgery, a little hole in the skin, caused by an ulcer.

ULEX, the furze, or whin-bush, in botany, a genus of plants, whose flower is pentapetalous and papilionaceous; the vexillum is almost heart-shaped, erect, large, and emarginated; the wings are short and obtuse, and the carina is dipetalous, obtuse, and join at their bottoms; the fruit is an oblong turged pod, having one cell and two valves, containing a few roundish emarginated seeds.

The common furze is so well known as to require no description; it may be raised from seeds, and will grow in any soil or situation, and is very useful for heating ovens, burning lime and bricks, and drying malt, where other fuel is scarce; it may be sown in such poor lands on which nothing else will grow, for the above purposes.

ULIGINOUS, in agriculture, an appellation given to a moist, moorish, and fenny soil.

ULLAGE, in gauging, is so much of a cask, or other vessel, as it wants of being full. See the article GAUGING.

ULMARIA, in botany, a species of filipendula. See the article FILIPENDULA.

ULMUS, the elm-tree, in botany. See the article ELM.

ULNA, in anatomy, one of the bones of the fore-arm, reaching from the elbow to the wrist: it is big at its upper extremity, and grows gradually smaller towards its lower end. See the article SKELETON.

This

This bone is longer than the radius, and has a motion of flexion and extension: at its upper extremity, it articulates with the os humeri and the crista of the radius; and its lower extremity articulates with the carpus, as also with the radius by means of a crista.

ULNA, an ell. See the article ELL and MEASURE.

ULNARIS, in anatomy, the name of two muscles of the carpus, or hand; one called ulnaris internus, which is a flexor muscle terminating in the internal office of the carpus; and the other, called ulnaris externus, is an extensor muscle, terminating in the metacarpal bone that supports the little finger.

ULTERIOR, in geography, is applied to some part of a country or province, which, with regard to the rest of that country, is situated on the farther side of the river, mountain, or other boundary, which divides the country into two parts. Thus Africa, with regard to Europe, is divided, by mount Atlas, into cterior and ulterior, i. e. into two portions, the one on this side mount Atlas, and the other on that.

ULTRAMARINE, *Ultramarinum*, a beautiful blue colour used by the painters, prepared from lapis lazuli, by calcination. See LAZULI.

The German lapis lazuli does not answer well in this process, and discovers itself by its calcining easier than the African or Asiatic, and turning greenish. The oriental kind calcines to a finer blue than it naturally has, and retains the colour for ever.

After calcining the stone in a clear fire of charcoal, they grind it to an impalpable powder on a porphyry, and then mixing it up in a paste, composed of pitch, wax, and oil, they work it about with the hands; and, finally, kneading this in a vessel of clear water, as the powder separates from the viscid matter, it sinks to the bottom: when all that is perfectly fine in this, is worked out, they let the water be drained off, and dry the powder for use. What remains embodied in the paste, is afterwards separated, and makes a worse kind than the former; though even the very meanest ultramarine is a very beautiful colour.

Ultramarine must be chosen of a high colour, and well ground, which may be known by putting it between the teeth, and if it feel gritty, it is a sign it has not been well ground.

To know whether it be pure and unmixed, put a little of it into a crucible, and heat it red hot; and if the powder has not changed its colour after this trial, it is certainly pure; on the contrary, if there be any change, or any black specks in it, then it has been adulterated.

There is also a spurious sort, called common or Dutch ultramarine; which is only small well ground and pulverized. See SMALT.

ULTRAMONTANE, something beyond the mountains. The term is principally used in relation to Italy and France, which are separated by the mountains of the Alps.

ULTRAMUNDANE, *Ultramundanus*, beyond the world; is that part of the universe supposed to be without, or beyond, the limits of our world, or system.

ULVA, in botany, a genus of water-plants, belonging to the cryptogamia class; the fructifications of which are disposed in membranous bladders, without the leaf.

UMBEL, *Umbella*, among botanists, is the extremity of a stalk or branch divided into several peduncles, or rays, beginning from the same point, and opening in such a manner as to form an inverted cone: these are either simple or compound; a simple umbel, is when the receptacle is but once divided into footstalks; but, a compound umbel, is when all the common footstalks are subdivided into umbellulæ, or little umbels. They are of different figures; as plane, convex, concave, or radiated.

UMBELLIFEROUS PLANTS, are those whose flowers are produced in an umbel, on the top of the stalks, somewhat representing an umbrella.

All the plants of this kind belong to the pentandria class of Linnæus; the flower is pentapetalous, and succeeded by two naked seeds, joined together. Those which grow wild in dry soils, are aromatic, warm, resolvent, and carminative; but those which grow in moist places are often poisonous, the virtue is chiefly in the roots and seeds; such are fennel, parsley, parsnips, carrots, hemlock, &c.

UMBER, or UMBRE, *Umbria*, among painters, &c. a kind of dry dusky-coloured earth, which, diluted with water, serves to make a dark brown colour, usually called with us, a hair colour.

It is called umber, from *umbra*, a shadow, as serving chiefly for the shading of objects; or, rather, from *Umbria*, a country of Italy, whence it is used to be brought.

UMBILICAL, among anatomists, something relating to the umbilicus, or navel. See the articles NAVEL and ABDOMEN.

UMBILICAL POINTS, in mathematics, the same with foci. See FOCUS.

UMBILICUS, the navel, in anatomy. See the article NAVEL.

UMBONE, a name used by some for the style or pistil of a flower. See the articles FLOWER, PISTIL, &c.

UMBRA, or SHADOW. See the article SHADOW.

UMBRE, or UMBER, among painters. See the article UMBER.

UMBRELLA-TREE, in botany, a curious species of magnolia. It grows in Carolina to the height of sixteen or eighteen feet; the trunk is slender, and the wood is soft and spongy; the leaves are large.

large, deciduous, and produced in horizontal circles, resembling an umbrella; whence the name: the flowers are composed of ten or eleven white petals, which hang down, and are afterwards succeeded by scarlet fruit, of the same form with the other species of magnolia, and is increased from seeds in the same manner. See MAGNOLIA.

UMPIRE, a third person chosen to decide a controversy left to arbitration. See the article ARBITRATION.

UNCIE, in algebra, the numbers prefixed before the letters of the members of any power produced from a binomial, residual, or multinomial root.

Thus, in the fourth power of  $a + b$ , viz.  $a^4 + 4a^3b + 6a^2b^2 + 4ab^3 + b^4$ , the uncies are 4, 6, 4; being the same with what others call co-efficients. See BINOMIAL, CO-EFFICIENT, and INVOLUTION.

UNCTION, *Unctio*, the act of anointing or rubbing with oil, or other fatty matter.

The cure of divers wounds, ulcers, &c. greatly depend upon repeated unctions with oil, unguents, cerats, &c. For the mercurial unction applied to bring on a salivation, see SALIVATION.

UNCTION, in matters of religion, is used for the character conferred on sacred things, by anointing them with oil.

Unctions were very frequent among the Hebrews. They anointed both their kings and high-priests at the ceremony of their inauguration. See INAUGURATION.

They also anointed their sacred vessels of the tabernacle and temple, to sanctify and consecrate them to the service of God. The unction of kings is supposed to be a ceremony introduced very late among the Christian princes. It is said, that none of the emperors were ever anointed before Justinian, or Justin. The emperors of Germany took the practice from those of the eastern empire: king Pepin of France was the first who received the unctions. In the ancient Christian church, unction always accompanied the ceremonies of baptism and confirmation.

Extreme unction, or the anointing persons in the agony of death, was also practised by the ancient Christians, in compliance with the precept of St. James, chap. v. ver. 14, 15; and this extreme unction the Romish church has advanced to the dignity of a sacrament. It is administered to none but such as are afflicted with some mortal disease, or are in a decrepit age. It is refused to impenitent persons, as also to criminals. The parts to be anointed are the eyes, the ears, the nostrils, the mouth, the hands, the feet, and the reins. The laity are anointed in the palms of the hands, but priests on the back of it; because the palms of their hands have been already consecrated by ordination. The parts

above-mentioned, are anointed in the form of a cross. The priest begins anointing the sick person's eyes, saying, "May God, by this holy anointing, pardon you the sins you have committed by the eyes." In like manner he proceeds to the other parts, varying the words according to the parts he anoints.

UNCUTH, unknown, is used, in the ancient Saxon laws, for him that comes to an inn guest-wife, and lies there but one night; in which case, his host is not bound to answer for any offence he committed, whereof he was guiltless himself. See HOGENHINE.

UNDECAGON, is a regular polygon, of eleven sides. See POLYGON.

UNDECEM VIR, a magistrate among the ancient Athenians, who had ten other colleagues or associates joined with him in the same commission.

UNDE, undee, or undy. See WAVY.

UNDER the Sea, in the sea language. A ship is said to be so when she lies still, or waits for some other ships, with her helm lashed, or tied up a-lee.

UNDER-CURRENTS, currents distinct from the upper or apparent currents of the seas.

Some naturalists conclude, that there are, in divers places, under-currents, which set or drive a contrary way from the upper current; whence they solve the remarkable phenomena of the sea's setting strongly through the Straights into the Mediterranean, with a constant current twenty leagues broad; as also, that running from the Euxine through the Bosphorus into the Hellespont, and thence into the Archipelago: they conjecture, that there is an under-current, whereby as great a quantity of water is carried out as comes in.

To confirm this, it is obtained, that between the north and south Foreland, it is either high or low water upon the shore three hours before it is so off at sea; a certain sign, that though the tide of flood runs aloft, yet the tide of ebb runs under foot, or close by the ground. Yet Dr. Halley solves the currents setting in at the Straights without overflowing the banks, from the great evaporation, without supposing any under-current. See the article SEA.

UNDERMINING, or SAPPING. See the article SAPPING.

UNDERSTANDING, *intellectus*, is defined by the peripatetics to be a faculty of the reasonable soul, conversant about intelligible things, considered as intelligible. They also make it twofold, viz. active and passive. Active understanding, they hold that faculty of the soul by which the species and images of intelligible things are framed, on occasion of the presence of phantasms or appearances thereof. For maintaining the intellect to be material, they hold it impossible it should be disposed to think by any disproportionable phantasms of mere body, and there-

therefore that it is obliged to frame other proportionate species of itself, and hence its denomination active.

Passive understanding, is that which receiving the species framed by the active understanding, breaks forth into actual knowledge. See the article KNOWLEDGE.

The moderns set aside the peripatetic notion of an active understanding. The Cartesians define the understanding to be that faculty whereby the mind conversing with, and, as it were, intent on itself, evidently knows what is true in any thing not exceeding its capacity. The corpuscular philosophers define the understanding to be a faculty expressive of things which strike on the external senses, either by their images or their effects, and so enter the mind. Their doctrine is, *nihil esse in intellectu quod non prius fuerit in sensu*; and to this doctrine Mr. Locke, and most of the latest English philosophers, subscribe. See IDEA.

Between the Cartesians and corpuscularians there is this farther difference, that the latter make the judgment to belong to the understanding, but the former to the will. Hence, according to the most approved opinion of the corpuscularians, the understanding has two offices, viz. perception and judgment; according to the Cartesians, it has only one, viz. perception. See the articles PERCEPTION, JUDGMENT, and WILL.

UNDERSTANDING is also used for the act, exercise, or exertion, of this faculty, or the action whereby the mind knows things, or represents them in idea to itself.

UNDERWOOD, *Sub-bosus*, is coppice, or any wood that is not accounted timber. See the articles COPPICE and TIMBER.

In the cutting the underwood of coppices, when the stubbles are great, they should be stubbed up; for they only take up a great deal of room, and send up few shoots, their cracks and holes letting in water, and usually half killing them. The taking up these should be performed in winter, and the spaces they leave will be occupied by young trees: if not, a long branch of some neighbouring tree may be laid down, which will soon send up a sufficient supply of suckers for the place. In felling the underwood, it is always proper to leave young trees enough, the worst of which may be taken down the next fall, especially if any of them grow near a great tree that will be fit to fell the next season, because they may be spoiled by its fall.

UNDULATION, in physics, a kind of tremulous motion or vibration observable in a liquid, whereby it alternately rises and falls like the waves of the sea.

This undulatory motion, if the liquid be smooth and at rest, is propagated in concentric circles, as most people have observed upon throwing a stone, or other matter, upon the surface of a stagnant wa-

ter, or even upon touching the surface of the water lightly with the finger, or the like. The reason of these circular undulations is, that by touching the surface with your finger, there is produced a depression of the water in the place of contact. By this depression, the subjacent parts are moved successively out of their place, and the other adjacent parts thrust upwards, which lying successively on the descending liquid, follow it; and thus the parts of the liquid are alternately raised and depressed, and that circularly. When a stone is thrown into the liquid, the reciprocal vibrations are more conspicuous: here the water, in the place of immersion, rising higher by means of the impulse, or rebound, till it comes to fall again, gives an impulse to the adjoining liquid, by which means that is likewise raised about the place of the stone as about a center, and forms the first undulous circle; this falling again, gives another impulse to the fluid next to it, farther from the center, which rises likewise in a circle; and thus successively greater and greater circles are produced.

Undulatory motion is likewise applied to a motion in the air, whereby its parts are agitated after the like manner as waves in the sea; as is supposed to be the case when the string of a musical instrument is struck. This undulatory motion of the air is supposed the matter or cause of sound.

UNGELD, in our ancient customs, a person out of the protection of the law; so that if he were murdered, no geld or fine was to be paid, in the way of compensation, by him that killed him.

UNGUENT, or OINTMENT, *Unguentum*, in medicine and surgery, a topical remedy or composition, chiefly used in the dressing of wounds and ulcers.

Unguents are divided into simple and compound, though it so happens that some of the former are considerably compounded; and amongst the latter there are some simple unguents, and others very little compounded. Unguents, liniments, and cerates, are external forms applied on divers parts of the body, both to cure, to ease, and to relieve them. These only differ from each other in their consistence; with regard to which, unguents hold the medium, being stiffer than liniments, but softer than cerates. Oils are the bases of all the three, to which are added wax *axungia*, and several parts of plants, animals, and minerals, both on account of the virtues they furnish, and to give a consistence to the oils, and to keep them longer on the part, that they may have more time to act. See CERATE and LINIMENT.

Any of the officinal plasters, diluted with so much oil as will reduce it to the thickness of stiff honey, forms an ointment; by further increasing the oil it becomes a liniment.

There are some considerable compositions of this form in the intention of emollients: and amongst

the compound unguents there are some which take in a number of very warm aromatic ingredients, and seem designed for paralytic infirmities, and cases that require brisk attenuating applications. At the head of the emollient unguents, is the unguentum dialthææ; and among the attenuating ones, the most in esteem is the unguentum martiatum and nervinum. There are ointments also within the intention of strengtheners: and the next intention of any consequence for which we are provided by this form, and which seems as suitable to it as any, is against cutaneous foulnesses, as the itch, and such like distempers; and this seems to be the reason that there is such a choice of them now given. But though most of these have the reputation of great antiquity, and hold their places in abundance of officinal dispensaries down to the present, yet they are so uncleanly in use, that they are almost altogether fallen into neglect, unless in some of our hospitals; those which contain mercury being much more neat and efficacious for the same purpose.

Some other things of this division are little else than oils wrought into ointments, by the exchange of oil for lard. Pomatums are also ranked among the number of unguents. See POMATUM.

UNGUIS, a Latin term, signifying a nail of the hand or foot. See NAIL.

UNGUIS, PANNUS, or PTERYGIUM, in medicine and surgery, a preternatural membrane formed upon the coats of the eye, so as to extend itself over the cornea and pupil, and obstruct the sight.

An unguis of the eye happens when the blood-vessels of the tendinous tunic in the corners of the eyes are turgid with blood, through an obstruction or inflammation. When this distemper increases, there is a sort of carnosous web which covers the eye in whole or in part, insomuch that the eyes are offended with the light, and look red sometimes: the web is thin and white, sometimes thicker and more fleshy, rough, obscure, and painful; nay, sometimes it becomes cancerous, which is incurable, and ought not to be touched.

In the cure, this preternatural coat is to be removed, or taken off, by abstergent and gently corroding medicines, or by the hand of a surgeon. The medicines in use are sugar-candy, honey, white-wine, bone of the cuttle-fish, burnt hartshorn, and calcined egg-shells; as also water of eye-bright, the greatcelandine, and the fennel, in which crocus metallorum may be infused: particularly the gall of pike dissolved in a proper water; that is, two ounces to one of the gall. Some recommend a water distilled from the dung of young geese in April.

If the disorder be obstinate, the juice of the greatercelandine may be used diluted in fennel-water. The following collyrium is proper: Take of prepared lapis hæmatitis, half a scruple; of white vitriol, twenty-five grains; of myrrh and saffron, each five

grains; of white-sugar candied, one scruple. Reduce this mixture to a powder, and then mix it with equal parts of waters of roses, eye-bright, and fennel, and apply it to the eye with a feather, taking care not to injure the pupil.

UNGUIS, in anatomy, is applied to two bones of the nose, being as thin as scales, and resembling the nail; whence their name. The unguis are the smallest bones in the upper jaw, and are situated near the great canthus of the eyes. Some authors call them ossa lacrymalis; others, orbitaria-ossa. They are contiguous to four other bones, viz. the coronal; that of the nose; the maxillary; and that part of the ethmoides which forms the orbit.

UNGUIS, among botanists, the narrow part of a petal, which is inserted in the receptacle, and is generally hid by the cup; the broader part towards the end is called bractea; such are the petals of carnations, &c.

UNGUIS ODORATUS, the nail-like sweet shell, in pharmacy, a medicine famous among the ancients; but has, for a long time, been out of credit: and the consequence of the neglect that has been shewn it is the losing its real history, and the mistaking different substances of the same origin and nature, though the produce of different animals, for it.

UNGULA, in geometry, the section of a cylinder cut off by a plane passing obliquely through the plane of the base and part of the cylindric surface.

UNGULA, in natural history, the claw or hoof of a quadruped.

UNICORN, *μονοκερως*, an animal, famous among the ancients, but looked on by the moderns as fabulous, denominated from its distinguishing characteristic of having one horn only, which is represented as five palms long, and growing in the middle of the forehead. It is said to be about the size of an horse: its hair short, and of a darkish brown colour, very timorous, and therefore keeping mostly in the woods. Some will have it an amphibious animal, and its horn moveable at pleasure. Others make all its strength to consist in its horn; and add, that when pursued by the hunters, it precipitates itself from the top of the highest rocks, and pitches upon its horn, which sustains the whole effort of its fall, so that it receives no damage thereby. It is added, that it is wonderfully fond of chaste persons; and therefore, in order to take it, a virgin is placed in its way, whom, when the unicorn spies, he lies down by her, lays his head in her lap, and falls asleep; upon which, the virgin making a signal, the hunters come in and take the beast; which could never be caught by any other means, because it would either cast itself from a rock or die.

UNICORN-FISH, in ichthyology, a species of the monodon, or narwal, an extremely singular fish; the length of a full-grown one being about twenty-five

five feet, but commonly from sixteen to twenty: it has only one tooth, remarkably long, which is fixed in the upper jaw, and runs parallel with the length of the fish, so that it has more the appearance of a horn than a tooth.

The diameter of this fish equals at least half its length, whence it is very unwealdy: the head is small, and shaped like that of a roach: there is no fin on the back; and the fistule is in the vertex or uppermost part of the head. The tooth grows to ten feet or more in length, is about the thickness of a man's wrist towards the base, and thence becomes gradually smaller all the way to the point.

**UNICORNU**, *Fossile Unicorn's Horn*, the name of a substance much used in medicine in some parts of the world, and, which seems to have been very little understood by many who have written of it; but is now determined to be no other than a terrene crustaceous spar, not very different from the osteocolla, and other bodies of that genus called the cibdeloplacium.

It is esteemed as a sudorific and astringent, and is given in fevers attended with diarrhoeas, with great success. See the articles **CIBDELOPLACIA** and **OSTEOCOLLA**.

**UNIFORM**, denotes a thing to be similar, or consistent, either with another thing or with itself, in respect of figure, structure, proportion, and the like; in which sense it stands opposed to difform. See the article **DIFFORM**.

Thus the uniform flowers of plants, are such as are of the same figure all around, having their fore and back parts, as also their right and left parts, exactly alike.

**UNIFORM MOTION**, &c. See the articles **MOTION** and **EQUABLE**.

**UNIFORMITY**, a similitude, or resemblance, between the parts of a whole; such is that we meet with in figures of many sides and angles respectively equal, and answerable to each other.

**UNIOLA**, in botany, a genus of plants, whose flower consists of a bivalvular glume, or husk; each valve is of a lanceolato-compressed figure, like those of the cup; the inner valve appears somewhat higher than the outer one: the stamina are three capillary filaments, topped with oblong linear antheræ: there is no pericarpium, but the corolla incloses the seed, which is single, and of an ovato-oblong figure.

**UNION**, a junction, coalition, or assemblage of two or more different things in one.

**UNION**, among painters, expresses a symmetry and agreement between the several parts of a painting; e. g. when there is a great deal of relation and connection between them, both as to the figuring and colouring; so that they apparently conspire to form one thing.

**UNION**, in an ecclesiastical sense, denotes a com-

bining or consolidating of two churches into one: There are two kinds of this union, as when one church is made subject to another, and one parson is made rector of both; and where a conventual church is made a cathedral.

In case two churches were so small as that the tythes did not make a competent provision for each of the parsons, they might be united at common law before any act of parliament was made for that purpose.

By statute, there may be an union of two churches where they lie not above a mile distant from each other, and where the value of the one exceeds not six pounds a year in the king's books of first fruits; which is done by the consent of the bishop, the patron, and incumbent.

Also, in cities or corporate towns, it is ordained, that the bishop, the patron, and the mayors, or chief magistrate of the place, &c. may unite parish-churches therein: yet, when the income of the church is above one hundred pounds per ann. there the major part of the parishioners are to agree to the same; and after the union, the patrons of those churches are to present by turns, &c. but, notwithstanding, each of the parishes continue distinct as to rates, charges, &c.

**UNION**, or the **UNION**, by way of eminence, is more particularly used to express the act whereby the two separate kingdoms of England and Scotland were incorporated into one, under the title of the kingdom of Great-Britain. This happy union, in vain attempted by king James I. was at length effected in the year 1707, by the general consent of the queen and the estates of each realm. The chief articles of this union are, That the two kingdoms shall be united into one kingdom, by the name of Great-Britain: that they, in consequence thereof, be represented by one parliament, of which sixteen peers and forty-five commoners are to be elected for Scotland, and have the same privileges with those of England: that the subjects of either nation shall have equal freedom of trade, and be liable to the same customs, and the like laws for public government, &c.

The kirk, or church of Scotland, is confirmed; and the courts of justice are to remain the same as they were before the union, yet subject to regulation, &c.

A court of exchequer is also erected in Scotland, to be a court of record, revenue, and judicature forever; and barons of the said court are appointed, who shall be the judges there, &c.

**UNISON**, in music, the effect of two sounds which are equal in degree of tune, or in point of gravity and acuteness.

Unison may be defined a consonance of two sounds produced by two strings, or other bodies, of the same matter, length, thickness, tension, &c.

equally struck, and at the same time : so that they yield the same tone or sound. See SOUND.

Unison is the first and greatest of concords, and the foundation of all the rest, according to Aristoxenus and most of the ancients : yet some deny it to be any concord at all, maintaining it to be only that in sounds which unity is in numbers.

Others refrain the word concord to intervals, and make it include a difference of tune ; but this is precarious : for as the word concord signifies an agreement of sounds, it is certainly applicable to unisons of the first degree.

But though unisonance, or an equality of tune, makes the most perfect agreement of sound, it is not true, that the nearer any two sounds come to an equality of tune, they are the more agreeable. The mind is delighted with variety ; and the reason of the agreeableness or disagreeableness of two sounds must be ascribed to some other cause than the quality or inequality of the number of their vibrations. It is a famed phenomenon in music, that an intense sound being raised, either with the voice or sonorous body, another sonorous body near it, whose tune is either unison or octave to that sound, will sound its proper note, unison or octave, to the given note. The experiment is easily tried by the strings of two instruments, or by a voice and harpsichord ; or a bell, or even a drinking-glass.

This our philosophers account for thus : one string being struck, and the air put in motion thereby, every other string, within the reach of that motion, will receive some impression therefrom : but each string can only move with a determined velocity of recourses or vibrations ; and all unisons proceed from equal or equidiurnal vibrations ; and other concords, from other proportions. The unison string then, keeping equal pace with the sounding string, as having the same measure of vibrations, must have its motion continued, and still improved, till its motion become sensible, and it gives a distinct sound. Other concurring strings have their motion propagated in different degrees, according to the frequency of the coincidence of their vibrations, with those of the sounded string ; the octave therefore, most sensibly : then in the fifth ; after which the crossing of the motions prevents any effect.

This they illustrate by the pendulum, which, being set a moving, the motion may be continued, and still improved, and augmented, by making frequent, light, coincident impulses ; as blowing on it when the vibration is just finished : but if touched by any cross or opposite motion, and this too frequently, the motion will be interrupted and cease altogether.

So of two unison-strings, if the one be forcibly struck, it communicates motion by the air to the other : and being equidiurnal in their vibrations, that is, finishing them precisely together, the mo-

tion of the other will be improved and heightened by the frequent impulses received from the vibrations of the first ; because given precisely, when that other has finished its vibration and is ready to return : but if the vibration of the chords be unequal in duration, there will be a crossing of motions less or more, according to the proportion of the inequality ; by which means the motion of the untouched string will be so checked as never to be sensible. And this, we find, is the case in all consonances, except unison, octave, and the fifth.

UNIT, UNITE, or UNITY, in arithmetic, the number one, or one single individual part of discrete quantity.

UNITY, in poetry. In the drama there are three unities to be observed, viz. the unity of action, that of time, and that of place. In the epic poem, the great, and almost only, unity, is that of the action. Some regard, indeed, ought to be had to that of time ; that of place there is no room for. The unity of character is not reckoned among the unities. See the article EPIC, &c.

The unity of the dramatic action consists of the unity of the intrigue in comedy, and that of the danger in tragedy ; and this not only in the plan of the fable, but also in the fable extended and filled with episodes.

The episodes are to be worked in without corrupting the unity, or forming a double action ; and the several members are to be so connected together, as to be consistent with that continuity of action so necessary to the body, and which Horace prescribes when he says, " Sit quodvis simplex duntaxat & unum." See the article EPISODE.

The unity of the epic action, Mr. Dacier observes, does not consist in the unity of the hero, or in the unity of his character and manners, though these be circumstances necessary thereto. The unity of action requires that there be but one principal action, of which all the rest are to be incidents or dependencies. See ACTION.

F. Bossu assigns three things requisite thereto ; the first, that no episode be used but what is fetched from the plan and ground of the action, and which is a natural member of that body ; the second, that the episodes and members be well connected with each other ; the third, is not to finish any episode, so as it may appear a whole action, but to let each be always seen in its quality of member of the body, and an unfinished part.

UNITY of Possession, in law, signifies a joint possession of two rights by several titles.

UNIVALVE SHELLS, in natural history, a term used to express one of the three general classes of shell-fish ; the other two being the bivalves and multivalves.

The univalve shells are those which consist only of one piece, not of two or more joined together. See

See the articles SHELL, BIVALVE, and MULTI-VALVE.

**UNIVERSAL**, something that is common to many things; or it is one thing belonging to many, or all things.

In logic, universal is either complex or incomplex. A complex universal is either an universal proposition, as every whole is greater than its part; or whatever raises a manifold conception in the mind, as the definition of a reasonable animal. An incomplex universal, is what produces only one conception in the mind, and is a simple thing respecting many; as human nature, which relates to every individual wherein it is found.

**UNIVERSALITY**, that quality which denominates a thing universal. See the preceding article.

**UNIVERSE**, a collective name, signifying the whole world, or the assemblage of heaven and earth, with all things therein.

As space is, in its own nature, every way infinite, it gives us an idea of the infinity of the universe, which can therefore be only in part comprehended by us: and that part of the universe which we can have any notion of, is that which is the subject of our senses; and of this the eye presents us with an idea of a vast extended prospect, and the appearance of various sorts of bodies disseminated through the same.

The infinite abyss of space (which the Greeks call *to mav*, the Latins *inane*, and we the universe) does undoubtedly comprehend an infinity of systems of moving bodies round one very large central one, which the Romans call *sol*, and we the sun. This collection of bodies is therefore properly called the solar system, and sometimes the mundane system, from the Latin word *mundus*, the world. See the article **SYSTEM**.

That the universe contains as many solar systems, or worlds, as there are what we call fixed stars, seems reasonable to infer from hence, that our sun, removed to the distance of a star, would appear just as a star does, and all the bodies moving about it would disappear entirely. Now, the reason why they disappear, is because they are opaque bodies, and too small to be seen at so great a distance, without an intense degree of light; whereas theirs is the weakest that can be, as being first borrowed, and then reflected to the eye. See **STAR**.

But the sun, by reason of his immense bulk and innate light, which is the strongest possible, will be visible at an immense distance; but the greater the distance, the less bright it will appear, and of a lesser magnitude: and therefore every star of every magnitude, may probably be a sun like our own, informing a system of planets, or moving bodies, each of which may be inhabited like our earth, with various kinds of animals, and stored with vegetable and other substances.

We can perceive, says Mr. Mac Laurin, no bounds of the vast expanse in which natural causes operate; nor can we fix any border or termination of the universe; and we are equally at a loss to trace things to their elements, and to discover the limits, which inclose the subdivisions of matter.

The objects, which which we commonly call great, vanish when we contemplate the vast body of the earth: the terraqueous globe itself is soon lost in the solar system; being in some parts seen as a planet, or distant star; and, in great part of the system unknown, or visible only at rare times to vigilant observers, assisted perhaps with instruments like our telescopes. The sun itself dwindles into a star: Saturn's vast orbit, and the orbits of all the comets, crowd into a point, when viewed from numberless places between the earth and the nearest fixed stars. Other suns illuminate other systems, where our sun's rays are unperceived; but all these also are swallowed up in the vast expanse of the universe. Even all the systems of the stars that sparkle in the clearest sky, must possess a small corner only of that space over which such systems are dispersed. And after we have risen so high, and left all definite measures so far behind us, we find ourselves no nearer to a term or limit; for all this is nothing to what may be displayed in the infinite expanse, beyond the remotest stars that ever have been discovered.

In this view of the universe, an august idea arises in the mind, worthy of the infinite and wise Author of nature, who can never be supposed to have created so many glorious orbs, to answer so trifling a purpose as the twinkling to mortals by night now and then; besides that, the far greatest part of the stars are never seen by us at all, as has been shewn under the article **STAR**, which see.

**UNIVERSITY**, *Universitas*, a collective term, applied to an assemblage of several colleges, established in a city, or out-town, wherein are professors in the several sciences, appointed to teach them to students; and where degrees or certificates of study in the divers faculties are taken up.

In each university four faculties are usually taught; theology, medicine, law, and the arts and sciences. See **THEOLOGY**, &c.

They are called universities, or universal schools, by reason the four faculties are supposed to take in the whole compass of study. See **FACULTY**.

In the eye of the law, an university is held a mere lay body, or community; though, in reality, it be a mixed body, composed partly of laymen, and partly of ecclesiastics.

Universities had their first rise in the XIIth and XIIIth centuries. Those of Paris and Bologna pretend to be the first that were set on foot; but then they were on a different footing from the universities among us.

Our own universities, of Oxford and Cambridge, seem entitled to the greatest antiquity of any in the world;

world; and Baliol and Merton colleges in Oxford, and St. Peter's in Cambridge, all made colleges in the XIIIth century, may be said to be the first regular endowments of this kind in Europe. For though University-college in Cambridge had been a place for students ever since the year 872, yet this, like many of the ancient colleges beyond sea, and Leyden to this day, was no proper college; but the students, without any distinction of habit, lived in citizens houses, having only meeting places to hear lectures and dispute.

In after-times, there were houses built for the students to live in society; only each to be at his own charge, as in the inns of court: these, at first, were called inns, but now halls. At last, plentiful revenues were settled on several of these halls, to maintain the students in diet, apparel, &c. and these were called colleges. See the article COLLEGE.

The universities of Oxford and Cambridge are governed next under the king, by a chancellor, who is to take care of the government of the whole university, to maintain the liberties thereof, &c. Under him is the high-steward, whose office is to assist the chancellor and other officers, when required, in the execution of their offices, and to hear and determine capital causes, according to the laws of the land, and the privileges of the university. The next officer is the vice-chancellor, who officiates for the chancellor in his absence.

There are also two proctors, who assist in the government of the university, particularly in the business of school exercise, taking up degrees, punishing violators of the statutes, &c. Add to these, a public orator, keeper of records, register, beadles, and verger.

The universities of Scotland are four, viz. those of St. Andrew, Aberdeen, Edinburgh, and Glasgow. In Ireland there is only one university, viz. that of Dublin.

UNIVOCAL, in the schools, is applied to two or more names, or terms, that have but one signification, in opposition to equivocal, which is where one term has two or more significations. See the article EQUIVOCAL.

Our univocal terms are such, whose name as well as nature, is the same, in opposition to equivocals, whose names are the same, but their natures very different.

The ancients believed that all perfect animals were produced by univocal generation; that is, by the sole union or copulation of a male and female of the same species or denomination; and that insects were produced by equivocal generation, without any seed, and merely of the corruption of the earth, exhaled, and, as it were, impregnated, by the sun's rays: but this doctrine of insects is now exploded.

UNLAWFUL, illegal, something prohibited by, or contrary to, the terms of law, either divine or human. See LAW.

UNLAWFUL ASSEMBLY, the meeting of three or more persons together, by force to commit some unlawful act, as to assault any person, to enter his house or land, &c. and thus abiding together, whether they attempt the execution or not.

UNLIMITED, or INTERMEDIATE PROBLEM, is such a one as is capable of infinite solutions. See PROBLEM.

UNMOOR, a term used at sea: when a vessel which was riding at anchor weighs the same, or gets it up, in order to sail, they say she is unmooring.

VOCABULARY, *Vocabularium*, in grammar, denotes the collection of the words of a language, with their significations, otherwise called a dictionary, lexicon, or nomenclature.

A vocabulary is properly a lesser kind of dictionary which does not enter so minutely into the origins and different acceptations of words.

VOCAL, something that relates to the voice or speech: thus vocal music is that set to words, especially verses, and to be performed by the voice, in contradistinction to instrumental music, composed only for instruments, without singing. See the article VOICE.

VOCATIVE, in grammar, the fifth state or case of nouns.

When we name the person we are speaking to, or address ourselves to the thing we are speaking of, as if it were a person, the noun, or name, requires a new relation, which the Latins and Greeks express by a new termination, called the vocative; as from *dominus*, a lord, is formed the vocative *domine*, O lord.

In English, and most of the modern languages, the vocative is expressed in nouns that have an article in the nominative, by omitting that article; as *the Lord is my hope*: *Lord, thou art my hope*: though on many occasions, we use an interjection.

VOICE, *Vox*, a sound produced in the throat and mouth of an animal, by an apparatus of instruments for that purpose. See the article SOUND.

Voices are either articulate or inarticulate. Articulate voices are those whereof several conspire together to form some assemblage or little system of sounds; such are the voices expressing the letters of an alphabet, numbers of which joined together, form words. Inarticulate voices are such as are not organized, or assembled into words; such is the barking of dogs, the braying of asses, the hissing of serpents, the singing of birds, &c.

The formation of the human voice, with all the varieties thereof observed in speech, music, &c. makes a very curious article of inquiry; and the apparatus and organism of the parts administering thereto, is something exceedingly surprising.

Those parts are the trachea or wind-pipe, through which the air passes and repasses into the lungs; the larynx

larynx, which is a short cylindric canal at the head of the trachea; and the glottis, which is a little oval cleft or chink left between two semicircular membranes stretched horizontally within the larynx; which membranes, though capable of joining close together, do generally leave an interval, either greater or less, between them called the glottis.

The long canal of the trachea, terminated at top with the glottis, appears so like a flute, that the ancients made no doubt but the trachea contributed the same to the voice, as the body of the flute does to the sound of that instrument. Galen himself fell in some measure into the mistake; he perceived indeed, that the principal organ of the voice was the glottis, but he still allowed the trachea a considerable share in the production of the sound.

Galen's opinion was followed by all the ancients after him, and even by all the moderns before M. Dodart: but that author observes, that we do not either speak or sing when we inspire or take in the air, but only when we expire or expel it; and that the air coming out of the lungs, passes always out of the minuter vesicles of that part into larger, and at last into the trachea itself, which is the largest of all: that thus its passage becoming still more free and easy, and thus more than ever in the trachea, it can never undergo such a violence, and acquire such a velocity in that canal, as is required to the production of sound: but that as the aperture of the glottis is very small, in comparison with the width of the trachea, the air can never get out of the trachea by the glottis, without a vast compression and augmentation of its velocity; and that by this means in passing, it communicates a brisk agitation to the minuter parts of the two lips of the glottis, and gives them a kind of spring, and occasions them to make vibrations, which communicated to the passing air, are what really occasion the sound. The sound thus formed, proceeds into the cavity of the mouth and nostrils, where it is reflected and resounds: and on this resonance, M. Dodart shews, it is that the agreeableness of the voice intirely depends. The different consistences, forms, &c. of the divers parts of the mouth, contribute to the resonance, each in their way; and from this mixture of so many different resonances in their due proportion, there results an harmony in the human voice inimitable by any musician.

Hence it is that when any of these parts are disordered, e. g. when the nose is stopped, the voice becomes displeasing. This resonance in the cavity of the mouth, does not seem to consist in a simple reflexion, such as that of a vault, &c. but in a resonance proportionate to the tones of the sound sent into the mouth from the glottis; and accordingly we find this cavity to lengthen and shorten itself, according to the depth or acuteness of the tone.

As the organs that form the voice make a kind of wind instrument, one might imagine to find some provision therein answerable to that which produces the difference of tone in some other wind-instruments. The tone, therefore, must be attributed, either to the mouth and nostrils, which occasion the resonance, or to the glottis, which produces the sound: and as all the different tones are produced in man by the same instrument, it follows, that the part which produces them, must be capable of changes answerable thereto. The different apertures of the lips of the glottis, it is proved, produce all the different tones in the several parts of music, and the manner is thus. The voice, it is shewn, can only be formed by the glottis, but the tones of the voice are modifications of the voice, and these can only be produced by the modifications of the glottis. Now the glottis is capable only of one modification, which is the mutual approach or recess of its lips; it is this, therefore, produces the different tones. Now that modification includes two circumstances; the first and principal is, that the lips are stretched more and more from the lowest tone to the highest: the second is, that the more they are stretched, the nearer they approach. From the first, it follows, that their vibrations will be so much the quicker, as they come nearest their highest tone; and that the voice will be just, when the two lips are equally stretched; and false, when unequally; which agrees perfectly well with the nature of string instruments. From the second, it follows, that the higher the tones are, the nearer will they approach to each other, which agrees perfectly well with instruments governed by reeds or plugs.

The degrees of tension of the lips, are the first and principal cause of tones, but their differences are insensible; the degrees of approach are only consequences of that tension, but their differences are more easily assigned. They are different apertures that produce, or at least that accompany, different tones, both in natural wind instruments, and artificial ones; and the diminution of the aperture, raises the tones both of the glottis, and the reed.

VOICE, in grammar, a circumstance in verbs, whereby they come to be considered as either active or passive, i. e. either expressing an action impressed on another subject, as, *I beat*, or receiving it from another, as, *I am beaten*.

The Greeks have a third voice called the medial voice, thus denominated, because it has sometimes an active and sometimes a passive signification; tho' generally it is of an active signification. With regard to the termination of this medial voice, it is to be observed, that the present and imperfect tenses are the same with those of the passive voice; or, in other words, when these tenses of the passive voice are taken actively, they are then denominated of the medial voice.

**VOID SPACE**, in physics. See the article **VACUUM**, &c.

**VOID** and **VOIDABLE**, are terms frequently used in our law; as a thing that is done contrary to law at the time of the doing, it is said to be void, and no person shall be bound thereby. But where a thing is only voidable, and not void, though it be what the person that did it ought not to have done, yet when it is done, the doer cannot avoid the same, notwithstanding by some act in law it may be void in his heir, &c. It has been held, that the bond of an infant, or one non compos mentis, is void, because the law has not appointed the doing any thing to avoid such bonds. A lease for term of life, which is voidable, must be made void by re-entry, &c. and a deed is generally avoided by special pleading.

**VOIDED**, in heraldry, is understood of an ordinary whose inner or middle part is out, leaving nothing but its edges to shew its form, so that the field appears through it. Hence it is needless to express the colour or metal of the voided part, because it must of course be that of the field. The cross voided, differs from the cross fimbriated, in that the latter does not shew the field through it, as the other does; and the same obtains in other ordinaries.

**VOIDER**, in heraldry, one of the ordinaries whose figure is much like that of a flask of flanch, only that it doth not bend so much.

**VOL**, among heralds, signifies the two wings of a fowl joined together, borne in armoury, as being the whole that makes the flight. Accordingly, a demivol is a single wing.

**VOLA**, the palm or inside of the hand, comprehended between the fingers and the wrist.

**VOLANT**, in heraldry, is when a bird in a coat of arms is drawn flying, or having its wings spread out.

**VOLATILE**, in physics, is commonly used to denote a mixed body whose integral parts are easily dissipated by fire or heat; but it is more properly used for bodies whose elements or first component parts are easily separated from each other, and dispersed in air. For as any mixed body is said to be fixed in a double sense, so may it be said to be volatile two ways; whence the same body, *e. gr.* mercury, is both volatile and fixed at the same time; since, as its integral parts, or those which still retain the nature of mercury, are easily separable by fire, and readily flies away, it is said to be volatile; and yet as it is very difficult to destroy its contexture, and resolve it by fire, or any other menstruum, into its first elements, it is said to be fixed; the same may be said of sulphur, antimony, &c. See the article **FIXED BODIES**.

Minerals, for the generality, are less volatile than vegetables, and vegetables are less so than animals. The chemists distinguish greatly between volatile salts and fixed salts. The capitals of aludels stop and

collect the volatile parts of substances in sublimation, and make what we call flowers.

The particles of fluids which do not cohere very strongly together, says Sir Isaac Newton, and are of such a smallness as renders them most susceptible of those agitations which keep liquors in a fluor, are most easily separated and rarefied into vapour; and, in the language of the chemists, they are volatile, rarifying with an easy heat, and condensing with cold. But those which are grosser, and by that means less susceptible of agitation, or cohere by a stronger attraction, are not separated without a stronger heat, or perhaps not without fermentation; these are what the chemists call fixed bodies.

When the fire decomposes any mixed body, the parts most disposed to receive a great motion are soonest loosened, and rise up in the order which the differences of that disposition give them, the rest remaining immoveable at the bottom of the vessel. Those that rise first are called volatile parts; such are phlegm, oil, spirits and salts, both urinous and alkalious. The parts remaining, viz. earth and lixivial salts, are called fixed.

**VOLATILISATION**, or **VOLATILIZATION**, the act of rendering fixed bodies volatile, or of resolving them by fire into a fine subtile vapour or spirit, which easily dissipates and flies away. All bodies, even the most fixed, as gold, may be volatilized; either of themselves, or with the admixture of some volatile substance, or spirit, by distillation or sublimation. See the articles **GOLD**, **DISTILLATION**, &c.

**VOLATILITY**. See the articles **VOLATILE** and **SUBLIMATION**.

**VOLCANO**, or **VULCANO**. See the article **VULCANO**.

**VOLERY**, a great bird-cage, so large that the birds have room to fly up and down in it.

**VOLITION**, the act of willing. See the article **WILLING**.

**VOLKAMERIA**, in botany, a genus of plants, whose flower is monopetalous and ringent; the tube is cylindric, and double the length of the cup; and the limb is divided into five almost equal segments: the stamina are four long slender filaments, topped with single antheræ: the fruit is a roundish bilocular capsule, containing two furrowed nuts.

Volkameria grows naturally in India; the root sends forth many weak shrubby stalks, which rise to the height of twelve or fourteen feet; they are covered with a white bark, and furnished with oval spear-shaped leaves, about three inches long and one and a half broad, of a lucid green colour, and smooth; they are placed by pairs on short footstalks: the flowers are produced from the wings of the stalks, in umbellated bunches, like those of the jasmine, to which the flowers have a great resemblance; their colour is white, and they have an agreeable odour.

This plant is increased, with us, from cuttings in the summer months; but being tender, requires a hot-house for its preservation in winter.

**VOLKAMERIA**, is also a name given by some authors to the *tinus* of Linnæus. See the article **TINUS**.

**VOLLEY**, a military salute, made by discharging a great number of fire-arms at the same time.

**VOLT**, or **VOLTE**, in the manege, a round or circular tread; and hence, by the phrase, to make volts, is understood a gate of two treads, made by a horse going sideways round a center, in such a manner, that these two treads make parallel tracts, one larger, made by the fore-feet, and another smaller, made by the hind-feet, the croup approaching towards the center, and the shoulders bearing outwards.

Sometimes the volt is of one tread; as when a horse makes volts in corvets, and in caprioles, so that the haunches follow the shoulders, and move forwards on the same tread.

In general, the way and tract of a volt is made sometimes round, sometimes oval, and sometimes square, of four straight lines; so that these treads, whether round or square, inclose a terrain, or manege ground, the middle of which is sometimes distinguished by a pillar, or else by an imaginary center, which is there supposed in order to regulate the distances and the justness of the volt.

A demi-volt is a demi-round of one or two treads, made by the horse at one of the corners of the volt, or else at the end of the line of the passade; so that being near the end of this line, or one of the corners of the volt, he changes hands, to return by a semi-circle.

A renverfed volt is a tract of two treads, made by the horse, with his head to the center, and his croup out; so that he goes sideways upon a walk, trot, or gallop, and traces out a small circumference with his shoulders, and a larger one with his croup.

This different situation of the shoulders and the croup, with respect to the center, gave this volt the name of renverfed, as being opposite in situation to the former.

**VOLUBILIS**, in botany, a name used by Dillenius for a species of convolvulus. See the article **CONVOLVULUS**.

**VOLUME**, *Volumen*, in matters of literature, a book, or writing, of a just bulk to be bound by itself. The name is derived from the Latin *volvere*, to roll up; the ancient manner of making up books being in rolls of bark or parchment.

Foreign philosophers use the phrase, volume of a body, for its bulk, or the space contained within its superficies.

**VOLUNT**, *Voluntas*, in law, is when a tenant holds lands, &c. at the will of the lessor, or lord of the manor. See the article **TENURE**.

**VOLUNTARY**, in music, a piece played by a musician, extempore, according to his fancy. This is often used before he begins to set himself to play any particular composition, to try the instrument, and to lead him into the key of the piece he intends to perform.

**VOLUNTEERS**, in the military art, persons who, of their own accord, and at their own expence, serve in the army.

**VOLUTA**, in natural history, a genus of univalve shells, with an oblong mouth, a clavicle sometimes erect and sometimes depressed, and sometimes coronated at top.

To this genus belong the admiral-shells, tiger-shells, &c.

**VOLUTE**, *Voluta*, in architecture, a kind of spiral scroll, used in the Ionic and Composite capitals: whereof it makes the principal characteristic and ornament.

There are several diversities practised in the volute. In some, the list or edge, throughout all the circumvolutions, is in the same line or plane; such are the antique Ionic volutes, and those of Vignola. In others, the spires or circumvolutions fall back; in others, project and stand out. Again, in others, the circumvolutions are oval; in others, the canal of one circumvolution is detached from the list of another by a vacuity or aperture. In others, the rind is parallel to the abacus, and springs out from behind the flower thereof. In others, it seems to spring out of the vase from behind the ovum, and rises to the abacus, as in most of the fine Composite capitals.

**VOLVULUS**, in medicine, a name which some authors give to the iliac passion, by others called chordapfus, and by others miserere mei. See the article **ILIAC**.

**VOMER**, in anatomy, a bone of the upper jaw, situated between the bones of the palate and the sphenoidal bone, being also joined to the process of the ethmoides, and part of the lower jaw, and having its fore part, which is spongy, continued to the middle cartilage of the nose, and making, in conjunction with it, the septum nasi. See the articles **NOSE** and **MAXILLA**.

**VOMICA**, in medicine, is commonly taken for a suppurated imposthume, or an abscess with a supuration.

*Nux VOMICA*, in pharmacy, a flat, compressed, round fruit, of the breadth of a shilling, or somewhat more, and of about the thickness of a crown piece.

Its surface is not much wrinkled or corrugated, but sometimes marked with tolerably regular fibres, running from the center to the circumference; it is somewhat downy or woolly, and of an extreme firm texture, tough like horn, and of a pale greyish-brown colour.

It has a sort of umbilicus on each side of the center, and is more prominent on one side, and more depressed on the other; it is very difficultly cut or broken, and leaves a smooth and glossy surface behind the knife; it is moderately heavy, and is of a somewhat paler colour within than on the surface; it has no smell, but an extremely bitter taste.

We have it only from the East-Indies, whence it is brought with another drug called the *lignum colubrinum*. It was held by many to be the root of a plant, and by others to be a fungus or an excrement. But it is in reality the nucleus of a fruit of an East-Indian tree, the wood of which is the *lignum colubrinum* of the shops. See the article *COLUBRINUM*.

Some have prescribed small doses of the *nux vomica*, as a specific against a gonorrhœa, and others against quartan agues. But we have so many safe and good medicines for all these purposes, that there seems no occasion for our having recourse to such as these, which shew so many signs of mischief.

There is another species of the *nux vomica*, described by Breyhius under the name of *modira caniram*, and *nux vomica officinarum vera*. Commelin determines this tree, not the former, to afford the true *nux vomica*, and the true *lignum colubrinum* of the shops; and Herman, on the other hand, is as positive as to the other.

There is also another sort of *nux vomica*, which is much smaller than the former, very like them, and has all their qualities: it is the fruit of another species of the same genus, which is the tree that furnishes the true officinal wood.

**VOMIT, or EMETIC**, in pharmacy. See the article *EMETIC*.

**VOMITING**, in medicine, a retrograde spasmodic motion of the muscular fibres of the œsophagus, stomach, and intestines, attended with strong convulsions of the muscles of the abdomen and diaphragm, which when gentle, create a nausea; when violent, a vomiting. These convulsive disorders proceed from the immoderate quantity, or acrimony of the food; from poisons; from some injury of the brain, as a wound, contusion, compression, or inflammation of that part; from an inflammation of the diaphragm, stomach, intestines, spleen, liver, kidneys, pancreas, or mesentery; from an irritation of the gula; from a disorderly motion of the spirits, by unaccustomed agitation in a coach, ship, or otherwise, or from the idea of something nauseous.

The two principal curative indications to be observed are, first, to quiet and compose the convulsive and unruly motion of the stomach; and, secondly, to oppose and subdue the material causes of the disorder.

The first intention is answered by corroborating and antispasmodic medicines, such as saffron and

castor, with the tasteless powders, as coral, crab-claws, and oyster-shells; powders composed of cinnamon, the leaves of mint, nutmeg, orange-peel, *calamus aromaticus*, and other such simples, are also of great service. And if anodynes are found necessary, the *stora* pill, or Sydenham's laudanum, are to be given.

While these medicines are taken internally, there may also be applied outwardly, to the region of the stomach, such things as have power to repress its disorderly motions; of this kind are the oil of mint, nutmeg, and the like, with balsam of Peru; these oils may be reduced to a proper consistence, with this balsam, for the spreading on leather, and laying on for some time. Hungary-water, and other like spirits, are of great use also, rubbed on with the hand; and to these may be added yeast, and the strongest wine-vinegar applied hot to the part.

Finally, an excellent application is balsam of Peru alone, reduced to the consistence of a cataplasm, with crumb of bread.

The methods to be used to remove the material causes of the vomiting, are next to be considered: if it be of the petuitous kind, and owing to crudities in the primæ viæ, and a viscid mucus sticking to them, it is best cured by an emetic: if the vomiting of itself be found not sufficient to carry off the fœces which occasion it, and the patient continues, after the fits of vomiting, afflicted with a nausea and heart-burn; in this case, a large quantity of warm water, with a little butter, may serve the purpose; or if this be found insufficient, a dose of *ipécacuanha* is to be given.

**VOMITINGS in Infants**. See *INFANT*.

**VOMITING of Blood, Vomitus Cruentus**, a very dangerous kind of hæmorrhage, consisting in a bringing up by vomit of pure and unmixed blood from the stomach, and being a method, used by nature to throw off a portion of the blood, which molests the whole in the vena porta, and by that means to facilitate the circulation of the rest of the mass. See *HÆMORRHAGE*.

This distemper sometimes arises from internal causes, and is regularly periodical, observing the stated times of the eruptions of the menses, or other natural discharges; sometimes it arises from accidents, such as the giving of violent purging or emetic medicines, or corrosive ones. Among the preceding signs of this disorder, are to be reckoned a sensation of straitness and anxiety in the præcordia, with tension, and involuntary sighs; with a nausea or sickness of the stomach, and a straining to vomit; which is more violent than in vomiting on any other occasion; after this the blood is thrown up pure, and the vomiting then ceases, till, after a plain sensation of more blood being collected in the stomach, the efforts to discharge it in the same manner are again renewed. The quicker the blood is thrown up,

up, after its being discharged into the stomach, the more fluid and more florid it appears; the longer it is detained there, the blacker and thicker it appears.

A vomiting of blood is but an uncommon disorder. It more frequently attacks women than men; among the female sex it is principally seen in those whom the menses have left too early in life, or who have had violent suppressions of them for a long time. In men, this distemper seldom seizes any but those who have been used to periodical discharges from the hæmorrhoidal vessels, and who have had them suddenly stopped; and they are then usually first attacked with violent pains in the left hypochondrium. People of scorbutic habits, and such as have had quartan agues of long standing, have been sometimes thus affected. And, beside these natural causes, people of all ages and sexes may vomit blood, from external injuries.

A vomiting of blood is ever a dangerous disorder; for though the quantity of blood thrown up is seldom so great as to occasion immediate death, yet it generally degenerates into a tabes in men, and into a cachectic habit in women. It is less dangerous to young women, than to any other persons; and when it is periodical, especially when it observes the times of the menstrual discharges, is much less dangerous than under any other circumstances. During the paroxysm, the proper medicines are powder of nitre, cinnabar, and the absorbent substances, such as crab's-eyes, or the like, and afterwards bleeding, cupping, and gentle purges; and diaphoretics are to be given for some time.

**VORTEX**, in meteorology, a whirlwind, or sudden, rapid, or violent motion of the air in gyres or circles.

Vortex is also used for an eddy or whirlpool; or a body of water, in certain seas or rivers, which runs rapidly around, forming a sort of cavity in the middle.

**VORTEX**, in the Cartesian philosophy, is a system or collection of particles of matter moving the same way, and round the same axis.

Such vortices are the grand machines, whereby those philosophers solve most of the motions and other phenomena of the heavenly bodies. Accordingly, the doctrine of these vortices makes a great part of the Cartesian philosophy.

But this doctrine of vortices is at best merely hypothetical. It does not pretend to shew by what laws and means the celestial motions are really affected, so much as by what means they possibly might, in case it should have so pleased the Creator. But we have another principal which accounts for the same phenomena, as well, nay, better, than that of vortices; and which we plainly find has an actual existence in the nature of things; and this is gravity, or the weight of bodies.

The vortices then should be cast out of philosophy, were it only that two different adequate causes of the same phenomena are inconsistent.

But we have other objections against it. For, 1. If the bodies of the planets and comets be carried round the sun in vortices, the bodies of the parts of the vortex immediately investing them, must move with the same velocity, and in the same direction; and besides, must have the same density, or the same vis inertia. But it is evident that the planets and comets move in the very same parts of the heavens, with different velocity and in different directions. It follows, therefore, that these parts of the vortex must revolve at the same time in different directions, and with different velocities; since one velocity and direction will be required for the passage of the planets, and another for that of comets. 2. If it were granted that several vortices were contained in the same space, do penetrate each other, and revolve with divers motions; since those motions must be conformable to those of the bodies which are perfectly regular, and performed in conic sections; it may be asked, how they should have been preserved entire to so many ages, and not disturbed nor confounded by the adverse actions and shocks of so much matter as they meet withal? 3. The number of comets is very great, and their motions perfectly regular, observing the same laws with the planets, and moving in conical orbits, which are exceedingly excentric. Accordingly they move every way, and to all parts of the heavens, freely pervading the planetary regions, and going frequently contrary to the order of the signs; which would be impossible, unless these vortices were away.

4. If the planets move round the sun in vortices, those parts of vortices next the planets, we have already observed, would be equally dense with the planets themselves, consequently, the vortical matter, contiguous to the perimeter of the earth's orbit, would be as dense as the earth itself: and that between the orbits of the earth and saturn, it must be as dense or denser. For a vortex cannot maintain itself, unless the more dense parts be in the center, and the less dense towards the circumference; and, since the periodical times of the planets are in a sesquialterate ratio of their distances from the sun, the parts of the vortex must be in the same ratio. Whence it follows, that the centrifugal force of the parts will be reciprocally as the squares of the distances. Such, therefore, as are at a greater distance from the center, will endeavour to recede therefrom with the less force. Accordingly, if they be less dense, they must give way to the greater force, whereby the parts nearer the center endeavour to rise. Thus the more dense will rise, and the less dense descend; and thus there will be a change of places, till the whole fluid matter of the vortex be so adjusted, as it may rest in æquilibrium.

Thus

Thus will the greatest part of the vortex, without the earth's orbit, have a degree of density and inactivity, not less than that of the earth itself. Whence the comets must meet with a very great resistance, contrary to all appearances.

**VOTE**, the suffrage or resolve of each of the members of an assembly, where any affair is to be carried by a majority; but more particularly used for the resolves of the members of either house of parliament.

**VOTIVE MEDALS**, those on which are expressed the vows of the people for the emperors or empresses.

**VOUCHER**, in law, is a person called into court, to make good another's warranty, who is either to defend the right against the demandant, or yield him other lands to the value, &c.

**VOUCHER** also signifies a receipt or acquittance in cases of account.

**VOW**, a solemn and religious promise, or oath.

The use of vows is found in most religions. They make up a considerable part of the pagan worship, being made either in consequence of some deliverance, under some pressing necessity, or for the success of some enterprize. Among the Jews, all vows were to be voluntary, and made by persons wholly in their own power; and if such person made a vow, in any thing lawful and possible, he was obliged to fulfil it. If he appointed no particular time for accomplishing his vow, he was bound to do it instantly, lest by delay he should prove less able, or be unwilling, to execute his promise. Among the Romanists, a person is constituted a religious by taking three vows, that of poverty, chastity, and obedience.

**VOWS**, *vota*, among the Romans, signified sacrifices, offerings, presents, and prayers, made for the Cæsars and emperors, particularly for their prosperity and continuance of their empire. These were at first made every five years, than every fifteen, and afterwards every twenty, and were called *quinquennialia*, *decennialia*, and *vincennialia*.

**VOWEL**, *vocalis*, in grammar, a letter which affords a complete sound of itself, or a letter so simple as only to need a bare opening of the mouth to make it heard, and to form a distinct voice.

The vowels are six in number, viz. A, E, I, O, U, Y, and are called vowels in contradistinction to certain other letters, which, depending on a particular application of some part of the mouth, as the teeth, lips, or palate, can make no perfect sound without an opening of the mouth, that is, without the addition of a vowel, and are therefore called consonants. See the article **CONSONANT**.

Grammarians reckon also eight semi-vowels, viz. F, H, L, M, N, R, S, Z, so denominated because they approach nearer a vowel in the pronunciation. Of these semi-vowels four, viz. L, M, N, R, are called liquid.

**UPLAND**, denotes high ground, or, as some

call it, *terra firma*, by which it stands opposed to such as is moorish, marshy, or low.

The uplands lie either on the tops of hills, or on their sides, or on the slopes of rising grounds. They sometimes have a sandy soil, sometimes a rocky, gravelly, or loamy one; and sometimes they consist of a tough clay, or a black mould; they are used by the farmers, either for grazing or corn, as they happen to be more moist or more dry; and this difference depends upon their situation and nature. Those lands which lie flat upon the tops of hills, are usually the driest, and those which form the slopes or sides, are generally the moistest, because of the wet that oozes through them. The upland meadows have some disadvantage, as they often need mending or feeding, which those that lie lower do not; but then they make amends for this in their hay, which is always much finer and sweeter than that of the low lands.

**UPRIGHT**, in architecture, a representation or draught of the front of a building, called also an elevation or orthography.

**UPRIGHT**, in heraldry, is used in respect of shell fishes, as crevices, &c. when standing erect in a coat. Inasmuch as they want fins, they cannot, according to Guillim, be properly said to be hauriant, that being a term appropriated to scaly fishes.

**URACHUS**, in anatomy, a membranous canal in the fœtus of quadrupeds in general, of a pyramidal figure, extended immediately from the fundus of the bladder to the navel, and after passing this, it is by degrees enlarged, and makes its way into the allantois at right-angles each way, or nearly so, and conveys the urine from the bladder into the cavity of this membrane. In the human fœtus, the whole urachus is not previous, or very rarely so; it is usually found solid, in form of a ligament. It scarce appears probable, therefore, that it serves the office of discharging the urine from the bladder in this as in the former case, and especially as there is no such membrane as the allantois in the human body, nor any cavity formed for the reception of so great a quantity of fluid.

**URDE**, or **URDE'E**, in heraldry. A cross ur-de seems to be the same with what we otherwise call chleche, or chleché.

**URED**, the blasting or blighting of trees or herbs. It is sometimes used by physicians for an itching or burning of the skin. See the article **BLIGHT**.

**URENA**, Indian-mallow, in botany, a genus of plants, whose flower consists of five oblong petals, broad at their apex, but narrow and joining at their base; the filaments are numerous, coalescing in a cylinder at their base, and topped with roundish antheræ: the fruit is a round echinated pentagonal capsule, having five cells, each containing an angular seed.

**URETERS**, *ouventres*, in anatomy, two membranaceous

branaceous tubes or pipes, nearly cylindric in figure, and of about the thickness of a quill; but their diameter is very uncertain.

They arise from the kidneys, one from each, and terminate in the urinary bladder. At their origin in the kidneys they are expanded into the form of a funnel, and this expansion makes the pelvis of the kidneys. See the article PELVIS.

At their termination, which is in the hinder and lower part of the bladder, they pass obliquely in between its membranes, and open into the bladder by very narrow orifices, and can admit nothing into them from the bladder. They are not straight, but somewhat bent, so as to resemble the letter S; their substance is membranaceous, and they are composed of three coats: the first, a common one, from the peritonæum; the second, a thin muscular one; and the third, a nervous one, covered with a lubricous humour; and in this there are sometimes discovered glands. The blood-vessels and nerves come from the adjacent parts.

The use of the ureters is to receive the urine secreted in the kidneys from the pelvis, and to carry it to the urinary bladder. When these are obstructed, a suppression of urine is the consequence; for there is no other way for the urine to get into the bladder but through them. They are often found of an unnatural size, owing to stones concentered from among the urine.

URETHRA, *ουρητρα*, in anatomy, a membranaceous tube or canal, of a cylindric figure, arising from the neck of the bladder, and continued to the pudendum, serving to discharge and carry off the urine and semen.

The length of the urethra is very different in both sexes. In man it is twelve or thirteen inches, from the neck of the bladder to the extremity of the glans. It is situated in a kind of narrow furrow, formed between the corpora cavernosa, in the bottom or lower part of the penis. It does not run perfectly straight, but is bent in a very singular manner. Its cavity is as large as that of a goose-quill.

It is composed of two robust membranes, an exterior and interior; their substance is thin and tough, and between them there is a spongy or cavernous matter, in which some authors pretend to have discovered glands, but this is uncertain.

The bulb of the urethra is that part of it next to the prostate; it is much thicker than the rest of the tube, and is about an inch long, and in some measure resembles a walnut. It is of a thick and spongy texture.

The interior surface of the urethra, is full of roundish and oblong foraminulæ and furrows, out of which there may often be pressed a thick viscous fluid, the use of which is to lubricate the urethra, and to defend it from the acrimony of the urine. See PENIS, &c.

The urethra or urinary passage in women, usually called *meatus urinarius*, is situated straight under the clitoris, and shews itself by a little eminence. Its length is about two fingers breadth; its diameter is greater than that in man, but somewhat narrower at the end than elsewhere. It is capable of great dilatation. There are in it certain little ducts, which convey to its inner surface a mucous humour, for lubricating and defending it from the acrimony of the urine, like those in man; but their origin is uncertain.

URIM and THUMMIM, among the ancient Hebrews, a certain oracular manner of consulting God, which was done by the high-priest dressed in his robes, and having on his pectoral, or breast-plate.

Various have been the sentiments of commentators concerning the urim and thummim. Josephus and several others, maintain, that it meant the precious stones set in the high-priest's breast-plate, which, by some extraordinary lustre, made known the will of God to those who consulted him.

Spencer believes, that the urim and thummim were two little golden figures shut up in the pectoral, as in a purse, which gave responses with an articulate voice. In short, there are as many opinions concerning the urim and thummim, as there are particular authors that wrote about them.

The safest opinion, according to Broughton, seems to be, that the words urim and thummim signify some divine virtue and power, annexed to the breast-plate of the high-priest, by which an oracular answer was obtained from God when he was consulted by the high-priest; and that this was called urim and thummim, to express the clearness and perfection which these oracular answers always carried with them; for urim signifies light, and thummim, perfection; these answers not being imperfect and ambiguous, like the heathen oracles, but clear and evident.

The use made of the urim and thummim was to consult God, in difficult cases, relating to the whole state of Israel; and sometimes in cases relating to the king, the sanhedrim, the general of the army, or some other great personage.

URINAL, in medicine, a vessel fit to receive and hold urine, and used accordingly for the convenience of sick persons.

It is usually of glass, and crooked; and sometimes it is filled with milk to assuage the pain of the gravel. See the articles UROCRITERIUM, STONE, and URINE.

URINAL, in chemistry, is an oblong glass vessel, closed for making solutions, and so called from its resemblance to the glasses in which urine is set to settle for the inspection of the physician. See the preceding article.

URINARIA FISTULA, the urinary passage, or urethra. See URETHRA.

**URINE**, *Urina*, a serous and saline fluid, of a citron-colour, separated from the blood, and carried by the emulgent arteries to the kidneys, whence it descends to the bladder by the ureters, and is, from time to time, emitted thence by the canal of the urethra.

The urine is therefore the serosity of the blood, but not pure, for it is loaded with saline, sulphureous, and terrestrial particles, of which it is the menstruum and the vehicle. The sides of the bladder are guarded by a mucilaginous fluid, excreted by the glands which are between its coats, by which means the urinous salts make the less impression upon it. This fluid forms the glair which falls to the bottom of the vessel when a person is afflicted with the stone.

It is observable, that there are three sorts of substances differently placed in the urine, viz. the nubecula, the encœrema, and the hypostasis.

The nubecula is a sort of a pellicle which swims on the top of the urine, and consists of the saline and fibrous particles of the blood, mixed with the serosity: when it is exposed to the fire, it changes to a crustaceous substance. The encœrema, or suspension, is a white light spongy matter, which swims in the middle of the urine, consisting of particles of a different nature. The hypostasis, or sediment, is a saline, sulphureous, and terrestrial matter, which precipitates to the bottom of the urine.

The urine of four-footed beasts is troubled and muddy, that of men is more clear and limpid. In infants it is more pale and thick than that of middle-aged persons. In the very old it is more clear, thin, and has not so much colour. In hot, bilious constitutions, it is more of a saffron colour: in the cold and pituitous, pale. Wine drinkers have it of a higher colour, and more thick: in those that use much exercise it is little and red: in the idle it is pale with a large sediment. After meals it is copious, insipid, light, raw, and without smell: and after long fasting, it is of a high colour, acrid, and little. Those that sweat much make little water, which is more muddy and yellow. Diseases cause a remarkable change in the urine. Light, thin, watry urine, shews the person to be afflicted with internal spasms, the hysteric passion, the hypochondriac pains, the cardialgia, the stone or gravel, or convulsive colic. In diseases of the head, such as the vertigo, phrensy, madness, melancholy, and epilepsy, the urine is always thin and light. It is likewise the same in the more grievous afflictions of the nerves from poison or worms. This state of the urine not only happens in the fits, but some days before and after.

When the urine is thin, aqueous, and always white, it presages danger in obstinate diseases: if it is copious in the state of fevers, and before the cri-

sis, it portends a phrensy. In internal inflammations it is always dangerous, the more copious the worse. After a dysentery, a spotted fever, or the small-pox, this kind of urine is common. In a cachexy, leucophlegmatia, enormous bleedings in the beginning of an anasarca, in the green-sickness, in a suppression of the menses, the urine is crude, turbid, pale, greenish, or of a light citron colour, and copious. In all preternatural febrile heats, the urine is yellow or red, and in small quantities: such kind of urine as is more or less red, or thin and light, or thick and heavy, is usually in intermitting and continual fevers. In the fit, that is, in its exacerbation or state, the urine is thin, clear, and without sediment. In an ardent and bilious fever, the urine is generally pellucid, but of a flame-colour. In intermittents after the fit, and on the well day, it is thick, and deposits a sediment. If this happens in continual fevers after the crisis, it shews the fever to be ended. If the sediment is of a rosy or purple colour, it shews the blood is in fault, as is evident in continual fevers. When it is intensely yellow, it shews that the bile is in fault. When it is brown or black, there is plenty of black bile, as in a scorbutic or miliary fever, and in quartans of a dangerous nature. When it is very plentiful, and full of viscid and crude humours, in replete, obese, and spongy bodies, it shews the obstinacy of an intermitting fever.

As it is a good sign when the urine is thick and deposits a sediment, in fevers; so, on the contrary, if there is no sediment in intermitting fevers, but the urine continues clear, and lets fall no sediment in the cold fit, it is a very bad sign. If, after the fit, it has no sediment, but is pellucid, it is a very bad omen. In all inflammatory fevers, if the urine is clear and of a purple colour, or brown, and of a deep colour, frothy and without sediment, it is a bad sign. Likewise, it is always observed, that in a continual fever, if the urine is turbid, and does not grow clear either by the fire or rest, nor deposits a sediment, it is a very dangerous presage; it is likewise very bad, when in continual fevers, it is thick on the first days, and in the remainder, especially the critical days, it is thin and without sediment. In the decline of catarrhal fevers, and in the small pox and measles, if the urine was clear and aqueous, but is now thick and high coloured, with a sediment, it is a certain sign that the disease remits.

In consumptions, and all other violent and chronic diseases, if the urine is thick, high-coloured, and a dark red, with a copious sediment, and a fatness swims upon the urine, and adheres to the sides of the urinal, the body at the same time wasting away, it is a sign of a slow hectic fever, which is generally fatal. The like danger is threatened when in dropical persons the urine is like that of hectics,

hætic, for its scarcity is a sign that the lymph is extravasated into some cavity or porous substance; and if the colour is of a deep red, with a gross sediment, it shews the intestine motion and heat dissolves the blood, that the liver is obstructed; whence a bilious fordes is separated therefrom.

In chronical diseases, without a fever, when the urine is thick, high-coloured, and of a reddish-brown, as well as heavy, as in the confirmed scurvy, gout, scorbutic palsy, and in extreme old age, as also in a nephritic passion, when the pains cease, as well as in the yellow and black jaundice, it shews a plenty of saline and sulphureous excrementitious parts, wherewith the blood and humours abound, and are not duly secreted therefrom, by reason of an obstruction of the liver. Willis has observed, that patients dying of the scurvy have had their livers almost without blood, and like a cow's udder. In some the gall-bladder was either empty or full of stones, or very bitter filth.

When the urine is thick, of a deep colour, and dyes linen yellow, it is a sign that the bile is obstructed, or the duct constricted with a spasm, whence the passage of the bile into the duodenum is hindered; whence it regurgitates by the lymphatic vessels into the blood and lymph, and produces a jaundice, which proceeds from an impeded secretion of the bile in the liver.

Sometimes the urine is imbuted with an oily matter, and is made without noise, there are various colours on the surface, chiefly bluish, and it adheres so strongly to the sides of the urinal, that it cannot be washed off with a lixivious liquor. This is a sign of the colligation of the fat: it shews a consumption, an atrophy, and an hætic. Sometimes it is observable in fevers, and the oleous matter is more plentiful in proportion to the fatness of the body.

When the urine abounds too much with a tartarous matter, which is known by its adhering to the sides of the chamber-pot, it is a sign of a disposition to the gravel and stone. When there is a small sand in the urine, it shews those disorders to be actually present. Sometimes shining yellow crystals are seen on the sides of the pot, which is a sign of arthritic or rheumatic pains. When the urine is bloody or whitish, from a mixture of pus loaded with a glutinous, thick, tenacious matter, of a bad smell, which sinks to the bottom, and does not dissolve by the agitation of the vessel, it is a certain sign of an ulcer in the kidneys or bladder. Sometimes, in the stone and ulcer of the bladder, it is like the white of an egg, and so tenacious that it will not divide, but fall from the vessel at once.

In a chronical and malignant gonorrhœa, not only the prostate, but often the bladder, is ulcerated; whence a thick and turbid urine, with a copious sediment, which, when thrown on the fire, has a most fetid smell. Likewise, in the stone in

the bladder, this, or its sphincter, is so eroded, that the urine is thick and branny, with small caruncles and filaments, which the vulgar take for worms. In the strangury, there is a frequent stimulus to make water, which is little and muddy, sharp and salt, with filaments; and then there is some spasmodic disorder affects the sphincter. If blood is mixed with the urine, like the washings of flesh or red-wine, but falls to the bottom, of a purple colour, it proceeds from the kidneys; but if it be of a brownish-black, it comes from the veins of the bladder.

*Incontinence of URINE.* This is a term used by medical writers to express an involuntary excretion of this liquor, whether it be incessantly, or in larger quantities at different intervals. This is of two kinds: in the one it is only in the night, in the time of sleep; and this arises merely from carelessness, and a bad habit: in the other, it depends on a paralytic affection of the sphincter of the bladder: and in this case it drops away continually from the patient; and this is therefore called by some a *stillicidium*. Authors also divide an incontinence of urine into the idiopathic and symptomatic: the idiopathic is a disease in itself, and depends upon the preceding causes; the symptomatic happens to different persons on different occasions, as a symptom of other complaints. It is common to dying persons; it is also very frequent to women who are big with child, and sometimes happens from violent sneezing, coughing, or laughing. The voiding of the urine involuntarily, and in the sleep, in infants, is not to be accounted a disease; but when this custom continues with them as they grow up, from idleness, or ill habit, it is at length to be considered as a disease, as they are by no means able to help it. Women who have suffered much in childbirth are often subject to an incontinence of urine afterwards, especially persons who have had their first child at an advanced age. People in years, who are subject to paralytic complaints, are also often afflicted with this troublesome complaint; and many who have been cut for the stone by persons not sufficiently skilled in the operation. Persons subject to the piles also sometimes fall into it, from the suppressions of their usual discharges, and sometimes from the tumours becoming fistulous, and reaching to the neck of the bladder. Impossibilities of the bladder will also occasion it, and violent external injuries.

An incontinence of urine, which happens only in the night, and is merely caused by a bad habit, and not of long standing, usually admits of a cure; but the *stillicidia* of urine, from paralytic disorders of the sphincter of the bladder, are very rarely cured, especially when they have been fixed some time upon the person. The involuntary voiding the urine in the night, in children, is to be cured, in a great measure, with punishment for the neglect, and by

# U R I

denying them much liquids after dinner-time ; by a proper diet ; the avoiding all diuretics, and the making water immediately before going to bed ; and when it has gone so far, that the tone of the parts is injured, the usual strengthening medicines are to be given, as in the following cases. When the incontinence of urine is occasioned by a paralytic weakness of the sphincter, nervous and strengthening medicines are the proper method of curing ; in this case, mastic, amber, nutmeg, and cinnabar, are found to be of great service, and pills or powders compounded of them, are an excellent general remedy to be given in small doses, two or three times a day. Externally, it is very proper to use by way of fomentation, decoctions of rosemary, sage, serpyllum, marjoram, and the like warm herbs in red wine. When the disease is occasioned by an imposthume or ulcer in the neck of the bladder, balsamics are to be given, as mastic, gum-juniper, and boiled turpentine ; but when it is owing to injuries received in child-birth, the manual operation of the surgeon is usually to be preferred to all internal medicines.

URINE, in agriculture, is of excellent use as a manure ; and for land, trees, &c. is preferable to dung ; as penetrating better to the roots, and removing divers infirmities of plants.

# U R S

URINOUS SALTS, are the same with what we otherwise call alkali salts, or alkalies. See ALKALI.

URN, *urna*, a kind of vase, of a roundish form, but biggest in the middle, like the common pitchers, now seldom used but in the way of ornament over chimney-pieces, in buffets, &c. The great use of urns among the ancients was to preserve the ashes of the dead after they were burnt ; for which reason they were called cineraria, and *urnæ cinerariæ*, and were placed sometimes under the tomb-stone whereon the epitaph was cut ; and sometimes in vaults in their own houses. Urns were also used at their sacrifices to put liquid things in.

URN was also a Roman measure for things liquid. See the article MEASURE.

UROCRITERIUM, a casting of water ; or giving judgment on diseases by the sight of the urine. See URINE.

URSA, in astronomy, the bear, a name common to two constellations of the northern hemisphere, near the pole ; distinguished by major and minor.

URSA *Major*, or the great bear, according to Ptolemy's catalogue, consists of 35 stars ; according to Tycho's, 56 ; but in the Britannic catalogue we have 215. The longitudes, latitudes, magnitudes, &c. are as follow.

| Names and Situations of the Stars.                 |  |  |  | Signs. | Longitude. | Latitude North. | Magn. |

URSULINES, in church-hiftory, an order of nuns, founded originally by St. Angela of Brefcia, in the year fifteen hundred thirty feven, and fo called from St. Urfula, to whom they were dedicated. They obferve the rules of St. Auguftine, and are chiefly noted for taking on them the education and inftruction of young maids: their monafteries are a kind of fchools where young ladies of the beft families receive their education. The habit of thefe religious is a gown of black ferge, or other ftuff, tied about with a girdle of black leather. The Urfulines are fpread chiefly over France and Italy; and their different obfervances in their feveral monafteries make them in truth fo many diftinct religious orders.

URSUS, the BEAR, in zoology. See the article BEAR.

URTICA, the nettle in botany. See the article NETTLE.

USANCE, *Ufo*, in commerce, is a determinate time fixed for the payment of bills of exchange, reckoned either from the day of the bills being accepted, or from the day of their date; and thus called becaufe regulated by the ufage and custom of the places whereon they ate drawn.

Bills of exchange are drawn at one or more ufances, either from fight or from date. The term is longer or shorter, according to the different countries. Ufance from London to any part of France, is thirty days; (this being declared to be a month, in regard to the exchanges, in this kingdom) whether the month has more or fewer in it. Ufance from London to Hamburgh, Amfterdam, Rotterdam, Middleburgh, Antwerp, Brabant, Zealand, and Flanders, and from thefe places to London, is one calendar month after the date of the bill. Ufance, from London to Spain and Portugal, and from thefe places

to London, is two calendar months after date. Usance from London to Genoa, Leghorn, Milan, Venice, and Rome, and from these places to London, is three months. See EXCHANGE.

Usance of Amsterdam upon Italy, Spain, and Portugal, is two months: upon France, Flanders, Brabant, Geneva, and upon any place in the seven United Provinces, is one month. Upon Francfort, Nuremburgh, Vienna, Ausburgh, Cologne, Leipzig, and other places of Germany, as also upon Hamburgh and Breslaw, is fourteen days after sight: two usances twenty-eight, and half usance seven.

Usance from Dantzic, Coningsberg, and Riga, upon Amsterdam, is at one month after sight; tho' it is common to draw from the first at forty days date, and from the others at forty one, but oftener at ten and eleven. And from Amsterdam on the said places at a month's date, without mentioning usance; tho' sometimes at forty and forty-one days; and sometimes on Breslaw at six weeks date. Most nations have generally agreed to allow the acceptor of a bill some small time for payment beyond that mentioned in the bill, termed days of grace or respite; but they generally disagree in the number and commencement of them.

USE, in law, the profit or benefit of lands and tenements; or a trust and confidence reposed in a person for the holding of lands, &c. that he to whose use the trust is made shall receive the profits.

Uses may be limited to a person and the wife he shall marry; and if the parties to a deed agree, and declare, that one of them shall make a feoffment, or levy a fine, to the use and intent that he shall hold the lands for his life, and after his decease another intail, and afterwards a third in fee simple, &c. the estate settles according to the uses in the deed.

The conveyances to uses are said to be of three sorts, viz. a covenant to stand seized; a feoffment, fine or recovery to uses; and a bargain and sale; which last a contingent use cannot be supported by, though it may by the two first.

A superstitious use, is where lands or goods are devised to a priest to pray for the souls of the dead, &c. in which case they become forfeited to the king: and where such an use is void, and the king cannot have the land, it shall not revert to the heir at law; but it may be applied to charity.

USES and Customs of the Sea, are certain maxims or rules which form the basis of maritime jurisprudence, by which the policy of navigation, and the commerce of the sea are regulated.

The uses and customs consist of three kinds of regulations: the first called the laws or judgments of Oleron; the second, regulations made by the merchants of Wisbuy, a city in the island of Gothland, in the Baltic, antiently much famed for commerce; and the third, a set of regulations made at Lubec, by the deputies of the Hanse towns.

USHER, an officer, or servant, who has the care and direction of the door of a court, hall, chamber, or the like.

In the king's household there are two gentlemen ushers of the privy-chamber, appointed to attend the door, and give entrance to persons that have admittance thither; four gentlemen-ushers, waiters; and eight gentlemen-ushers, quarter-waiters in ordinary.

USHER, also signifies an officer of the court of Exchequer, of which there are four who attend the barons and chief officers of that court at Westminster, as also juries, sheriffs, &c. at the pleasure of the court. There is also an usher of the court of chancery.

USHER of the Black-Rod, the eldest of the gentlemen-ushers, daily waiters at court, whose duty is to bear the rod before the king at the feast of St. George, and other solemnities: he has also the keeping of the chapter-house door, when a chapter of the order of the garter is sitting; and, in time of parliament, attends the house of peers, and takes delinquents into custody. He wears a gold badge, embellished with the ensigns of the order of the garter.

USNEA, in botany, a genus of mosses, wholly destitute of leaves, and composed only of long slender filaments, or stalks, which are usually solid, rigid, and of a cylindric figure. The whole plants are fixed in the manner of mistle to the barks of trees.

USQUEBAUGH, a strong compound liquor, chiefly taken by way of dram.

There are several different methods of making this liquor; but the following is esteemed one of the best: To two gallons of brandy, or other spirits, put a pound of Spanish-liquorice, half a pound of raisins of the sun, four ounces of currants, and three of sliced dates; the tops of baum, mint, savory, thyme, and the tops or the flowers of rosemary, of each two ounces; cinnamon and mace, well bruised, nutmegs, aniseeds; and coriander-seeds, bruised likewise, of each four ounces; of citron, or lemon and orange peel, scraped, of each an ounce: let all these infuse forty-eight hours in a warm place, often shaking them together: then let them stand in a cool place for a week: after which the clear liquor is to be decanted off, and to it is to be put an equal quantity of neat white port, and a gallon of canary; after which it is to be sweetened with a sufficient quantity of double-refined sugar.

USTION, in pharmacy, the preparing of certain substances by burning them.

USTULATION, *Ustulatio*, a word used by pharmacæutic writers to express the roasting or torrefying of humid or moist substances over a gentle fire, so as to render them fit for powdering. The same word is also used by some for what we call burning of wine.

**USUCAPTION**, *Usucaptio*, in the civil law, is an acquisition of the property of a thing, by a possession and enjoyment thereof for a certain term of years prescribed by law.

**USUFRUIT**, *Usus Fructus*, in the civil law, the use or enjoyment of any lands or tenements; or the right of receiving the fruits and profits of an inheritance; or other thing, without a power of alienating or changing the property thereof.

**USURER**, a person charged with a habit or act of usury. See the article **USURY**.

**USURIOUS CONTRACT**, is any bargain or contract, whereby a man is obliged to pay more interest for money than the statute allows.

**USURPATION**, in law, is an injurious using or enjoyment of a thing for continuance of time, that belongs of right to another.

**USURY**, *Usura*, in the general, denotes a gain or profit, which a person makes of his money, by lending the same; or it is an increase of the principal, exacted for the loan thereof; or the price a borrower gives for the use of a sum credited to him by the lender, called also interest; and in some ancient statutes, dry-exchange.

The word usury is generally taken in an evil sense, viz. for an unlawful profit which a person makes of his money; in which sense it is, that usury is forbidden by the civil and ecclesiastical, and even by the law of nature.

By stat. 12 Ann. c. 16, which is called, The Statute against Excessive Usury, it is ordained, that no person shall take for the loan of any money, or other thing, above the value of five pounds for the forbearance of one hundred pounds for a year; and so in proportion for a greater or lesser sum: and it is declared, that all bonds, contracts, and assurances, made for payment of any principal sum to be lent on usury, above that rate, shall be void; and that whosoever shall take, accept, or receive, by way of corrupt bargain, loan, &c. a greater interest than that last above-mentioned, shall forfeit treble the value of the money lent; and also, that scriveners, solicitors, and drivers of bargains, shall not take or receive above five shillings for the procuring the loan of one hundred pounds for one year, on pain of forfeiting twenty pounds, &c.

There can be no usury without a loan, between which and a bargain the court has distinguished: and though a person is to pay double the sum borrowed, &c. by way of penalty, for the non-payment of the principal debt, it is not usury; so it also is in respect to the grant of an annuity for lives, or on condition, where it exceeds the usual interest, and the proportion attending contracts of this kind. Even if one secures a large interest and principal, and it is at the will of the party who is to pay; or where it happens that both the principal money and extraordinary interest are in hazard, or that a per-

son may have less than his principal; as when a bond is made to pay money upon the return of a ship from sea, &c. either of these cases are not held to be usury.

In an action brought for usury, the statute made against it must be pleaded; and in pleading an usurious contract, as a bar to an action, the whole matter is to be set forth specially, because it lies within the parties own privity; yet on an information on the statute for making such contract, it is sufficient to mention the corrupt bargain generally; because matters of this kind are supposed to be privately transacted; and such information may be brought by a stranger. 1 Hawk. P. C. 248.

Likewise upon an information on the statute against usury, he that borrows the money may be a witness, after he has paid the same.

**UT**, a Latin term, literally signifying *as*, much used in stating of ratios and proportions.

**UT**, in music, the first of the musical notes, which, with the rest, was taken out of the hymn of St. John Baptist, *Ut queant laxis*, &c. See the article **SCALE**, **MUSIC**, &c.

**UTENSIL**, *Utenfile*, a little domestic moveable, belonging principally to a kitchen: such are pots, pans, &c.

Utensils are more particularly used in war, for the moveables which the host is obliged to furnish the soldiers, quartered with him; which are, a bed with bed clothes, a pot, and a spoon.

**UTERINE**, *Uterinus*, something belonging to the uterus, or womb of a woman.

*Furor UTERINUS*, in medicine, denotes a kind of madness, attended by lascivious speeches and gestures, and an invincible inclination to venery. See **FUROR**.

**UTERUS**, the womb, in anatomy, a hollow body, called also the matrix, of a form approaching to that of a pear, situated between the bladder and the rectum, and destined to the office of generation, for the containing the foetus. It is connected in the anterior part with the vagina, and at its lateral part by the ligaments, lata and rotunda, being loose in its hinder part.

In women not with child, the length of the uterus is about three inches; its breadth, in the upper part, being about two inches, and in the lower part one. Its thickness is about an inch and an half: in virgins, indeed, it is much smaller than this; but in women with child it is of a different size, according to the different time of gestation.

Anatomists divide it into two parts; the upper and broader part they call the fundus uteri, and the lower they call the cervix, into which it is that the vagina opens. See the article **VAGINA**.

The orifice, or, as it is otherwise called, the internal mouth of the womb, opens into the vagina.

in form of the glans penis in man: it is very small in virgins, but in women who have had children, or who are with child, it is larger; and in the last it is always closed up with a glutinous humour: in the time of delivery, it in a wonderful manner expands itself, so as to give passage to the child. See the article *DELIVERY*.

The substance of the womb is musculous, being composed of a various plexus of fleshy fibres, with a great number of vessels between. In women not with child, it is compact and firm; in those with child, it is spongy and sinuous, and is capable of wonderful dilatation, without any diminution of its thickness. It is covered externally with a membrane from the peritonæum; and internally, its cavity is lined with a porous and nervous membrane: this cavity is very small in virgins; and in women with child, the inner membrane almost entirely disappears.

The blood-vessels of the uterus are tortuous, and make a thousand anastomoses with one another: they open by a number of little mouths into the uterus and vagina, and are the sources of the menstrual discharge in women. See the article *MENSES*.

The arteries are of three kinds, viz. spermatics from the aorta; very large ones from the hypogastrics; and others from the hæmorrhoidal arteries. The veins of the uterus are also of three kinds, and of the same denominations: they have valves and are greatly larger than the arteries, especially in women with child. The nerves of the womb are from the intercostals, and those of the os sacrum. The lymphatics have long since been discovered in brutes; but Morgagni has of late years found them also in human subjects.

*UTILE*, a Latin term, signifying profitable or useful; in which sense it is sometimes used by English writers.

*UTRICULARIA*, in botany, a genus of plants, whose flower is monopetalous and ringent; the upper lip is flat, obtuse, and erect; the lower one is large, plane, and intire, with a heart-shaped palate and a corniculated nectarium: the stamina are two very short and incurved filaments, topped with small coherent antheræ: the fruit is a large, globose, unilocular capsule, containing a number of small seeds.

*UVARIA*, in botany, a genus of plants, whose flower consists of six lanceolated, sessile, patent petals; the stamina hath no filaments, but consists of a number of truncated oblong antheræ: the fruit is composed of many distinct, globose, pedunculated berries, affixed to an oblong receptacle; and the seeds are numerous.

*UVA URSI*, in botany, a name used by Tournefort for a species of arbutus. See the article *ARBUTUS*.

*UVEA*, in anatomy, the third or outermost coat of the eye. See *EYE*.

*VULCANO*, or *VOLCANO*, in natural history,

a burning mountain, or one that vomits forth fire, flame, ashes, cinders, &c.

As to the cause of vulcanos, it is found by experience, that there are several inflammable bodies, which, being mixed together in due proportion, will kindle into flame by fermentation alone, without the help of any fiery particles. Thus M. Lémery having covered up in the earth about fifty pounds of a mixture, composed of equal parts of sulphur and filings of iron, tempered with water; after eight or nine hours time, the earth, where it lay, vomited up flames. From this experiment, we see the true cause of the fire of *Ætna*, *Vesuvius*, and other burning mountains, which probably are made up of sulphur and some other matter proper to ferment with it, and take fire.

*VULGATE*, a very ancient Latin translation of the Bible, and the only one the church of Rome acknowledges authentic.

The ancient vulgate of the Old-Testament was translated almost word for word from the Greek of the *LXX*. The author of the version is not known, nor so much as guessed at.

*VULGATE of the New-Testament*. This the Romanists generally hold preferable to the common Greek text, in regard it is this alone, and not the Greek text, that the council of Trent had declared authentic. Accordingly, that church has, as it were, adopted that edition. The priests read no other at the altar, the preachers quote no other in the pulpit, nor the divines in the schools.

*VULNERARY*, an epithet given to remedies proper for the cure of wounds and ulcers.

All medicines of this intention are supposed both to cleanse and heal; that is, incarnate, or fill up with new flesh, all ulcerations and foulnesses. Under this head are ranged all such balsamics as are not only softening and adhesive, but also, by a peculiar activity, joined with a suitable configuration of parts, are apt to abrade and carry along with them what particles they lay hold on in their passage.

*VULTURE*, a genus of birds, the characters of which are as follow: there are four toes in each foot, and three of these are placed forwards: the neck is long, and almost bare of feathers: the legs are covered with feathers down to the feet, or nearly so; and under the throat there is a space covered with hairs instead of feathers; the head also, in many species, is naked, and has at the most only a downy matter on it, instead of feathers; and the under part of the wings is downy.

This genus comprehends the black vulture, the bætic vulture, the hare-catcher, the golden breasted vulture, the brown vulture, and Brazilian vulture.

*VULVA*, in anatomy, a name given as well to the uterus, or womb, as to the cunnus, or pudendum muliebre. See the articles *PUDENDUM* and *UTERUS*.

*VULVARIA*, in botany, the name of a species of

of *Chenopodium*. See the article *CHENOPODIUM*.

This plant has always been held in great esteem by the ancient as well as modern hiccobites, particularly on their festival days.

**UVULA**, in anatomy, a round, soft, spongy body, like the end of a child's finger, suspended from the palate, near the foramina of the nostrils, perpendicularly over the glottis. Its use is to break the force of the cold air, and prevent its entering too precipitately into the lungs. It is formed of a duplicature of a membrane of the palate; and is called,

by some authors, *columella*, and by others *gurgulio*.

It is moved by two pair of muscles, and suspended by as many ligaments.

**UVULARIA**, in botany, a genus of plants, whose flower consists of six oblong, erect, lanceolated petals, with an oblong nectarium cut into the base of each petal; the stamina are six very short filaments, topped with long erect antheræ; the fruit is an ovate-oblong trilocular capsule, containing many roundish compressed seeds.

## W.

**W**, The twenty-first letter of our alphabet, and is composed, as its name implies, of two V's. It was not in use among the Hebrews, Greeks, or Romans, but chiefly peculiar to the northern nations, the Teutones, Saxons, Britons, &c. But still it is not used by the French, Italians, Spaniards, or Portuguese, except in proper names, and other terms borrowed from languages in which it is originally used, and even then it is sounded like the single V.

This letter is of an ambiguous nature, being a consonant at the beginning of words, and a vowel at the end. It may stand before all the vowels except *u*, as *water*, *wedge*, *winter*, *wonder*: it may also follow the vowels *a*, *e*, *o*, and unites with them into a kind of double vowel, or diphthong, as in *saw*, *few*, *cow*, &c. It also goes before *r*, and follows *s*, and *th*; as in *wrath*, *swear*, *thwart*: it also goes before *h*, though in reality it is sounded after it, as in *when*, *what*, &c. In some words it is obscure, as in *shadow*, *widow*, &c.

**WACHENDORFIA**, in botany, a genus of plants, whose flower-cup is a bivalvular spatha; the corolla consists of six oblong petals; the three upper ones are erect, and the others open wide: the stamina are three slender declining filaments, terminated with incumbent antheræ: the fruit is an oval, obtuse, triquetrous capsule, with three cells, containing in each one hairy seed.

**WADD**, or **WADDING**, is a stopple of paper, hay, straw, or the like, forced into a gun upon the powder, to keep it close in the chamber; or to put up close to the shot, to keep it from rolling out.

**WAF**. To **waft** a ship, is to convoy her safe, as men of war do merchant ships. To make a **waft**, is to hang out some coat, sea-gown, or the like, on the main-throwds of the ship, as a signal for people to come aboard, and signifying that the ship is in great distress.

**WAFERS**, or **Sealing-WAFERS**, are made in the following manner: Take very fine flour, mix it with glair of eggs, isinglass, and a little yeast;

5 E

mingle

minge the materials; beat them well together, spread the batter, being made thin with gum-water, on even tin plates, and dry them in a stove; then cut them out for use.

You may make them of what colour you please, by tinging the paste with Brasil or vermilion for red; indigo or verditer, &c. for blue; saffron, turmeric, or gamboge, &c. for yellow. See the article *Sealing-Wax*.

**WAGGON**, a vehicle or carriage, of which there are various forms, accommodated to the different uses they are intended for.

The common waggon consists of the shafts or rads, being the two pieces which the hind horse bears up; the welds; the flotes, or cross-pieces, which hold the shafts together; the bolster, being that part on which the fore-wheels and the axle-tree turn, in wheeling the waggon across the road; the chest, or body of the waggon, having the staves or rails fixed thereon; the bales, or hoops, which compose the top; the tilt, the place covered with cloth, at the end of the waggon. For the principles on which this carriage is constructed, see the article **WHEEL**.

**WAGTAIL**, in ornithology; the name of two different species of motacilla. See the article **MOTACILLA**.

**WAIF**, or **WAFE**, in law, a term applied to such goods as a thief having feloniously stolen, on his being closely pursued, are waifed or left by the felon, which become forfeited to the king, or lord of the manor: and so it also is where a felon has the goods in his custody, and apprehending that pursuit is made, he flies, and leaves them behind him.

Though waif is properly applied to goods that are stolen, yet it may be also said of goods not stolen or taken away, as where a person is pursued with hue-and-cry as a felon, and he flies and leaves his own goods; in this case these shall be forfeited as stolen goods, or what are usually called fugitives goods.

**WAIF**, is also applied to things lost, and estrays, which, no owner appearing, are forfeited to the lord of the manor, after they have been cried and published in the markets.

**WAINSCOT**, in building, the timber-work that serves to line the walls of a room, being usually made in pannels, and painted, to serve instead of hangings.

It is usual, even in halls, to have wainscot breast high, by reason of the natural moistness of the walls. Some joiners put charcoal behind the pannels, to prevent the sweat of the stone and brick walls from ungluing the joints; others use wool for the same purpose; but the only sure way is to prime over the back sides of the joints with white-lead, Spanish brown, or linseed-oil.

The wainscotting with Norway oak, according

to Neve, (the workman finding stuff) is valued at 6 or 7 s. per yard square; plain square wainscotting, the workman finding deal, is valued at 3 s. and 3 s. 6 d. per yard. Ordinary bisection wainscotting, the workman finding deal, is worth 3 s. 6 d. and 4 s. per yard. Large bisection wainscotting, with Dantzic stuff, is valued at 6 or 7 s. per yard.

**WAIVE**, according to the different acceptation of the word, signifies to forsake; but in the law, it is especially applied to a woman, who, for any crime for which a man may be outlawed, is termed waive.

**WAIVER**, in law, denotes the passing by of a thing, or a refusal to accept thereof; and relates sometimes to an estate conveyed to a person, and sometimes to a plea.

It is held, where a particular estate is granted with a remainder over; in that case, he that has it, may not regularly waive it to the damage of him in remainder; though where one has the reversion, it is otherwise, for that is not hurt by such waiver.

**WAKE** of a Ship, is the smooth water astern when she is under sail: this shews the way she has gone in the sea, whereby the mariners judge what way she makes.

If the wake be right astern, they conclude she makes her way forwards; but if the wake be to leeward a point or two, then they conclude she falls to the leeward of her course. When one ship, giving chase to another, is got as far into the wind as she can, and sails directly after her, they say, she has got into her wake.

A ship is said to stay to the weather of her wake, when in her staying, she is so quick, that she does not fall to leeward upon a tack, but that when she is tacked, her wake is to the leeward; and it is a sign she feels her helm very well, and is quick of steerage.

**WAKE**, is the eve feast of the dedication of churches, which is kept with feasting and rural diversions.

**WAKE-ROBIN**, *Arum*, in botany. See the article **ARUM**.

**WALE**, or **WALES**, in a ship, those outermost timbers in a ship's side, on which the sailors set their feet in climbing up.

They are reckoned from the water, and are called her first, second, and third wale, or bend. See the article **SHIP**.

**WALE-KNOT**, a round knot, or knob, made with three strands of a rope, so that it cannot slip, by which the tacks, top-sail sheets, and stoppers, are made fast, as also some other ropes.

**WALE REARED**, on board a ship, a name the seamen give to a ship, which, after she comes to her bearing, is built straight up: this way of building, though it does not look well (nor is, as the seamen term it, ship-shaped) yet it has this advantage, that

that a ship is thereby more roomy within board, and becomes thereby a wholesome ship at sea, especially if her bearing be well laid out.

**WALK**, in gardening, an ornamental and useful part of a garden, differing from an alley by being wider. See **ALLEY**.

Walks are either strait or serpentine; the materials of which they are formed are gravel, sand, or grass; but where gravel or sand cannot be procured they are sometimes laid with powdered coal, sea-coal ashes, and sometimes with powdered brick, but none equals those made with gravel: and in order to the laying those kind of walks, it is very proper to fill the bottom with lime, rubbish, flint stones, coarse gravel, or other rocky materials, which will be of service to prevent weeds from growing thro' the gravel, and to hinder worm-casts; this bottom should be ten inches or a foot thick, over which the coat of fine gravel, mixed with a due proportion of loam, should be laid, to the thickness of ten inches. The common allowance for a gravel walk of five feet breadth is an inch in the crown, so that if a walk be twenty feet wide, it should be four inches higher in the middle than on each side.

When a walk has been evenly laid, trodden down, and raked, it should then be rolled well both in length and width; and in order to make them more firm, it will be necessary to give them three or four water-rollings, that is, they should be rolled when it rains very fast; this will cause the gravel to bind, so that when the walks come to be dry, they will be as hard as terrace.

Gravel walks are not only very necessary near the house, but there should always be one carried quite round the garden, because being soon dry after rain, they are proper for walking on in all the seasons; but then these should be but few, and those adjoining to the house ought to be large in proportion to the size of the house and garden: the principal of these walks should be elevated, and carried parallel with the house so as to form a terrace; this should extend itself each way in proportion to the width of the garden, so that from this there may be a communication with the side walks, whereby there may be dry walking all round the garden. For farther particulars concerning gravel walks, see the article **GRAVEL**.

Sand walks are also frequently made in gardens; these are less expensive in the making, and also in keeping in order than those of gravel, for as the greatest part of the walks which are made in modern gardens twist about in an irregular serpentine manner, it would be very difficult to keep them handsome if they were laid with gravel, especially where they are shaded by trees; for the dripping of the water from their branches in hard rains is apt to wash the gravel in holes and render the walks very unsightly, therefore those walks which go through woods and plantations are much better if laid with

sand, which will be dry and wholesome, and whenever they appear mossy, or any weeds begin to grow on them, if they are scuffled over with a Dutch hoe in dry weather and raked smooth, it will destroy the moss and weeds, and make the walks appear as fresh and handsome as when first laid.

The breadth of these walks should be proportioned to the size of the ground, which, in a large extent, may be twelve or fourteen feet wide, but in small gardens five or six will be sufficient.

The ground being traced out in the manner as the walks are designed, the earth should be taken out of the walk and laid in the quarters; the depth of this must be proportioned to the nature of the soil, for where the ground is dry, the walks need not be elevated above the quarters, so the earth may be taken out four or five inches deep in such places; but where the ground is wet, the bottom of the walks need not be more than two inches below the surface, that the walks may be raised so high as to throw off the wet into the quarters, which will render them more dry and healthy to walk on: after the earth is taken out, the bottom of the walks should be laid with rubbish, coarse gravel, &c. to the thickness of five or six inches, and beaten down close, to prevent the worms from working through it; then the sand should be laid upon this about three inches thick, and after treading it down, it should be raked over to level and smooth the surface: the sand that is fitting for this purpose should be such as will bind, otherwise it will be very troublesome to walk on them in dry weather; for if the sand be of a loose nature, it will be moved by strong gales of wind, and in dry weather will slide from under the feet; and if it is too much inclinable to loam, it will also be attended with as ill consequence as that which is too loose, for this will stick to the feet after every rain; so that where sand can be obtained of a middle nature, it should always be preferred.

Grass walks in gardens were formerly held in great esteem, and were looked upon as necessary ornaments to a garden; but of late years they have been much less regarded; for these long narrow slips of grass are far from being pleasing to the eye, and are for the greatest part of the year useless, being generally too damp for persons of tender constitutions to walk on; and whenever they were constantly used, they became bare in the places frequently trodden, so were rendered more unsightly; and as the intention of walks in gardens is to have at all seasons a dry communication through them for exercise and recreation, grass walks were very improper, because every shower of rain made them so wet, as not to be fit for use for a considerable time, and the dews rendered them too damp to walk on either in the morning or evening, and if they are not kept constantly close mowed, then they become not only unhealthful but troublesome to the feet;  
besides

besides, whenever the ground is so dry, as that persons may with safety walk upon grass, the lawns and other parts of verdure in gardens are better adapted for use than any of these formal stiff walks, which were so much esteemed in the last age.

**WALK**, in the manege, is the slowest, and least raised of all a horse's goings. It is performed by a horse's lifting up his two legs on a side, the one after the other, beginning with the hind leg first. Thus, if he leads with the legs of the right side, then the first foot he lifts is the far hind-foot, and in the time he is setting it down, (which in a step is always short of the tread of his fore-foot on the same side) he lifts his far fore-foot, and sets it down before his near fore-foot. Again, just as he is setting down his far fore-foot, he lifts up his near hind-foot, and sets it down again just short of his near fore-foot; and just as he is setting it down, he lifts his near fore-foot, and sets it down beyond his far fore-foot.

**WALL**, in architecture, the principal part of a building, as serving both to inclose it, and support the roof, floors, &c.

Walls are distinguished into various kinds, from the matter whereof they consist, as plastered or mud walls, brick-walls, stone-walls, flint, or boulder walls, and boarded walls. In all which these general rules are to be regarded. 1. That the right angle therein depending is the true cause of all stability, both in artificial and natural position. 2. That the massiest and heaviest materials be the lowest, as fitter to bear than to be borne. 3. That the walls, as they rise, diminish proportionably in thickness, for ease both of weight and expence. 4. That certain courses or ledges, of more strength than the rest, be interlaid, like bones, to strengthen the whole fabric.

Brick-walls are the most important and usual amongst us. In these, particular care is to be taken about laying of the bricks; that in summer they be laid as wet, and in winter as dry, as possible, to make them bind the better with the mortar: that in summer, as fast as they are laid, they be covered up, to prevent the mortar, &c. from drying too fast: that in winter they be covered well to protect them from rain, snow, and frost, which are all enemies to mortar: that they be laid joint on joint in the middle of the walls as seldom as may be: but that good bond be made there as well as on the outside. Care is to be taken that the angles be firmly bound, which are the nerves of the whole edifice. In order to which, in working up the walls of a building, it is not advisable to raise any wall above eight feet high, before the next adjoining wall be brought up to it, that so good bond may be made in the progress of the work; it may be worth notice, that a wall a brick and a half thick, with the joint, will be in thickness fourteen inches, or very near; whence 150 or 160 bricks will lay a yard square measured upon the face of the building; and to the square of

ten feet are usually allowed 1700 or 1800 bricks. Flint, or boulder walls, are much used in some parts of Sussex and Kent, for fence-walls, round courts, gardens, &c. A right and left-handed man fits well for this work, as they have a hod of mortar poured down upon the work, which they part between them, each spreading it towards himself, and so they lay in the flints. The mortar for this work must be very stiff.

**WALL**, in gardening. Of all materials for building walls for fruit-trees, brick is the best; it being not only the handsomest, but the warmest and kindest for the ripening of fruit; and affording the best conveniency for nailing, as smaller nails will serve in brick than will in stone walls, where the joints are larger; and if the walls are coped with free-stone, and stone pilasters or columns at proper distances, to separate the trees, and break off the force of the winds, they are very beautiful, and the most profitable walls of any others.

In some parts of England there are walls built both of brick and stone, which are found very commodious. The bricks of some places are not of themselves substantial enough for walls; and therefore some persons, that they might have walls both substantial and wholesome, have built these double, the outside being of stone, and the inside of brick: but there must be great care taken to bind the bricks well into the stone, otherwise they are very apt to separate one from the other, especially when frost comes after much wet.

There have been several trials made of walls built in different forms; some of them having been built semicircular; others in angles of various sizes; and projecting more towards the north, to screen off the cold winds: but there has not as yet been any method which has succeeded near so well as that of making the walls strait, and building them upright. Where persons are willing to be at the expence, in the building of their walls substantial, they will find it answer much better than those which are slightly built, not only in duration, but in warmth: therefore a wall two bricks thick, will be found to answer better than one of a brick and a half: and if in building of garden-walls they are grouted with soft mortar, to fill and close all the joints, the walls will be much stronger, and the air will not so easily penetrate, as it does through those which are commonly built.

For the aspect or situation of garden-walls, see the article **EXPOSURE**.

**Hot-WALL**. See the article **FORCING**.

**WALL-FLOWER**, *Leucorum*, in botany, is included by Linnæus among the cheiranthus. See **CHEIRANTHUS**.

Of wall-flowers there are several varieties; as the yellow wall-flower, the bloody wall-flower, the white wall-flower, and the double yellow, white, and bloody wall-flowers: they are easily propagated from

from seeds (except the double ones) either by sowing when the seeds are ripe, or in the spring; those which produce double flowers are raised from slips, which should be planted in a shady situation, either in April or May, which, when sufficiently rooted, may be transplanted where they are intended to blow; these flowers appear in the spring, and are much admired for their fragrantcy.

**WALNUT-TREE**, *Juglans*, in botany, a genus producing male and female flowers on the same tree; the male flowers are disposed in an oblong, cylindrical, imbricated amentum; the corolla of each flower is divided into six plane, equal, and elliptic parts, in the center of which is situated a number of very short filaments, topped with erect, acuminate antheræ; the female flowers grow in small clusters, sitting close to the branches; the corolla of each is divided into four erect pointed segments; the fruit is a large, oval, dry, and unilocular drupe, inclosing a large oval nut with netted furrows, containing a kernel with four lobes, which are variously furrowed.

The walnut-tree grows to a very large size; the trunk is covered with a thick bark of a greenish ash colour, and smooth; but when it grows old, it is full of longitudinal indentures; the leaves are disposed in wings, five, six, or seven adhering to one rib, consisting of conjugations with a single leaf at the end; at first they are tender, reddish, and have a sweet smell, but when they are full grown they are smooth, slightly serrated, of a beautiful green, with a strong scent, and of an astringent taste: the flowers appear late in the spring, and the fruit is ripe in autumn.

There are different kinds of walnuts, as the large walnut, the thin-shelled walnut, the hard-shelled walnut, the late ripe walnut, the French walnut, the double walnut; beside these there are several sorts of American walnuts; but the two first mentioned kinds are most commonly propagated for their fruit and timber. The trees are raised from the nuts; and in order to obtain such as are good, choice should be made of those which have the sweetest kernel and thinnest shell. When the nuts are ripe they should be gathered and preserved in sand till February, at which time they may be planted in good fresh land that is not hot and dry, at the distance of about six inches and three in depth; at the end of two years the plants may be taken out of the seed beds, pruning off only the downright roots, without cutting the branches, and transplanted; but this is to be understood of those which are planted for the sake of the fruit only; but if they are designed for timber, it is better to plant the nuts where the plants are intended to perfect themselves, without any removal. The best season for transplanting walnut-trees is as soon as the leaves begin to decay, which may be done till they are eight or nine years old; but they will not grow so

large or continue so long as those which are removed young. These trees delight in a good rich loam where there is a proper depth; they should be placed at least forty feet asunder when any regard is had to the fruit, but when for timber, they should stand nearer each other, because it promotes their upright growth.

The wood of the walnut-tree is well known for vaneeing or covering curious cabinets, chests of drawers, and the like; that of the black Virginian walnut is most esteemed for these purposes, it being of a more beautiful grain, and more finely variegated than that of the common sort, it is also more durable, being rarely infected with insects of any kind, which may proceed from its extraordinary bitterness; but it is not fit for buildings of strength, being of two brittle a nature.

The inner bark of the walnut-tree is a strong vomit, but the catkins are more gentle; some account the leaves an excellent cataplasm against the gout; the juice of the root is a violent purge, unless it proceeds from the wounded root in February, and then it is recommended in chronic diseases, especially in the gout, gravel, and head-ach; the green outer rind is astringent, and is said by some to have an emetic faculty, when fresh; the pith powdered and given to a dram, is good against the cholic and fluxes of the belly.

**WALRUS**, in zoology, the English name of the phoca, with canine teeth exerted. See the article PHOCA.

This is much larger than the sea-calf, or phoca, with the canine teeth covered; growing to the size of the largest ox; the head is very large, and almost of a rounded figure; the eyes are large and prominent; there are no ears, but only an aperture on each side of the head, of an oblong form, and not very large; the nose is obtuse; the nostrils large, and the creature contracts and dilates them at pleasure; the mouth is very large, and the upper part of it furnished with thick and cartilaginous whiskers; the tongue is short, the canine teeth of the upper jaw are of an enormous length and size, and they hang downwards and forwards toward the breast; the creature uses these strange weapons to climb upon the ice, and to hang itself to the rocks in its getting on shore to sleep.

**WALTHERIA**, in botany, a genus of plants, whose flower consists of five heart-shaped spreading petals, and the same number of short stamina joining at their base: the fruit is an oval unilocular capsule, containing an obtuse seed, which is broadest at the top.

**WANLASS**, in hunting. Driving the wanlass, is the driving of deer to a stand, that the lord may have a shoot, which is one of the customary services of fiefs.

**WAPENTAKE** (from the Saxon) the same with what we call a hundred, and more especially

in the northern counties beyond the river Trent. There have been several conjectures as to the original of the word; one of which is, that anciently musters were made of the armour and weapons of the inhabitants of every hundred; and from those that could not find sufficient pledges of their good abearing, their weapons were taken away, and given to others; whence it is said this word is derived.

**WAR**, a contest or difference between princes, states, or large bodies of people; which not being determined by the ordinary measures of equity and justice, is referred to the decision of the sword.

*Holy WAR*, was that anciently maintained by leagues and croisades, for the recovery of the Holy-land. See **CROISADE**.

**WARD**, in law-books, a word of divers significations: thus, a ward in London, is a part of the city committed to the special charge of one of the aldermen of the city. There are twenty-six wards in London, which are as hundreds, and the parishes thereof as towns. A forest is also divided into wards, and so are most of our hospitals.

**WARD**, **WARDA**, or **WARDAGIUM**, is also used, in our ancient writings, for the custody of a town or castle, which the tenants and inhabitants were bound to keep at their own charge.

**WARD-HOOK**, or **WADD-HOOK**, in gunnery, a rod or staff with an iron end turned serpent-wise, or like a ferew, to draw the wadding out of a gun when it is to be unloaded.

**WARDEN**, or **GUARDIAN**, one who has the charge, or keeping of any person, or thing, by office. See the article **GUARDIAN**.

Such is the warden of the Fleet, the keeper of the Fleet-prison; who has the charge of the prisoners there, especially such as are committed from the court of Chancery for contempt.

Warden, in an university, is the head of a college, answering to what in other colleges we call master thereof.

Warden, or lord-warden of the cinque-ports, is a governor of these noted havens; who has the authority of an admiral, and sends out writs in his own name.

Warden of the Mint, is an officer whose business it is to receive the gold and silver bullion brought in by the merchants, to pay them for it, and oversee the other officers. He is called keeper of the exchange and mint.

**WARDMOTE**, in London, is a court so called which is kept in every ward in the city, answering to the *curiata comitia* in antient Rome. See the article **COURT**.

**WARDROBE**, a closet or little room, adjoining to the bed-chamber, serving to dispose and keep a person's apparel in; or for a servant to lodge in, to be at hand to wait, &c.

Wardrobe, in a prince's court, is an apartment

wherein his robes, wearing apparel, and other necessities, are preserved under the care and direction of proper officers; as the master of the wardrobe, clerk, &c. of the wardrobe.

**WARN**, in law, is to summon a person to appear in a court of justice. See **SUMMON**.

**WARNING PIECE**, in the military art, is the gun which is fired every night about sun-set, to give notice to the drums and trumpets of the army to beat and sound a retreat or tattoo, which is likewise called, setting the watch. See **RETREAT**.

**WARNING-WHEEL**, in a clock, is the third or fourth, according to its distance from the first wheel. See **CLOCK**.

**WARP**, in the manufactures, is the threads, whether of silk, wool, linen, hemp, &c. that are extended lengthwise on the weaver's loom; and across which the workman, by means of his shuttle, passes the threads of the woof, to form a cloth, ribband, fustian, or other matter.

For a woollen stuff to have the necessary qualities, it is required that the threads of the warp be of the same kind of wool, and of the same fineness throughout; that they be sized with Flanders or parchment size, well prepared, and that they be in sufficient number with regard to the breadth of the stuff to be wrought.

*To WARP a Ship*, is to shift her from one place to another, when the wind and tide will permit it without danger.

**WARRANT**, an act, instrument, or obligation, whereby a person authorises another to do something which he otherwise had not a right to do.

Warrant of attorney, is that whereby a man appoints another to do something in his name, and warrants his action.

It seems to differ from a letter of attorney, which passes under hand and seal of him who makes it, before credible witnesses; whereas warrant of attorney, in personal, mixed, and some real actions, is put in of course by the attorneys for the plaintiffs or defendants.

**WARRANTY**, *Warrantia*, a promise or covenant by deed, made by the bargainer for himself and his heirs, to warrant and secure the bargainee and his heirs against all men for enjoying the thing agreed on between them.

**WARRANTIA CHARTÆ**, a writ that lies for a person who is infeoffed in lands and tenements, with clause of warranty, and is impleaded in an assize, or writ of entry, wherein he cannot vouch or call to warranty. See **VOUCHER**.

**WARRANTIA DIEI**, a writ which lies in case where a man, having a day assigned to appear personally in court to an action, wherein he is sued, is, in the mean time, by commandment employed in the king's service; so that he cannot come at the day assigned.

It is directed to the justices, ordering them not to find or record him in default.

**WARREN**, *Warrena*, a franchise, or place privileged, either by prescription or grant from the king, to keep beasts and fowl of warren in; as rabbits, hares, partridges, pheasants, &c.

By statute 21 Edw. III. a warren may lie open, and there is no need of closing it in, as there is a park.

In the setting up a warren, great caution is to be used for the fixing upon a proper place, and a right situation. It should always be upon a small ascent, and exposed to the east or the south. The soil that is most suitable, is that which is sandy; for when the soil is clayey or tough, the rabbits find greater difficulty in making their burrows, and never do it so well; and if the soil be boggy or moorish, there would be very little advantage from the warren, for wet is very destructive of these animals.

All due precautions must be taken, that the warren be so contrived, that the rabbits may habituate themselves to it with ease. Many would have it, that warrens should be enclosed with walls; but this is a very expensive method, and seems not necessary nor advisable; for we find but very few that are so, and those do not succeed at all the better for it.

**WART**, *Verruca*, in surgery, a little round hard excrescence arising from the flesh like a pea.

A wart begins at the cutis, and seems to be either an efflorescence of the serum of the blood, which hardening in the surface of the skin, makes a dry tumour; or else some small luxuriancy of the little arteries of the cutis, which thrust themselves out, making a petty sarcoma, which we call a soft wart. See the article **SARCOMA**.

According to the variety of the tumour, it is sometimes whole with a smooth surface, and sometimes chapped and uneven.

The method of cure which deserves to be first mentioned, is by ligature or vincture; this is performed upon such of these excrescences as are slender about the roots, and in a manner pendent, by firmly tying about them a horse-hair, or a silken or linen thread; the warts, being thus deprived of the juices which nourish them, through a constriction of the vessels by the ligature, gradually wither and fall away.

Another method of cure, is the surgeon's instrument, with which the wart is taken up by a hook or forceps, and then very nicely separated by the scissars. The wound is treated for some time with an application of the lapis infernalis, or some other corroding medicine, that, if any part of a root should remain, from which a new tubercle might arise, it might be consumed and destroyed.

The cure by caustics is best performed by cutting off the hard upper part of the wart, with a razor or scissars, and then surrounding its bottom with a circle of wax to prevent the spreading of the remedies;

to touch it daily with oil of tartar, spirit of salt, aqua fortis, or butter of antimony. See **CAUSTIC**.

The cure by cautery is performed by choosing a cautery of a proper size, and with that burning down to the root of the wart. This is the most painful of all the methods of extirpating these excrescences, but the pain is but for a moment, and the warts extirpated this way never return. See **CAUTERY**.

The cure by evulsion, is performed by anointing them with softening ointment, and then seizing them artfully between the thumb and fore-finger, and forcibly wrenching them out. This is a mountebank method, and a bad one; for it is not only very painful, but the warts commonly grow up again.

When warts are found to look livid and blue, it is best to let them alone entirely; because, when irritated, they frequently degenerate into a cancer. See **CANCER**.

**WART-WORT**, *Tithymalus*, in botany. See **TITHYMALUS**.

**WASH**, among distillers, the fermentable liquor used by the malt-distillers. See **DISTILLERY**.

It should be about the strength of the ten shilling small-beer; and if the spirit be expected fine, it had better be too thin than too thick. It is only made by mixing the water hot with the malt ground into meal. If the water be too hot, the mixture will become gluey; and if too cool, a part of the virtue of the malt will be lost. Under the right application of the water is to be considered the proper manner of agitating the mass, so that all the parts of the aqueous fluid may come fully and freely in contact with the soluble particles of the subject.

When once the water is well saturated by standing on the malt a proper time, it must be drawn off, and fresh poured on, till at length the whole virtue, or all the fugary sweetness of the malt, is extracted, and nothing but a fixed husky matter remains behind, incapable of being farther dissolved by the action of hot or boiling water; or of being advantageously washed or rinsed out by the bare affusion of cold.

This artificial and external agitation or stirring about of the mass, is necessary, not only in the common way of brewing for the malt-distillery, but also in that more expeditious way, now in use with some, of reducing the operations of brewing and fermenting to one, and grinding the malt to a fine meal, which is to be kept in the wash during the whole time, and even put into the still with it and worked together.

The stirring may be repeated to great advantage more than once in each operation, as at the affusion of every parcel of fresh water, in the common way, and at any shortly distant times in the short way, in which it is of greater service.

The action of fermentation works such a change

in the body of the tincture or solution, called the wash, as to render it separable by distillation, into parcels of matter that are specifically different, and of a nature entirely foreign to what the same liquor would have yielded without the fermentation. See FERMENTATION.

**WASHING**, in painting, is when a design, drawn with a pen or crayon, has some one colour laid over it with a pencil, as Indian-ink, bistre, or the like, to make it appear the more natural, by adding the shadow of prominences, apertures, &c. and by imitating the particular matters, whereof the thing is supposed to consist.

Thus they wash with a pale red to imitate brick and tile; with a pale Indian-blue, to imitate water and slate; with green, for trees and meadows; with saffron or French-berries, for gold or brass; and with several colours for marbles. These washes are usually given in equal tints or degrees throughout; which are afterwards brought down and softened over the lights with fair water, and strengthened with deeper colours for the shadows.

Some colours are of such a gritty, sandy nature, that it is impossible to grind them so fine as some curious works require; therefore, in order to get forth the flour and fineness of the colour, it must be washed, which is done thus: Take what quantity of colour you please to wash, and put it into a vessel of fair water; stir it about till the water be all coloured therewith, and if any filth swim on the top of the water, scum it clean off; and, when you think the grossest of the colour is settled at the bottom, then pour off that water into another earthen vessel, that is large enough to contain the first vessel full of water four or five times; then pour more water into the first vessel, and stir the colour that remains till the water be thick; and after it is a little settled, pour the water also into the second vessel, and fill the first vessel again with water, stirring it as before; continue to do this till you find all the finest of the colour drawn forth, and none but coarse gritty stuff remain in the bottom; then let this water in the second vessel stand to settle till it is perfectly clear, and that all the colour be sunk to the bottom; which when you perceive, then pour the water clear from it, and reserve the colour in the bottom for use, which must be perfectly dried before you mix it with oil to work.

The colours thus ordered, are red lead, blue and green bice, verditer, blue, green smalt, and Spanish brown, when you would cleanse it well from stones for some fine work, as also yellow oker, when you intend to make gold size of it.

**WASHING of Ores**, the purifying an ore of any metal, by means of water, from earths and stones, which would otherwise render it difficult of fusion; this operation Cramer orders to be done as follows. Break the ore to a coarse powder in an iron mortar, weigh twenty or thirty docimaetical centners of it,

put them into the washing-trough, and pour some water upon them, that the ore may be thoroughly moist; then have a vessel full of water, the diameter of which must be a little larger than the length of the trough; take the trough with the left hand, by the top of the hinder part, and dipping it horizontally into the water, move it gently with the right-hand from the fore-part of the trough, which is always to be made the shallower part of it, toward the hinder part, which is deeper; then take out the trough, and incline it a little on the fore-part, that the water may run out, and the heavier metallic part remain at the bottom; repeat this several times till the remains at the bottom of the trough are quite pure, if the stone in which the ore is lodged, be too hard for powdering in its natural state, as the flinty and debased crystalline ones commonly are, the whole must be calcined, and quenched in cold water several times over, and afterwards powdered and washed in this manner: when it is thus washed, assay a centner of it, and from the bead of metal this yields, it will be easy to estimate the value of the ore.

**WASHING, or WASHES**, among goldsmiths, coiners, &c. are the lotions whereby they recover the particles of gold and silver out of the sweep, i. e. ashes, earths, sweepings, &c.

This is either performed by simply washing them again and again, or by putting them in the washing-mill.

To make one of these washes, they not only gather together the ashes of the furnaces, and sweepings of the work-houses, but they also break and pound the old earthen crucibles and the very bricks whereof the furnaces are built; little particles of gold, &c. being found to stick to them by the crackling natural to those metals, when in their last degree of heat.

These matters, being ground and mixed together, are put in large wooden basons, where they are washed in several waters; which run off by inclination into troughs underneath; carrying with them the earth, and the insensible particles of the metals, and only leaving behind them the larger and more considerable ones which are visible to the eye, and taken out by the hand without more trouble.

To get out the finer parts gone off with the earth, they use quicksilver and a washing-mill. This mill consists of a large wooden trough, at the bottom of which are two metalline parts, serving as mill-stones; the lower being convex, and the upper, which is in form of a cross, concave.

At top is a winch placed horizontally, which turns the upper piece round; and at bottom, a bung to let out the water and earth, when sufficiently ground.

To have a wash, then, the trough is filled with common-water, into which they cast thirty or forty pounds

pounds of quicksilver, and two or three gallons of the matter remaining from the first lotion. Then turning the winch, they give motion to the upper mill-stone, which grinding the matter and the quick-silver violently together, the particles of gold and silver become the more easily amalgamated therewith. This work they continue for two hours, when, opening the bung, the water and earth run out, and a fresh quantity is put in.

The earths are easily thus passed through the mill three times, and the same quantity of mercury usually serves all the three times. When there is nothing left in the mill but the mercury united with the gold or silver which it has amalgamated, they take it out, and washing it in divers waters, they put it in a ticken-bag, and lay it in a press to squeeze out the water, and the loose quick-silver; the remaining quick-silver they evaporate by fire, in a retort, or an alembic. The metal which remains they refine with lead, or part it with aqua fortis. See ASSAYING.

WASP, in zoology, the black apis, with four yellow circles on the body. See the article APIS.

WASP-FLY, the vespæform asilus, with the antennæ longer than the head. See the article ASILUS.

WAST, or WASTE, *Vastum*, in law, has divers significations. It is used for a spoil, made either in houses, woods, lands, &c. by the tenants for life, or for years, to the prejudice of the heir, or of him in reversion or remainder.

Upon this the writ of waste is brought for the recovery of the thing wasted, and treble damages.

WASTE of the Forest, is properly where a man cuts down his own woods within the forest, without licence of the king or lord chief justice in eyre.

WASTE is also taken for those lands which are not in any man's occupation, but lie common.

They seem to be so called, because the lord cannot make such profit of them, as of his other lands, by reason of the use others have thereof, for passing to and fro. Upon this none may build, cut down trees, &c. without the lord's licence.

WASTE of a Ship, is that part of her between the main and foremast.

WASTE-BOARDS, are boards sometimes set upon the side of a boat, or other vessel, to keep the sea from breaking into her.

WASTE-CLOTHS, in a ship of war, the same with fights. See the article FIGHT.

WATCH, in the art of war, a number of men posted at any passage, or a company of the guards who go on the patrol. See the articles GUARD and PATROL.

Also a person posted as a spy in any place, to have an eye thereto, and to give notice of what passes. A watch is properly intended for the ap-

prehending of rogues in the night, as ward is for the like purpose in the day time; and for default to watch and ward, the township, &c. is punishable. It is ordained, that in all towns between Michaelmas day and the day of Ascension, there shall be night-watches kept in each city, with six men at every gate, and six or four in a town. Also every borough is to have twelve men to watch therein, or otherwise in proportion to the number of the inhabitants in the place, from sun-set, to sun-rising, who are to arrest strangers suspected, and disturbers of the peace, &c. and may justify the detaining of them till the morning; or they may deliver them to the constable, in order to be carried before a justice.

At sea, the term watch denotes a measure or space of four hours, because half the ship's company watch, and do duty in their turns, so long at a time; and they are termed star-board watch, and lar-board watch.

WATCH is also used for a small portable movement or machine for the measuring of time; having its motion regulated by a spiral spring. See the article SPRING.

Watches, strictly taken, are all such movements as shew the parts of time; as clocks are such as publish it, by striking on a bell, &c. But, commonly, the name watch is appropriated to such as are carried in the pocket, and clock to the large movements, whether they strike or not. See the article CLOCK.

The several members of the watch part are, 1. The ballance, consisting of the rim, which is its circular part; and the verge, which is its spindle, to which belong the two pallets or levers that play in the teeth of the crown-wheel. 2. The potence, or pottance, which is the strong stud in pocket-watches, whereon the lower pivot of the verge plays, and in the middle of which one pivot of the ballance-wheel plays; the bottom of the potence is called the foot, the middle part the nose, and the upper part the shoulder. 3. The cock, which is the piece covering the ballance. 4. The regulator or pendulum spring, which is the small spring in new pocket-watches, underneath the ballance. 5. The pendulum, whose parts are the verge, pallets, cocks, and the bob. 6. The wheels, which are the crown-wheel in pocket pieces, and the swing-wheel in pendulums, serving to drive the ballance or pendulum. 7. The contrate-wheel, which is that next the crown wheel, &c. and whose teeth and hoop lie contrary to those of other wheels; whence the name. 8. The great or first wheel, which is that the fusee, &c. immediately drives: after which are the second wheel, third wheel, &c. 9. Lastly, between the frame and dial-plate, is the pinion of report, which is that fixed on the arbor of the great wheel, and serves to drive the dial-wheel, as that serves to carry the hand.

*Spring, or Pendulum WATCHES*, are pretty much upon the same principle with pendulum clocks, whence their denomination.

If a pendulum describing little arches of a circle make vibrations of unequal lengths, in equal times, it is by reason it describes the greater with greater velocity. For the same reason a spring put in motion, and making greater or less vibrations, as it is more or less stiff, and as it has a greater or less degree of motion given it, performs them nearly in equal times. Hence, as the vibrations of the pendulum had been applied to large clocks to rectify the inequality of their motions; so, to correct the unequal motions of the ballance of watches, a spring is added, by the isochronism of whose vibrations the correction is to be effected.

The spring is usually wound into a spiral, that, in the little compass allotted it, it may be as long as possible, and may have strength enough not to be mastered and dragged about by the inequalities of the ballance it is to regulate.

The vibrations of the two parts, viz. the spring and ballance, should be of some length; only so adjusted, as that the spring, being more regular in the length of its vibrations than the ballance, may on occasion communicate its regularity thereto.

The invention of spring or pocket watches, is owing to the artists of the present age. It is true, we find mention made of a watch presented to Charles V. in the history of that prince; but this in all probability was no more than a kind of a clock to be set on a table, some resemblance whereof we have still remaining in the ancient pieces made before the year 1670.

In effect, it is between Dr. Hooke and Mr. Huygens, that the glory of this excellent invention lies, but to which of them it properly belongs, is greatly disputed; the English ascribe it to the former, and the French, Dutch, &c. to the latter. Mr. Derham, in his *Artificial Clock-maker*, says plainly that Dr. Hooke was the inventor; and adds, that he contrived various ways of regulation. One was with a load-stone: another with a tender straight spring, one end whereof played backwards and forwards, with the ballance; so that the ballance was to the spring, as the bob to a pendulum; and the spring, as the rod thereof. A third method was with two ballances, of which there were divers sorts, some having a spiral spring to the ballance for a regulator, and others without. But the way that prevailed, and continues in mode, was with one ballance and one spring running round the upper part of the verge thereof. Though this has a disadvantage which those of two springs, &c. were free from, in that a sudden jerk or confused shake will alter its vibrations, and put it in an unusual hurry.

The time of these inventions was about the year 1658, as appears, among other evidences, from an inscription on one of the double-ballance watches

presented to king Charles II. viz. Robert Hooke invent. 1658, T. Tompion fecit, 16. The invention presently got into reputation, both at home and abroad; and two of them were sent for by the dauphin of France.

Soon after this, Mr. Huygens's watch, with a spiral spring, got abroad, and made as great noise in England, as if the longitude could be found out by it. It is certain, however, that his invention was later than the year 1673, when his book *de Horol. Oscillat.* was published, wherein he has not one word of this, though he has of several other contrivances in the same way.

*Astronomical WATCH*, a machine invented by Mr. Neale, for solving several astronomical problems. It has two glasses; that in the front covers a dial-plate, as in common watches; the other on the back-side, covers a plate forming a segment of a globe, on which are drawn twenty-four meridian lines, with the names of so many countries, at 15° difference of longitude from each other. (See plate XCIII. fig. 1.) This plate makes an entire revolution in twenty-four hours; and, consequently, every country thereon passes by the sun, represented by A. Round this plate is a circle divided into twenty-four hours, also at rest; by means of which, when the moveable plate is made to correspond with the true time, shewn by the hands on the common side, the time of day or night, at the several countries specified, is shewn by the hour-circle. Round the moveable plate, and between it and the circle of hours above described, moves a narrow circle, on which is engraved the moon's age; and over 29½ is placed an ivory ball, B, representing the moon: and at right angles each way, are placed two pins, C, and D, one eastward, and the other westward; by means of which, the time of the moon's rising, southing, and setting, at those different places, is shewn in a very entertaining manner. Several other useful astronomical problems may also be solved thereby.

*Striking WATCH*, one which, besides the common watch-work for measuring time, has a clock-part for striking the hours; so that, properly speaking, they are pocket-clocks. See *CLOCK*.

*Repeating WATCH*, one that by only pulling a string, pushing in a pin, &c. repeats the hour, quarter, or minute, at any time of the day or night.

*WATCHING, or WAKEFULNESS, Insomnia*, in medicine, is produced by two great a determination of the nervous fluid, to the organs of the senses; whereby these organs are prepared to receive, readily, any impression from external objects, which they propagate to the brain, and furnish the soul with divers occasions of thinking. This extraordinary flux of spirits may have two causes; for, 1. The sensible objects may strike the organ with too much force. In which case, the animal spirits being

ing violently agitated, and those agitations continued by the nerves to the brain, they give a like motion to the brain itself; the necessary consequence of which is, that the animal must wake. Thus, a loud shriek, pains, head-ach, gripes, coughing, &c. cause waking. And the soul's being oppressed with cares, or deeply engaged in thinking, contributes to the same, since, as it acts by the ministry of the spirits, any cares or meditations that keep them in motion, must produce watchfulness. Of this kind are those inveterate wakings of melancholic persons, some of whom have been known to pass three or four weeks without a wink of sleep. See the article SLEEP.

2. The other cause is in the spirits themselves, which have some extraordinary disposition to receive motion, or to persist in it; as from their too great heat, or that of the brain, in fevers, &c. Hence it is that it is most frequent in summer, in the heat of youth.

Long fasting has the same effect; the want of food subtilizing the spirits, and drying the brain. The same is likewise an ordinary symptom in old age, by reason the pores of the brain and nerves, having been much widened by the continual passage of spirits, for a great number of years, the spirits now pass and repass through them with too much ease, and need not any extraordinary motion to keep the mind awake.

There are instances of waking forty-five nights successively; and we even read of a melancholy person, who never slept once in fourteen months. Such watchings usually degenerate into madness.

When the cause is known, it must be removed, if possible, and the irritated spirits must be appeased with emulsions, especially of poppy-seeds, or with the thebaic tincture, or theriaca, and other opiates in general, not neglecting the original diseases. In fevers, a moist softening diet is beneficial; as also preparations of barley, emulsions of poppy-seeds and almonds, decoctions of scorzonera-roots, almond cream, and winter flummery used as an aliment: likewise tea made of cowslip-flowers, and gentle laxatives. When the patient is restless and wakeful the night before a crisis, no hypnotics should be given.

When there is no other disease, the patient should shun all care, and intense thinking, especially in the evening: he should also use exercise, and eat light suppers. If it is caused by pains, they should be appeased by antispasmodics, things which temperate, and diaphoretics; and if these will not do, mild opiates must be added.

In old persons, all care and solitude must be banished; the mind should be quiet, and the moderate use of generous wine may be allowed in the evening; likewise medicines of amber and musk will be proper, and confectio alkermes, or theriaca with wine. The drinking of hot water, and principally

coffee, must be forbid after dinner. See the article FEVER.

**WATER**, *Aqua*, in physiology, a simple, fluid, and liquid body, reputed the third of the four vulgar elements. Sir Isaac Newton defines water to be a fluid salt, volatile and void of taste: but this definition Boerhaave sets aside, in as much as water is a menstruum or dissolvent of salts and saline bodies, which does not agree with the notion of its being a salt itself; for we do not know of any salt that dissolves another. This last-mentioned philosopher, therefore, defines water, a very fluid, scentless, tasteless, transparent, colourless liquor, which turns to ice with a certain degree of cold.

Though water be defined a fluid, it is a point controverted among philosophers, whether fluidity be its natural state, or the effect of violence. We sometimes find it appear in a fluid, and sometimes in a solid form; and as the former, in our warmer climate, is the more usual, we conclude it the proper one, and ascribe the other to the extraneous action of cold.

Boerhaave, however, asserts the contrary, and maintains water to be naturally of the crystalline kind; since, wherever a certain degree of fire is wanting to keep it in fusion, it readily grows into a hard glebe, under the denomination of ice. Mr. Boyle is of the same opinion. Ice, he observes, is usually said to be water brought into a preternatural state by cold; but with regard to the nature of things, and setting aside our arbitrary ideas, it might as justly be said, that water is ice preternaturally thawed by heat.

If it be urged, that ice, left to itself, will, upon the removal of the freezing agents, return to water; it may be answered, that (not to mention the snow and ice which lie all summer on the Alps, and other high mountains, even in the torrid zone) we have been assured, that in some parts of Siberia, the surface of the ground continues more months in the year frozen by the natural temperature of the climate, than thawed by the heat of the sun; and a little below the surface of the ground, the water which chances to be lodged in the cavities there, continues in a state of ice all the year round; so that when, in the heat of the summer, the fields are covered with corn, if you dig a foot or two deep, you shall find ice and a frozen soil.

Water is generally divided into salt and fresh, with regard to the ocean and rivers. But, according to Dr. Shaw, it seems divisible into as many different species, as the earth is into beds. Thus there are mineral waters of various kinds, according to the mineral substance they run over, and become impregnated with; though this impregnation sometimes happens in the way of vapour and exhalation. Water, therefore, in the general, may be as mixed a body as earth, and perhaps neither of them naturally exists in any considerable purity.

In a general analysis of water, the doctor found,  
1. That common warm water throws up numerous little bubbles, and explodes, in the exhausted receiver of the air-pump; for which reason, water contains what may, by way of distinction, be called æther or spirit.

2. It contains a merely aqueous part, distinct from æther and the sediment, as appears from distilled common water.

3. It contains a dry solid matter, which is either earthy or saline, as appears upon a full evaporation, and from the insides of tea-kettles, which, after long use, are lined with a stony matter, that beats off in flakes or crusty pieces.

Water is not only contained in the earth as in a reservoir, but likewise floats in the atmosphere. In both cases, it is actuated, rarified, and put in motion by heat, so as to prove instrumental in producing effects. Thus it produces clouds, rains, dews, springs, and rivers. It refreshes the earth, recruits vegetables, and is the support of fish and other animals by conveying nutriment to all their parts. It is also the first and immediate instrument of fermentation, putrefaction, corruption, and change in all vegetable and animal subjects.

But the nature and uses of water, will best appear from the following experiments:

1. That water is contained in many solid bodies, and to appearance in dry bodies, was proved thus: a piece of the hardest and driest bone being procured, and distilled in an earthen retort, with degrees of fire, a very large proportion of water, along with much oil and volatile salt, was obtained: whence it appears, that animal matters are resolvable into the four chemical principles, water, oil, salt, and earth. This experiment holds true even of the oldest hartshorn, the driest and hardest woods, earths, and pulverized stones.

Whence it also appears, that water may be concealed in solid bodies, and make a constituent part thereof: for it is not meant that water insinuates itself into the superficial pores of bodies, such as wood, skins, &c. so as to swell them in moist weather, and leave them shrunk in dry; but that it remains permanently intermixed as an essential ingredient, or as a part of solid bodies. See BODY.

2. That water may be collected from the driest air, or in the hottest climate, was proved by the following experiment:

Half a pint of common water was put into a cylindrical glass, wiped perfectly dry on the outside; then was added to the water, two ounces and three quarters of pulverized and dry sal ammoniac; these were stirred briskly together, whereupon the water floating in the external air, was, by the coldness thus produced, condensed on the outside of the glass as the salt dissolved within, and trickled down in small veins, into the shallow basin set underneath to receive it.

This experiment holds in all climates and places of different heights where it has been tried; whence, by the law of induction, we may make it universal, till any contradictory instance appears. Thus, therefore, it may hold in the most parched countries and hottest seasons, so as to afford an agreeable method of cooling potable liquors, and render them more refreshing. For if the containing glass of the salt and water be set in any liquor, the liquor will be cooled thereby; and if any considerable improvement could be made in the contrivance, it is observed, that it might, in some measure, serve to supply the thirsty traveller in parched deserts, and the sailors with fresh water at sea.

3. To determine the proportion of water contained in an assigned portion of the atmosphere, we are directed by the following experiment:

Having by means of the air-pump, and an exact pair of scales, found the weight of a certain quantity of air, contained in a large glass vessel, there was included therein a certain known weight of well-dried potential cautery, whose property it is powerfully to attract the moisture of the air. This vessel was kept close stopped for several hours; during which time, the potential cautery was grown wet, in which state being weighed again, it was found considerably to increase; which must be either owing to the water attracted out of the air in the glass, or to a condensation of the air itself into an aqueous fluid; for such a fluid might now by distillation be obtained from the matter thus run per deliquium.

It is observed that there is room to suspect, that if this experiment were made in perfection, a weight of water almost equal to that of the air included in the vessel, might be thus obtained, which might prove an extraordinary discovery, and shew what some have endeavoured to prove, that the matter of common air is little more than water.

4. That an earthy substance is naturally contained in water, was proved as follows. Three several glasses were filled with pure rain-water, spring-water, and Thames-water, and suffered to stand, close covered, for some days before they were exhibited. There was an earthy sediment then deposited in all the three, but most in the Thames-water, the sediment whereof was not only larger, but also more foul and muddy than in the rain-water; though here, also, it was dirty, perhaps, because not carefully collected; whereas, in the pump-water, it was white, scaly, flaky, and shining, like fine spangles of talc. This experiment is also universal, so far as it has been tried with care, and holds true of the waters of all species and all countries, particularly in those called mineral waters, from which an earthy substance may usually be precipitated by art, in a considerable proportion.

Certain experiments carefully made, and repeated, shew that the terrestrial matter naturally contained in water, has a principal share in the growth and increase

crease of vegetables; all the plants that thrive in water appearing to enlarge their bulk in proportion to the earthy matter they draw from the water. Whence pure elementary water, seems but a kind of vehicle to convey this nutrimental or substantial part, and deposite it in the vessels thro' which the water moves, in order to its general exit at the surface of vegetables. But we are not here to exclude the instrumental efficacy of the two other elements, fire and air. And this appearing to be the general office of water, in the whole animal and vegetable kingdoms, viz. the conveyance or distribution of the alimentary matter to all their parts, it may be proper to consider its physical properties, which would wonderfully fit it for this office.

The figure of its component parts appears to be smooth and spherical, like those of quicksilver; whence it becomes extremely moving and penetrating. Thus it readily enters the pores of wood, leathers, skins, chords, musical strings, &c. thus likewise it becomes capable of moving and agitating particles of matter less active than itself, and so proves the more immediate physical agent of fermentation, putrefaction, solution, &c. and thus it also conveys earthy and saline matters through our filters of paper, stone, &c. and even raises some proportion of them in distillations. Its particles likewise appear to be extremely minute, and so have a large share of surface.

Hence water is admirably fitted for a solvent, or for readily entering the pores of salts, and coming into full contact with all their particles; and thus it will pass where air cannot, on account of its moisture, or lubricating power, whereby it fastens mucilaginous matters, and will therefore soak through the close pores of a bladder.

The specific gravity of water, and consequently its goodness by its lightness, are to be directly judged of by the hydrostatical balance. This experiment is a good substitute for several other ways of examining the purity and goodness of waters, both common and mineral; for it appears by numerous instances, that light waters are, *ceteris paribus*, the best, purest, and wholesomest. That water is accounted best and wholesomest, which is not only the lightest and freest from earthy sediment, but that which is most spiritous; and these properties are usually found in pure rain-water; that being naturally distilled from the ocean and rivers, or by the heat of the sun raised up into the atmosphere, from whence it is returned much after the manner of common distillation.

From the preceding, and other experiments of Dr. Shaw, made upon water, he deduces the following axioms:

First, we have seen, That water is naturally contained in some of the driest and hardest bodies, and in the driest air. 2. That itself naturally contains an earthy substance. 3. That it is the proper men-

struums of salts, dissolving more of one, and less of another. 4. That one good sign of its purity and wholesomeness is levity. 5. That the ingredients of a mineral water may be discovered by chemical expedients: and, 6. That mineral-waters are imitable by art from such discovery.

Secondly, That water is of infinite use in all the works both of nature and art, as without it there could be no generation, nutrition, or accretion, performed in any of the animal, vegetable, mineral, marine, or atmospherical regions. The blood could not flow in the veins, the sap in the vessels of vegetables, nor the particles of minerals concrete and grow together, without water. It is this that makes the largest part of our blood, our drink, and other aliments. There could be no corruption, fermentation, or dissolution, carried on without it; no brewing, no distilling, no wines, no vinegar, no spirits, made without it.

Thirdly, That we meet with water under an infinite variety of forms, and in an infinite variety of bodies, as that of air, vapour, clouds, snow, hail, ice, sap, wines, blood, flesh, bone, horn, stone, &c. through all which it seems to pass unaltered, as an agent or instrument that suffers no alteration by re-action, but remains capable of resuming the form of water again upon occasion.

Fourthly, That water, in its own common state, appears to be a combination of all the elements together, as containing a quantity of fire, which keeps it fluid; a quantity of air, and a quantity of earth: whence it can be no wonder that water alone, as it appears to the senses, should suffice for vegetation in some cases, where little earth is wanted, or for supporting animal and mineral life, where no great degree of nutriment is required; and hence it proves a gluten, or cement, to some bodies, and a solvent to others; thus it consolidates brick, plaster of Paris, stone, bone, &c. but dissolves salts, and subtile earths approaching to salts, and becomes the instrumental cause of their action.

Fifthly, That water conveys nourishment, or a more fixed and solid matter to the parts of vegetables, where having deposited it, the finer fluid perspires into the atmosphere, which gives us the physical cause of the dampness and unwholesomeness of woody countries, as they remarkably find in America. For all large vegetables act after the manner of forcing-pumps, and continually draw in large quantities of water at their roots, and discharge it at their leaves, which intimates a method of collecting water in dry countries, and likewise of making salt-water fresh.

Sixthly, That the water in passing through plants, after having deposited its more terrestrial part, does not always go off pure, but impregnated with the finer effluvia, or more subtile particles of the vegetable; thus, making an atmosphere round every plant, according to its nature odoriferous or otherwise,

which

which supplies us with a rule for procuring the odoriferous waters of vegetables by distillation.

Seventhly, That the particles, not fine enough to go off thus along with the water, are left behind upon the surface of the leaves and flowers of plants, being now thickened or strained from their moiſter parts, and remaining in the form of honey, manna, gums, balsams, &c. according to the nature of the vegetable. And hence appears the physical cause of plants proving more odoriferous and sweet when the weather is both warm and moiſt, as immediately after a ſummer's ſhower.

Eighthly, That the chemical operator ſhould form to himſelf an hygrometer, for the ſervice of his laboratory, to determine the proportion of water at all times contained in the air, which continually mixes with his preparations, differently augments their weight, and promotes or hinders many of his operations.

Ninthly, That pure water makes the largeſt part of mineral-waters, where it is impregnated as a menſtrum, with ſeveral ingredients that it diſſolves or drinks up in its paſſage through the earth.

Tenthly, and laſtly, The preceding enquiry affords conſiderable light for diſcovering practicable ways of making ſea-water freſh and potable, and of preparing waters by art, ſo as to render them fitter for the common oeconomical uſes, and the ſervice of many particular arts, as medicine, pharmacy, cheſmtry, brewing, diſtilling, &c.

Water is of the utmoſt uſe in divers of the mechanical arts and occaſions of life, as in the motion of mills, engines, fountains, and other machines; the conſtruction of all which, ſubſervient thereto, or founded thereon, as ſiphons, pumps, &c. make the ſubject of hydraulics.

The laws, properties, &c. of this fluid, with reſpect to the fore-ſaid uſes, as its motion, gravitation, preſſion, elevation, action, momenta, and velocities, &c. which make the ſubject of hydroſtatics, may be ſeen under the articles FLUID and HYDROSTATICS.

WATER, in hydrography and geography, is a common or general name applied to all liquid tranſparent bodies, gliding or flowing on the earth; in which ſenſe, water and earth are ſaid to conſtitute our terraqueous globe.

For the periodical changes, to which the water of the ſea is liable, ſee the articles EBB, FLUX, and TIDES.

WATERS, in medicine, pharmacy, &c. called alſo artificial and medicated waters, are a kind of liquors procured or prepared by art from divers bodies, principally of the vegetable tribe, having various properties, and ſerving for various properties.

Theſe waters are either ſimple, or compound: Simple-waters are thoſe procured from ſome one vegetable body, the intention of which is to draw out the virtues of the herb, ſeed, flower, root, or the

like, ſo as it may be more conveniently given in that form than any other. The means whereby this ſeparation is effected, are either evaporation, infuſion, decoction, or diſtillation.

Compound-waters, or thoſe wherein ſeveral ingredients are uſed, are very numerous, and make a large article in commerce; ſome prepared by the apothecaries, according to the diſpenſatory preſcripts, for medicinal uſes; others by the diſtillers, to be drank by way of dram; and others by the perfumers, &c. They are diſtinguiſhed by different epithets, in reſpect either of the ſpecific virtues of the water, or the parts of the body for the cure whereof they are intended, or the diſeaſes they are good againſt, or the ingredients they are compounded of, or their different uſes, &c.

As theſe waters are exceeding numerous, and the manner of making them is not always the ſame, we muſt refer the chemical or medical reader to the diſpenſatories, wherein he will find, that every one gives his own method as the beſt one.

We have only three general remarks to add, with regard to thoſe intended for drinking, viz.

1. That ſuch wherein any thing is infuſed, as bruized fruits, pounded herbs, &c. or ground ſpices, muſt be always paſſed through a filtre, to make them finer and purer.

2. That thoſe made with brandy, or ſpirit of wine, are uſually diſtilled after mixing their ingredients, which renders thoſe liquors exceeding ſtrong and dangerous.

3. That the waters which take their names from particular things, as cinnamon, &c. have often ſome other ingredients joined with them, according to the taſte or ſmell required.

WATER, in anatomy, is applied to divers liquors or humours in the human body; ſuch is the aqua phlegmatica, which is a ſoft ſerous humour, contained in the pericardium, and wherein the heart ſwims.

*Holy-WATER*, a water prepared every Sunday, in the Romiſh church, with divers prayers, exorcifms, &c. uſed by the people to croſs themſelves withal, at their entrance to and going out of church; and pretended to have the virtue of waſhing away venial ſins, driving away devils, preſerving from thunder, diſſolving charms, ſecuring from or curing diſeaſes, &c.

Many of the reformed take the uſe of holy-water to have been borrowed from the luſtral-water of the ancient Romans. See the articles LUSTRATION, &c.

*WATER-ORDEAL*, or *Trial*, among our anceſtors, was of two kinds, by hot and by cold, water.

*Trial*, or purgation, by boiling or hot water, was a way of proving crimes, by immerging the body, or arm, in hot water, with divers religious ceremonies. In the judgment by boiling water, the accuſed, or he who perſonated the accuſed, obliged

London Bridge Water Works.

obliged to put his naked arm into a caldron full of boiling water, and to draw out a stone thence placed at a greater or less depth, according to the quality of the crime. This done, the arm was wrapped up, and the judge set his seal on the cloth, and at the end of three days they returned to view it, when if it was found without any scald, the accused was declared innocent.

The nobles, or great personages, purged themselves thus, by hot-water, and the populace by cold water.

The trial, or purgation by cold water, was thus: after certain prayers and other ceremonies, the accused was swaddled, or tied up, all in a pelatoon or lump, and thus cast into a river, lake, or vessel, of cold water, where if he sunk he was held criminal, if he floated innocent.

In the levitical law, we find mention made of water which served to prove, whether or no a woman was an adulteress; the formula, as it was performed by the priest, may be seen in the fifth chapter of the book of Numbers.

WATER, among jewellers, is properly the colour or lustre of diamonds and pearls. The term, though less properly, is sometimes used for the hue or colour of other stones.

WATER-MEASURE. Salt, sea-coal, &c. while aboard vessels in the pool or river, are measured with the corn-bushel heaped up; or else five stricked pecks are allowed to the bushel. This is called water-measure. See the article MEASURE.

WATER-MEN, are such as row in boats, or ply on the river Thames, in the government of whom the lord-mayor of London, and court of aldermen there, had always great power. They still have the appointing of their fares, the taking more than which, makes them liable to a fine of forty shillings and half a year's imprisonment. The fares assessed are, from London-bridge to Limehouse, Ratcliff-cross, &c. oars, 1s. scullers, 6d. to Wapping-dock, Rotherhithe-church-stairs, &c. oars, 6d. scullers, 3d. from either side of the water above the bridge to Lambeth and Vauxhall, oars, 1s. scullers, 6d. all the stairs between London-bridge and Westminster, oars, 6d. scullers, 3d.

Watermens boats ought to be twelve feet and a half in length, and four and a half in breadth; and no apprentice to any waterman shall take upon him the care of a boat till he is sixteen years of age, if a waterman's son; and seventeen, if a landman's son, unless he has worked with some able waterman two years, &c.

No tilt-boat, or row-berge, &c. may take in above thirty-seven passengers, or three more by the way; nor any boat above eight passengers, and two by the way, else they forfeit 5l. for the first offence, and 10l. for the second, &c. and if any person be drowned when a greater number are taken

in, the waterman is declared guilty of felony, and may be transported, &c.

WATER-SHOOT, a young sprig which springs out of the root or stock of a tree.

WATER-TABLE, in architecture, a sort of ledge left in stone, or brick-walls, about eighteen or twenty inches from the ground, from which place the thickness of the wall begins to abate.

WATER-WAY, in a ship, is a small ledge of timber, lying fore and aft on the deck, close by her sides, to keep the water from running down there.

WATER-WHEEL, an engine for raising water in great quantity out of a deep well.

WATER-WORKS, in general, denote all manner of machines moved by, or employed in raising or sustaining water; in which sense, water-mills of all kinds, sluices, aqueducts, &c. may be called water-works,

The term water-works, however, is more particularly used for such machines as are employed only in raising water.

We shall begin with the description of that at London-bridge, which is moved by the common tide-water of the river Thames. A B (plate XCIV.) the axle-tree of the water-wheel, is nineteen feet long, three feet diameter, in which C, D, E, F, are four sets of arms, eight in each place, on which are fixed G, G, G, G, four rings, or sets of fellows, in diameter twenty feet; and the floats H, H, H, fourteen feet long, and eighteen inches deep, being about twenty-six in number.

The wheel lies with its two gudgeons, or center-pins A B, upon two brasses in the pieces M N, which are two great levers, whose fulcrum, or prop, is an arched piece of timber L: the levers being made circular on their lower sides to an arch of the radius M O, and kept in their places by two arching studs fixed in the stock L, through two mortises in the lever M N. The wheel is, by these levers, made to rise and fall with the tide, which is performed in this manner: the levers M N are sixteen feet long; from M, the fulcrum of the lever, to O the gudgeon of the water-wheel, six feet; and from O to the arch at N, ten feet. To the bottom of the arch N is fixed a strong triple chain P, made after the fashion of a watch-chain, but the links arched to a circle of one foot diameter, having notches, or teeth, to take hold of the leaves of a pinion of cast iron Q, ten inches diameter, with eight teeth in it moving on an axis. The other loose end of this chain has a large weight hanging at it, to help to counterpoise the wheel, and preserve the chain from sliding on the pinion. On the same axis is fixed a cog-wheel R, six feet diameter, with forty-eight cogs. To this is applied a trundle, or pinion S, of six rounds, or teeth; and upon the same axis is fixed T, a cog-wheel of fifty-one cogs, into which the trundle V, of six rounds, works;

on.

on whose axis is a winch or windlass W, by which one man, with the two windlasses, raises or lets down the wheel, as there is occasion. And because the fulcrums of these levers MN are in the axis of the trundle K, viz. at M or X, in what situation soever the wheel is raised or let down, the cog-wheel I, I, is always equidistant from M, and works or gears truly.

By means of this machine, the strength of an ordinary man will raise about fifty ton weight.

I, I, is a cog-wheel fixed near the end of the great axis, eight feet diameter, and forty-four cogs working into a trundle K, of  $4\frac{1}{4}$  feet diameter, and twenty rounds, whose axis or spindle is of cast iron four inches in diameter, lying in brasses at each end, as at X.

ZZ is a quadruple crank of cast iron, the metal being six inches square, each of the necks being turned one foot from the center, which is fixed in brasses at each end in two head-stocks fastened down by caps. One end of this crank at Y is placed close abutting to the end of the axle-tree X, where they are at those ends six inches diameter, each having a slit in the ends, where an iron wedge is put, one half into the end X, the other half into Y, by means of which the axis X turns about the crank Z Z.

The four necks of the crank have each an iron spear, or rod, fixed at their upper ends to the respective libra, or lever, *a* 1, 2, 3, 4, within three feet of the end; these levers are twenty-four feet long, moving on centers in the frame *b b b b*; at the end of which, at *c* 1, 2, 3, 4, are jointed four rods with their forcing plugs working into *d* 1, 2, 3, 4, four cast iron cylinders four feet three quarters long, seven inches bore above, and nine below where the valves lie, fastened by screwed flanches over the four holes of a hollow trunk of cast iron, having four valves in it just over *e e e e*, at the joining on at the bottom of the barrels, or cylinders, and at one end a sucking-pipe or grate *f*, go-

ing into the water, which supplies all the four cylinders alternately.

From the lower part of the cylinders *d* 1, *d* 2, *d* 3, *d* 4, come out necks turning upward archwise, as *g g g g*, whose upper parts are cast with flanches to screw up to the trunk *h h h h*; which necks have bores of seven inches diameter, and holes in the trunk above communicating with them, at which joining are placed four valves. The trunk is cast with four bosses, or protuberances, standing out against the valves to give room for their opening and shutting; and on the upper side are four holes stopped with plugs, to take out on occasion, to cleanse the valves. One end of this trunk is stopped by a plug *i*. To the other, iron pipes are joined, as *i* 2, by flanches, through which the water is forced up to any height or place required.

Besides these four forcers, there are four more placed at the other ends of the librae, or levers (not shewn here, to avoid confusion, but to be seen on the left hand) the rods being fixed at *a* 1, 2, 3, 4, working in four cylinders, with their parts *d d*, &c. *e e*, *f*, *g g*, and *i*, as before described, standing near *k k*.

At the other end of the wheel (at B) is placed all the same sort of work as at the end A is described, viz.

The cog-wheel I.

The trundle K.

The spindle X.

The crank Y, Z.

The sucking-pipes *f*.

The four levers *a c*, *a c*, &c.

Eight forcing rods, *a d*, *a d*, &c.

Eight cylinders, *d e*, *d e*, &c.

Four trunks, such as *e e*, *h h*.

Two forcing pipes, as *i*.

So that one single wheel works 16 pumps. All which work could not be drawn in one perspective view, without making it very much confused.

*A calculation of the quantity of water raised by the engines at London-Bridge.*

In the first arch next the city is one wheel with double work of — — — 16 forcers

In the third arch { First wheel double work at one end, and single at the other — 12  
Second wheel in the middle — — — — — 8  
Third wheel — — — — — 16

In all 52 forcers

One revolution of a wheel makes in every forcer — — — — —  $2\frac{1}{2}$  strokes

So that one turn of the four wheels makes — — — — — 114 strokes

When the river is at best, the wheels go six times round in a minute, and } 6  
but  $4\frac{1}{2}$  at middle water — — — — —

The number of strokes in a minute — — — — — 684

The stroke is  $2\frac{1}{2}$  feet in a seven inch bore, raises — — — — — 3

They raise per minute — — — — — 2052 } ale gallons.

That is, 123120 gallons = 1954 hogheads per hour, and at the rate of 46896 hogheads in a day, to the height of 120 feet.

This is the utmost quantity they can raise, supposing there were no imperfections or loss at all.

But it is certain, from the considerations following, that no engine can raise so much as will answer the quantity of water the cylinder contains in the length of the forcer's, or piston's motion. For,

First, opening and shutting of the valves lose nearly so much of that column, as the height they rise and fall.

Secondly, no leather is strong enough for the piston, but there must commonly slip, or squeeze by, some water, when it is raised to a great height; and, when the column is short, it will not press the leather enough to the cylinder, or barrel: but, especially at the beginning or first moving of the

piston, there is so little weight on it, that, before the leather can expand, there is some loss.

Thirdly, and this loss is more or less, as the pistons are looser or tighter leathered.

Fourthly, when the leathers grow too soft, they are not capable of sustaining the pillar to be raised.

Fifthly, if they are leathered very tight, so as to loose no water, then a great part of the engine's force is destroyed by friction.

By some experiments accurately made on engines, whose parts are large and excellently performed, they will lose one fifth, and sometimes one fourth of the calculated quantity.

However, the perfection or errors of engines are to be compared together, by the calculated quantities of forces; for as they differ in those, they will proportionably differ in their actual performances.

## *The power by which the wheels are moved.*

The weight of the pillar of water on a forcer seven inches diameter and 120 feet high.

$7 \times 7 = 49$  lb. The pounds avoirdupoise in a yard, nearly.  
40 yards high.

1960 lb. on one forcer  
8 forcers always lifting

The whole weight 15680 lb. = 140 Cwt. = 7 ton weight on the engine at once.  
Then the crank pulls the libra 3 feet from the forcer, and 8,3 feet from the center,

$\times 11.3$

8,379.1(9,5. ton on the crank

Wallower — — — — 2,2)9,5(4,3 ton on trundle

The spur wheel — — — — 4

Radius of the great wheel — 10)17,2(1,72 tun  
20

The force on the floats 18 Cwt. 40 lb. 34,40 Cwt.

But to allow for friction and velocity, may be reckoned 1 ton  $\frac{1}{2}$

The ladles, or paddles, 14 feet long, 18 inches deep, = 22,4 square feet.

The fall of water is at a mean — — — — 2 feet.

44,8

6 gallons in a cubic foot.

268,8

10, lb. in a gallon.

112) 2688 (24 hundred.

The velocity of the water, 4 feet in 21''' of time.

21''' — 4 feet : : 50''' : = 685 feet per minute.

The velocity of the wheel = 310 feet per minute.

Quantity expended on the wheel, according to the velocity of the stream, 1433 hogheads per second.

But at the velocity of the wheel 645 hogheads per second.

The velocity of the wheel to the velocity of the water, as 1 to 2, 2.

Fig. 1. plate XCV. represents a curious machine for raising water, executed at Nynphenbourg, by the count de Whal, master of the works to the elector of Bavaria. It raises water sixty feet high into a reservoir, for the use of the elector's gardens.

The water of the canal, falling down the inclined plane at Q, turns the large wheel represented in the figure, the circumference of which, by cogs, moves the arbor D, and the same on the other side; to those are fastened the pistons of sixteen forcing pumps G, four on each side the arbor, as represented in the figure.

From each of these pumps is a tube, through which the water is forced into the pipe O, and from thence through the pipe P, which conveys it into the reservoir. These pumps are fastened together by pieces of timber, with iron clamps, to make them firm, as may be seen in the figure.

This is a very good machine, and deserves to be imitated, either in whole or in part, when water is to be raised.

**WATERING**, in the manufactures, is to give a lustre to stuffs, &c. by wetting them lightly with gum-water, and then passing them through the press, or calender, whether hot or cold.

The gum-water ought to be pure, thin, and clear, otherwise the folds of the stuff will stick together: the operation must also be performed when the water is very hot, that it may penetrate.

**WAVE**, *Unda*, in philosophy, a cavity in the surface of water, or other fluid, with an elevation aside thereof. See the article **FLUID**.

Sir Isaac Newton explains the nature of waves in water after the following manner: Let A B and C D (plate XCIII. fig. 2. N<sup>o</sup> 1.) be the surface of water quiescent in the upright leg K L, M N, of a received tube; and if the water be put into motion, and ascends in the leg K L to E F, it will descend in the leg M N to G H; so that E A = D H. Again, let P V be a pendulum vibrating in the cycloid R P S, its length V P, from the point of suspension to the center of oscillation, is equal to half the length of the water in the tube; let P be the lowest point, and P Q an arch of the cycloid, equal to the altitude A E.

The force by which the water is alternately accelerated and retarded in its motion in the tube, is the excess of the weight of water in either leg above the weight in the other; and, therefore, when the water in the leg K L ascends to E F, and in the other leg descends to G H, that force is equal to the weight of the two equal quantities of water A E F B + C G H D = 2 A E F B; and, therefore, it is to the weight of the whole water, as E A to V P, or as P Q to P R; because the semi-cycloid P R is equal to the length of the pendulum which describes it, from the nature of the curve.

All the power by which the weight P is in any

point Q accelerated or retarded in the cycloid, is, to its whole weight, as the distance P Q from the lowest point P, to the length of the semi-cycloid P R. Wherefore, as the moving forces of the water and pendulum are at first quiescent, those powers will move them equally in equal times, and cause that they go forwards and backwards together with a reciprocal motion: all which is easily deduced from what has been said of the nature of the cycloid, the motion of heavy bodies, and the forces of bodies in motion.

Hence it follows, that whether the distance A E be great or small, the reciprocations of the water will all be performed in equal times.

Also, it follows, that if the whole length of the water be 78,4 inches, each reciprocation, or ascent and descent of the water, will be performed in one second of time; because a pendulum of half that length vibrates in that time.

Lastly, if the length of the aqueous canal be increased or diminished, the time of each reciprocation will be increased or diminished in the subduplicate ratio of the length.

When the nature of waves in water is considered, it will be found to agree very nearly with the motion of the water in the tube above-mentioned; and, consequently, their motion will be similar to that of a pendulum. For let E F G (N<sup>o</sup> 2.) represent the level surface of water when it is not agitated so as to produce waves; when it is thus agitated, let A B C D represent the wavy surface, A C the highest parts of the waves, and B D the lowest or concave part. Then it is evident, the weight of the water at A above E G will cause it to descend as far below the level to B; and with the motion acquired by that descent, it will again ascend to the same height C, and so produce a constant succession of waves in the watery surface, after the same manner as was shewn in the tube.

Hence it follows, that because the length of the whole water to be moved, is from the highest point A to the lowest point B, if the length of a pendulum be half A B, it will oscillate once while the water descends from A to B; and in another oscillation, it will ascend from B to C; and so on. So that a wave will pass through its whole length in the time of two oscillations; and, therefore, in the time of one oscillation of a pendulum four times as long, or equal to A B C.

Whence, because A B C, in very large and wide waves, is nearly equal to the breadth A C; therefore, when the waves are 39,2 inches broad, they will undulate in one second of time; and, consequently, since the times of all the undulations are equal, there will be  $39,2 \div 60 = 2352$  inches, or 196 feet, run through by a wave in one minute; which is 11760 feet per hour.

Hence, also, the velocity of greater or lesser waves.

Fig. 1. Astronomical Watch.

Fig. 2. Wave.

Fig. 3. Wedge.

Fig. 4. Whispering Place.

waves will be increased or diminished in the subduplicate proportion of their breadth; that is, if  $V =$  velocity of the greater waves  $A B C D$ , and  $v =$  velocity of the lesser waves  $a. b. c. d. e. f.$  &c. then it will be  $V : v :: \sqrt{AC} : \sqrt{ac}$ . Because the velocities and times of bodies moved in any manner by gravity, are proportional to the square roots of the perpendicular altitudes, and those altitudes are as the lengths of pendulums; and, therefore, as the breadth of waves.

The waves of the sea are of two kinds, natural and accidental. The natural waves, are those which are exactly proportioned in size to the strength of the wind, whose blowing gives origin to them. The accidental waves, are those occasioned by the wind's re-acting upon itself by repercussion, from hills and mountains, or high shores, and by the washing of the waves themselves, otherwise of the natural kind, against rocks and shoals: all these cases give the waves an elevation, which they can never have in their natural state.

Mr. Boyle has proved, by numerous experiments, that the most violent wind never penetrates deeper than six feet into the water; and it should seem a natural consequence of this, that the water moved by it can only be elevated to the same height of six feet from the level of the surface in a calm: and this six feet of elevation being added to the six of excavation, in the part whence that water so elevated was raised, should give twelve feet for the utmost elevation of a wave.

This is a calculation that does great honour to its author; for count Marigli measured carefully the elevation of the waves near Provence, and found that, in a very violent tempest, they arose only to seven feet above the natural level of the sea, and this additional foot in height he easily resolved into the accidental shocks of the water against the bottom, which was, in the place he measured them in, not so deep as to be out of the way of affecting the waves; and he allows, that the addition of one-sixth of the height of a wave, from such a disturbance from the bottom, is a very moderate alteration from what would have been its height in a deep sea; and concludes, that Mr. Boyle's calculation holds perfectly right in deep seas, where the waves are purely natural, and have no accidental causes to render them larger than their just proportion.

In deep water, under the high shores of the same part of France, this author found the natural elevation of the waves to be only five feet; but he found, also, that their breaking against rocks, and other accidents, to which they were liable in this place, often raised them to eight feet high.

We are not to suppose, from this calculation, that no wave of the sea can rise more than six feet above its natural level in open and deep water; for waves immensely higher than these are formed, in violent

tempests, in the great seas. These, however, are not to be accounted waves in their natural state, but they are single waves formed of many others; for in these wide plains of water, when one wave is raised by the wind, and would elevate itself up to the exact height of six feet, and no more, the motion of the water is so great, and the succession of the waves so quick, that, during the time this is rising, it receives into it several other waves, each of which would have been at the same height with itself; these run into the first wave, one after another, as it is rising: by this means its rise is continued much longer than it naturally would have been, and it becomes terribly great. A number of these complex waves arising together, and being continued in a long succession, by the continuation of the storm, makes the waves so dangerous to ships, which the sailors, in their phrase, call mountains high.

WAVE-OFFERING, in Jewish antiquity, a sacrifice offered by agitation, or waving, towards the four cardinal points of the compass. See the article SACRIFICE.

WAVED, WAVY, or WAVEY, in heraldry, is said of a bordure, or any ordinary, or charge, in a coat of arms, having its out-lines indented, in manner of the rising and falling of waves; it is used to denote, that the first of the family in whose arms it stands, acquired its honours for sea-service.

WAVING, in the sea-language, is the making signs to a vessel to come near, or keep off.

WAVREN, or GAVEREN. See the article GAVEREN.

WAVY. See the article WAVED.

WAX, or Bees-WAX, in natural history, a firm and solid substance, moderately heavy, and of a fine yellow colour, formed by the bees from the farina of flowers, which they work up and compress into a mass, or sort of cake, and of which they form their honey-combs; from whence it is obtained by heating and straining them through a linen cloth, or by pressing them betwixt iron plates, &c.

The best sort is that of a lively yellow colour, and an agreeable smell, somewhat like that of honey: when new it is toughish, yet easy to break; but by age it becomes harder and more brittle, loses its fine colour, and in a great measure its smell. See the article HONEY COMB.

From the common yellow wax, by the mere effect of sun and air, or by what is call bleaching, is formed what we term white-wax, and some, very improperly, virgin-wax. As the greater the surface is in proportion to the quantity, the sooner and more perfectly this operation is performed. The usual way is to melt the wax in hot water; when melted, they press it through a strainer of tolerable fine linen, and pour it into round and very shallow moulds. When hardened by cooling, it is taken out and exposed to the sun and air, sprinkling it now and then with

with water, and often turning it; by this means, it soon becomes white. The best sort is of a clear and almost transparent whiteness, dry, hard, brittle, and of an agreeable smell, like that of the yellow wax, but much weaker.

The common yellow wax is of very great use, both in medicine and many of the arts and manufactures. It is sometimes given internally, as in dysenteries, and other erosions of the intestines; but its great use is in the making of ointments and plasters for external use, and the greater part of those of the shops owe their consistence to it. The white wax is also an ingredient in some of the cerates and ointments of the shops; and is used in making candles, and in many of the nicer arts and manufactures, where wax is required.

*Preparations of WAX.* The butter and oil of wax are thus prepared: Cut the wax in pieces and put them into a retort, which must be half-filled with these pieces; and the rest of the retort being filled with sand, it must be placed in a sand furnace. At first, an acid spirit arises, and afterwards a thick oil, called the butter of wax, sticks in the neck of the retort, unless it be heated by applying a live coal. This may be rectified into a thin oil, by distilling it several times, without addition, in a sand heat.

The butter is an extremely soft and anodyne unguent, highly emollient and relaxing, agreeable to the nerves, and, when rubbed on contracted limbs, proves of great benefit to them. It is an excellent liniment for the piles, and takes off the pain attending them in a very sudden and surprizing manner. It also keeps the skin soft, and is one of the best things known to keep it from cracking or chapping in the winter.

The oil of wax, has also a very singular virtue in curing contracted tendons and restoring flexibility to the parts. It cures chapped nipples in women who give suck beyond any other application, and it is as successful against chapped lips, and the cracking of the skin of the hands, only rubbing them once in three or four days with it. It is also of great use in discussing cold tumours arising on the face, and those on the fingers in winter.

*Sealing WAX* is made in the following manner: Take one pound of bees-wax: three ounces of fine turpentine; olive-oil, and rosin finely powdered, of each one ounce: when they are well melted, and the dross taken off, put in an ounce and a half of vermilion, or red-lead, finely ground, and stir them together till they are well incorporated: and when this mixture grows a little cool, roll it into sticks, or in any other form. If you would have it black, instead of vermilion, or red-lead, put in lamp-black. The soft, red, and green wax, used in large seals to some of our old law-writings, are thus made: Melt bees-wax over a gentle heat, with such a proportion of Venice turpentine as, when

cold, will give it the due consistence: this is determined by repeated trials, first putting in but little turpentine, and afterwards more and more, till by dropping a piece upon a marble to cool, it is found of the true consistence. They then colour it with red-lead, or vermilion, or with verditer, or whatever colours they please; the mixture in this state receiving any.

*Grafting-WAX*, a composition serving to bind the graft to the cleft of the stock. For the manner of making which, see the article *Methods of GRAFTING*.

*To imitate Fruit in WAX.* Take the fruit and bury it half way in clay; oil its edges, and that part of that part of the fruit which is uncovered; then nimbly throw on it tempered alabaster or plaster of Paris, to a considerable thickness. When this is grown dry and hard, it makes the half mould; the second half of which may be obtained in the same manner. The two parts of the mould being joined together, a little bees-wax melted and brought to a due heat, being poured through a hole made in a convenient part of the mould, and presently shook therein, will represent the original fruit.

*WAX-WORK*, the representation of the faces, &c. of persons living or dead; made by applying plaster of Paris in a kind of paste, and thus forming a mould containing the exact representation of the features. Into this mould melted wax is poured, and thus a kind of masks are formed; which being painted and set with glass eyes, and the figures dressed in their proper habits, they bear such a resemblance that it is difficult to distinguish between the copy and the original.

*WAXING*, in chemistry, the preparation of any matter to render it fit and disposed to liquify, or melt, which of itself it was not.

This is frequently done to enable things to penetrate into metals and other solid bodies.

*WAY*, a passage or road. See *ROAD*.

The Roman ways are divided into consular, prætorian, military, and public; and of these we have four remarkable ones in England, viz.

The first, Watling-street, or Watheling-street, leading from Dover to London, Dunstable, Toucester, Atterston, and the Severn, extending itself as far as Anglesea in Wales.

The second, called Hikenild, or Ikenild-street, stretches from Southampton over the river Isis at Newbridge; thence by Camden and Lichfield; then passes the Derwent, near Derby, and ends at Tinnmouth.

The third, called Fosse-way (because in some places it was never perfected, but lies as a large ditch) leads from Cornwall through Devonshire, by Tethbury, near Stow in the Wolds; and beside Coventry to Leicester, Newark, and so to Lincoln.

The fourth, called Erming, or Erminage-street, extends

extends from St. David's, in Wales, to Southampton.

*High WAY.* See HIGHWAY.

*Milky-WAY.* See GALAXY.

*WAY of a Ship,* is sometimes the same as her rake, or run, forward or backward: but this term is most commonly understood of her sailing. Thus when she goes a-pace, it is said that she hath a good way, or makes a fresh way. So when an account is kept how fast she sails by the log, it is called keeping an account of her way; and because most ships are apt to fall a little to leeward of their true course, they always in casting up the log-board, allow something for her leeward way.

*WAY of the Rounds,* in fortification, is a space left for the passage of the rounds between the rampart and the wall of a fortified town. This is not now much in use; because the parapet, not being above a foot thick, is soon overthrown by the enemy's cannon.

*WAY-WISER,* an instrument otherwise called perambulator. See the article PERAMBULATOR.

*WAY-WODE,* a title given to the governors of the chief places in the empire of Muscovy, as also in Poland.

*WAYFARING-TREE,* the English name for the common viburnum. See VIBURNUM.

*WEAR,* or *WEER,* a great flank or dam in a river, fitted for the taking of fish, or for conveying the stream to a mill.

New wears are not to be made, or others altered, to the nuisance of the public, under a certain penalty.

*WEASEL,* in zoology, a species of mustela, with the tip of the tail black. See the article MUSTELA.

This is a smaller animal than the pole-cat: the head is small, of an ovated form, and sharp at the snout: the ears are small, short, and patulous; the eyes of a fierce aspect; the mouth well furnished with teeth; the upper jaw longer than the under: the body is about eight inches long, and slender: the tail is a third part the length of the body; the legs are short and slender; the feet have five toes armed with sharp claws; the whole body is covered with a fine and tolerably long fur: the back is of a darkish colour, and the belly is white.

*WEATHER,* the state or disposition of the atmosphere with regard to heat, cold, wind, rain, frost, &c.

As it is in the atmosphere that all plants and animals live, and as that appears to be the great principle of most animal and vegetable productions, alterations, &c. there does not seem any thing, in all philosophy, of more immediate concernment to us than the state of the weather, and a knowledge of the great influence it has on our bodies. What vast, but regular, alterations a little turn of weather makes in a tube filled with mercury, or spirits

of wine, or in a piece of string, &c. every body knows, in the common instance of barometers, thermometers, &c. and it is owing partly to our inattention, and partly to our unequal and intemperate course of living, that we do not feel as great and regular ones in the tubes, chords, and fibres of our own bodies.

*WEATHER-COCK,* or *WEATHER-VANE,* a moveable vane in form of a cock, or other shape, placed on high, to be turned round according to the direction of the wind, and point out what quarter the wind blows from. See WIND.

*WEATHER-GLASSES,* are instruments contrived to indicate the state or disposition of the atmosphere, and the various alterations in the weather; such are barometers, thermometers, hygrometers, &c.

*WEATHER-GAGE,* in the sea-language. See GAGE.

*WEATHERING,* among sailors, signifies the doubling, or sailing by a head-land, or other place.

*WEAVING,* the art of working a web of cloth, silk, or other stuff, in a loom with a shuttle.

*WEAVING-LOOM,* a machine for weaving cloth, silk, &c. by raising the threads of the warp in order to throw in the shoot, and strike it close. Of these there are various kinds, distinguished by the different sorts of cloths, stuffs, silks, &c. in which they are employed, and which are chiefly distinguished by the number and variety of the threads they raise in order to work the warp, either plain or in figures, by making more or less of the woof or shoot appear through the warp.

In order to give a general idea of weaving, we shall here describe the parts of the common weaver's loom. See plate LXXXIX. fig. 9. in which 9, 9, are the loom-posts; 10, the cross-bars; 11, the batten, which serves to strike in, and close more or less the threads of the woof; 12, the cap of the batten, or a long bar, which the weaver takes hold of in one hand and then in the other; 13, the block, or under part of the same, containing the reed within the lower bar; 14, the cross-piece, or burdon and pin, which helps to make the batten moveable; 15, the gallows, a piece of wood suspending the pulley, on which the cord moves that is tied to the two lams; 16, the breast-bar, a flat square piece of wood, with an opening in it to let the stuff through, which is rolled on the knee-roll; 17, the cane-roll, which the warp is turned on at the other end of the loom; 18, the reed; 19, pulleys upon which the cords roll that are fastened to the lams; 20, the tumbler, which is a cord that passes from one lam to the other over the pulley 21, and causes the working of the lams by its ascending and descending; 22, the muffle, in which the pulley acts; 23, a skain, or leish, cut into proper lengths, to mend the leashes of the harness that happen to break; 24,

a bobbin of the warp, to mend the threads of the warp that occasionally break; 25, lizard-thread, to mend those of the lizier that happen to break, and which, especially in cloth, are very different from the warp; 26, the box to hold the quills; 27, the foot-bar; 28, the trundles, or moveable bars, tied with two cords to the lower virgee of each lam. When the foot presses a treadle, the lam that is fastened to it sinks, and the other rises by the help of the tumbler. 29, the foot-step; 30, the temple, a double flat ruler, having small teeth at the extremities; it may be lengthened or shortened by the help of a catch that is in one of the rulers, and introduced in a groove in the other ruler. The teeth in the extremities are fastened in the lizier of the work, by which means it is kept of an equal breadth; and as the work advances, the temple is moved forwards; 31, the shuttle, seen in front and profile; 32, the knee-roll, on which the work is rolled as it is wove; 33, the tantow, an iron lever to turn the knee-roll; 34, the reed, seen separate.

WEB, a sort of tiffue, or texture formed of threads interwoven with each other; some whereof are extended in length, and called the warp; and others drawn across, and called the woof. See the articles CLOTH, WARP, &c.

Spider's WEB, or COBWEB. See the article COBWEB.

WEDGE, *Cuneus*, one of the mechanical powers, as they are called. See POWER.

The wedge is a triangular prism, whose bases are equilateral acute-angled triangles. See the article PRISM.

The power of the wedge ACBH (pl. XCIII. fig. 3.) is evident, from its consisting of two equal inclined planes, AHC and BHC: but as it is chiefly used to separate the adhering parts of wood, the cohesion of which is every where variable and uncertain, there can be no regular calculation of the actual effect of the wedge, in this case. But if we suppose the power of cohesion in the wood ADEB to be uniform, or to make every where an equal resistance to the wedge ABC, dividing its parts AF and BG; then the power of the wedge would be to the resistance of the wood, as their velocities inversely, that is, as the spaces moved through in the same time, that is, as the height of the wedge HC to half its width AH.

WEDNESDAY, the fourth day of the week, so called from a Saxon idol named Woden, supposed to be Mars, worshipped on this day.

Ash-WEDNESDAY, the first day of Lent, so called from the custom observed in the ancient Christian church, of penitents expressing their humiliation at this time, by appearing in sack-cloth and ashes. The want of this discipline is at present supplied by reading publicly on Ash-Wednesday the curses denounced in scripture against the several sorts of sins, the people repeating after each curse, Amen.

WEED, a common name for all rank and wild herbs, that grow of themselves, to the detriment of other useful herbs they grow among.

WEED, in the miners language, denotes the degeneracy of a load or vein of fine metal into an useless marcasite.

WEEK, *Septimana, hebdomada*, in chronology, a division of time comprising seven days.

The origin of this division of weeks, or of computing time by sevenths, is greatly controverted. Some will have it to take its rise from the four quarters or intervals of the moon, between her changes or phases, which, being about seven days distance, gave occasion to the division.

Be this as it will, the division is certainly very ancient. The Syrians, Egyptians, and most of the oriental nations, appear to have used it from all antiquity: though it did not get footing in the West till Christianity brought it in: the Romans reckoned their days not by sevenths but by ninths, and the ancient Greeks by decads or tenths.

Indeed, the Jews divided their time by weeks, but it was upon a different principle from the eastern nations. God himself appointing them to work six days, and to rest the sabbath, in order to keep up the sense and remembrance of the creation; which being effected in six days, he rested the seventh.

Passion-WEEK, or the Holy WEEK, is the last week in Lent, wherein the church celebrates the mystery of our Saviour's death and passion.

WEIGH, WAY, or WEY, *Waga*, a weigh of cheese, wool, &c. containing 256 pounds avoirdupoise. Of corn, the weigh contains forty bushels; of barley or malt, six quarters. In some places, as Essex, the weigh of cheese is 300 pounds.

WEIGHER, an officer in divers cities appointed to weigh the commodities bought or sold in a public balance.

WEIGHING, the act of examining a body in the balance to find its weight.

WEIGHING-CHAIR, a machine contrived by Sanctorius, to determine the quantity of food taken at a meal, and to warn the feeder when he had his quantum.

WEIGHING Anchor, is the drawing it out of the ground it had been cast into, in order to set sail, or quit a port, road, or the like.

WEIGHT, gravity, *Pondus*, in physics, a quality in natural bodies whereby they tend downwards, towards the center of the earth.

Or, Weight may be defined, in a less limited manner, to be a power inherent in all bodies whereby they tend to some common point, called the center of gravity; and that with a greater or less velocity, as they are more or less dense, or as the medium they pass through is more or less rare.

In the common use of language, weight and gravity are considered as one and the same thing. Some authors, however, make a difference between them; and

and hold gravity only to express a nifus, or endeavour to descend, but weight an actual descent. But there is room for a better distinction. In effect, one may conceive gravity to be the quality as inherent in the body; and weight the same quality, exerting itself either against an obstacle, or otherwise. Hence, weight may be distinguished, like gravity, into absolute and specific. See GRAVITY.

Sir Isaac Newton demonstrates, that the weights of all bodies, at equal distances from the center of the earth, are proportionable to the quantities of matter each contains. Whence it follows, that the weights of bodies have not any dependence on their forms, or textures; and that all spaces are not equally full of matter. Hence, also, it follows, that the weight of the same body is different, on the surface of different parts of the earth; by reason its figure is not a sphere, but a spheroid. See EARTH.

WEIGHT, *Pondus*, in mechanics, is any thing to be raised, sustained, or moved by a machine, or any thing that in any manner resists the motion to be produced.

2. Grecian and Roman weights, reduced to English troy-weight, will stand as in the following table.

|        |         |        |            |                |                |                |        |       |       | oz. dwt. gr. |    |                  |
|--------|---------|--------|------------|----------------|----------------|----------------|--------|-------|-------|--------------|----|------------------|
| Lentes |         |        |            |                |                |                |        |       |       | 00           | 00 | $\frac{8}{11}$   |
| 4      | Siliquæ |        |            |                |                |                |        |       |       | 00           | 00 | $03\frac{1}{2}$  |
| 12     | 3       | Obolus |            |                |                |                |        |       |       | 00           | 00 | $09\frac{3}{8}$  |
| 24     | 6       | 2      | Scriptulum |                |                |                |        |       |       | 00           | 00 | $18\frac{3}{4}$  |
| 72     | 18      | 6      | 3          | Drachma        |                |                |        |       |       | 00           | 00 | $06\frac{9}{16}$ |
| 96     | 24      | 8      | 4          | $1\frac{1}{2}$ | Sextula        |                |        |       |       | 00           | 03 | $00\frac{5}{8}$  |
| 144    | 36      | 12     | 6          | 2              | $1\frac{1}{2}$ | Sicilicus      |        |       |       | 00           | 04 | $13\frac{7}{8}$  |
| 192    | 48      | 16     | 8          | $2\frac{1}{2}$ | 2              | $1\frac{1}{2}$ | Duella |       |       | 00           | 06 | $01\frac{5}{8}$  |
| 576    | 144     | 48     | 12         | 18             | 16             | 4              | 3      | Uncia |       | 00           | 18 | $05\frac{1}{4}$  |
| 6912   | 1728    | 576    | 288        | 96             | 72             | 48             | 36     | 12    | Libra | 10           | 18 | $13\frac{5}{8}$  |

The Roman ounce is the English avoirdupois ounce, which they divided into several denarii, as well as eight drachms; and since they reckoned their denarius equal to the Attic drachm, this will make the Attic weights one-eighth heavier than the corresponding Roman weights. See AVOIRDUPOIS and TROY.

Modern European WEIGHTS. 1. English weights: By the twenty-seventh chapter of Magna Charta, the weights all over England are to be the same; but for different commodities, there are two different sorts, viz. avoirdupois-weight and troy-weight. The origin from which they are both raised, is a grain of wheat, gathered in the middle of the ear.

In troy-weight, twenty-four of these grains make one penny-weight sterling; twenty penny-weights make one ounce; and twelve ounces one pound.

By this weight we weigh gold, silver, jewels, grains, and liquors. The apothecaries also use the troy pound, ounce, and grain; but they differ from

WEIGHT, in commerce, denotes a body of a known weight, appointed to be put in the balance against other bodies, whose weight is required.

The security of commerce depending, in great measure, on the justness of weights, which are usually of lead, iron, or brass, most nations have taken care to prevent the falsification thereof, by stamping or marking them by proper officers, after being adjusted by some original standard. Thus, in England, the standard of weights is kept in the Exchequer, by a particular officer called the clerk of the market. See the article CLERK.

Weights may be distinguished into ancient and modern, foreign and domestic.

Ancient WEIGHTS, 1. Those of the ancient Jews, reduced to the English troy weights, will stand as in the following table:

|        |       |        | lb. oz. dwt. gr. |    |                  |
|--------|-------|--------|------------------|----|------------------|
| Shekel | —     | —      | 00               | 00 | $09\frac{02}{3}$ |
| 60     | Maneh | —      | 02               | 03 | $06\frac{10}{3}$ |
| 3000   | 50    | Talent | 113              | 10 | $01\frac{10}{3}$ |

the rest in the intermediate divisions. They divide the ounce into eight drachms; the drachm into three scruples, and the scruple into twenty grains.

In avoirdupois-weight, the pound contains sixteen ounces; but the ounce is less, by near one-twelfth, than the troy ounce; this latter containing 490 grains, and the former only 448. The ounce contains 16 drachms. 80 ounces avoirdupois are only equal to 73 ounces troy; and 17 pounds troy equal to 14 pounds avoirdupois.

By avoirdupois-weight are weighed mercury and grocery wares, base metals, wool, tallow, hemp, drugs, bread, &c.

Table of TROY-WEIGHT, as used by the Goldsmiths:

| Grains |              |          |
|--------|--------------|----------|
| 24     | Penny-weight |          |
| 480    | 20           | Ounce    |
| 5760   | 240          | 12 Pound |

Table of Troy-WEIGHT, as used by the Apothecaries:

| Grains |         |        |           |
|--------|---------|--------|-----------|
| 20     | Scruple |        |           |
| 60     | 3       | Drachm |           |
| 480    | 24      | 8      | Ounce     |
| 5760   | 288     | 96     | 12 Pound. |

Table of Avoirdupois-WEIGHT.

|          |        |      |       |      |       |      |                     |  |
|----------|--------|------|-------|------|-------|------|---------------------|--|
| Scruples | Drachm |      | Ounce |      | Pound |      | Quintal, or Hundred |  |
| 3        | 8      | 16   | 112   | 2240 | 20    | Ton. |                     |  |
| 24       | 128    | 1792 |       |      |       |      |                     |  |
| 384      |        |      |       |      |       |      |                     |  |
| 43008    |        |      |       |      |       |      |                     |  |
| 860100   |        |      |       |      |       |      |                     |  |

The moneyers, jewellers, &c. have a particular class of weights, for gold and precious stones, viz. carat and grain; and for silver, the penny-weight and grain. See the article CARACT.

The moneyers have also a peculiar subdivision of the grain troy, viz.

|     |   |       |   |      |   |            |
|-----|---|-------|---|------|---|------------|
| The | { | Grain | } | into | { | 20 Mites,  |
|     |   | Mite  |   |      |   | 24 Droits, |
|     |   | Droit |   |      |   | 20 Perits, |
|     |   | Perit |   |      |   | 24 Blanks. |

The dealers in wool have likewise a particular set of weights, viz. the sack, weigh, tod, stone, and clove.

2. French weights: The common or Paris pound is 16 ounces; which they divide two ways: the first division is into two marcs; the marc into 8 ounces; the ounce into 8 gros; the gros into 3 penny-weights; the penny-weight into 24 grains; the grain equal to a grain of wheat. The second division of the pound is into 2 half pounds; the half pound into 2 quarters; the quarter into 2 half quarters; the half quarter into 2 ounces; and the ounce into 2 half ounces.

The weights of the first division are used to weigh gold, silver, and the richer commodities; and the weights of the second division, for commodities of less value.

| Grains |              |      |           |
|--------|--------------|------|-----------|
| 24     | Penny-weight |      |           |
| 72     | 3            | Gros |           |
| 576    | 24           | 8    | Ounce     |
| 4608   | 192          | 64   | 8 Marc    |
| 9216   | 384          | 128  | 16 Pound. |

| Half ounce |      | Ounce              |                      |
|------------|------|--------------------|----------------------|
| 4          | 2    | Half-quarter pound |                      |
| 8          | 4    | 2                  | Quarter pound        |
| 16         | 8    | 4                  | Half pound           |
| 32         | 16   | 8                  | 4 2 Pound            |
| 3200       | 1600 | 800                | 400 200 100 Quintal. |

But the pound is not the same throughout France. At Lyons, the city pound is only 14 ounces; so that 100 Lyons pounds make only 88 Paris pounds. But beside the city pound, they have another at Lyons for silk, containing 16 ounces. At Tholouse, and throughout the Upper-Languedoc, the pound is 13 ounces and a half of Paris weight. At Rouen, beside the common Paris pound and marc, they have the weight of the vicomte; which is 16 ounces, a half, and five-sixths of the Paris weight.

The weights, enumerated under the two articles of English and French weights, are the same that are used throughout the greatest part of Europe; only under somewhat different names, divisions, and proportions.

Particular nations have also certain weights peculiar to themselves: thus Spain has its arrobas, containing 25 Spanish pounds, or one-fourth of the common quintal: its quintal macho, containing 150 pounds, or one-half common quintal, or 6 arrobas: its adarme, containing one-sixteenth of its ounce. And for gold, it has its castellan, or one-hundredth of a pound: its tomin, containing 12 grains, or one-eighth of a castellan. The same are in use in the Spanish West-Indies.

Portugal has its arroba, containing 32 Lisbon aratels, or pounds. Savary also mentions its faratelle, containing 2 Lisbon pounds; and its rottoli, containing about 12 pounds. And for gold, its chego, containing four carats. The same are used in the Portuguese East-Indies.

Italy, and particularly Venice, have their migliaro, containing four mirres; the mirre, containing 30 Venice pounds: the saggio, containing a sixth part of an ounce.

Genoa has five kinds of weights, viz. large weights, whereby all merchandizes are weighed at the custom-house: cash-weights for piastrs, and other species: the cantara, or quintal, for the coarsest commodities: the large balance for raw silks; and the small balance for the finer commodities. Sicily has its rotollo, 32 and a half pounds of Messina.

Germany, Flanders, Holland, the Hanse-Towns, Sweden, Denmark, Poland, &c. have their schippondt, which at Antwerp and Hamburgh, is 300 pounds;

pounds; at Lubeck, 320; and at Coningsberg, 400 pounds. In Sweden, the schippont for copper is 320 pounds; and the schippont for provisions 400 pounds. At Riga and Revel, the schippont is 400 pounds; at Dantzic, 340 pounds; in Norway, 300 pounds; at Amsterdam, 300; containing 20 lyfpondts, each weighing 15 pounds.

In Muscovy, they weigh their large commodities by the bercherockt, or berkewits, containing 400 of their pounds. They have also the poet, or poede, containing 40 pounds, or one-tenth of the bercherockt.

In order to shew the proportion of the several weights used throughout Europe, we shall add a reduction of them to one standard, viz. the London and Amsterdam pound.

1. Proportion of the weights of the principal places of Europe:

The 100 lb. of England, Scotland, and Ireland, are equal to

| lb. | oz.           |                                  |
|-----|---------------|----------------------------------|
| 91  | 8             | of Amsterdam, Paris, &c.         |
| 96  | 8             | of Antwerp or Brabant            |
| 88  | 0             | of Rouen, the viscounty weight   |
| 106 | 0             | of Lyons, the city weight        |
| 90  | 9             | of Rochelle                      |
| 107 | 11            | of Toulouse, and Upper-Languedoc |
| 113 | 0             | of Marseilles or Provence        |
| 81  | 7             | of Geneva                        |
| 93  | 5             | of Hamburgh                      |
| 89  | 7             | of Francfort, &c.                |
| 96  | 1             | of Leipzig, &c.                  |
| 137 | 4             | of Genoa                         |
| 132 | 11            | of Leghorn                       |
| 153 | 11            | of Milan                         |
| 152 | 0             | of Venice                        |
| 154 | 10            | of Naples                        |
| 97  | 0             | of Seville, Cadiz, &c.           |
| 104 | 13            | of Portugal                      |
| 96  | 5             | of Leige                         |
| 112 | $\frac{2}{3}$ | of Russia                        |
| 107 | $\frac{1}{2}$ | of Sweden                        |
| 89  | $\frac{1}{2}$ | of Denmark.                      |

2. Proportion of the weights of the chief cities in Europe, to those of Amsterdam. An 100 pounds of Amsterdam are equal to

| lb.              |                           |
|------------------|---------------------------|
| 108              | of Alicant                |
| 105              | of Antwerp                |
| 120              | of Archangel, or 3 poedes |
| 105              | of Arschot                |
| 120              | of Avignon                |
| 98               | of Basil in Switzerland   |
| 100              | of Bayonne in France      |
| 166              | of Bergamo                |
| 97               | of Bergen-op-zom          |
| 95 $\frac{1}{4}$ | of Bergen in Norway       |
| 111              | of Bern                   |
| 100              | of Basançon               |

|                   |                               |
|-------------------|-------------------------------|
| 100               | of Bilboa                     |
| 105               | of Bois le duc                |
| 151               | of Bologna                    |

| 106               | of Seville                    |
| 114               | of Smyrna                     |
| 110               | of Stetin                     |

81 of Tholouse and Upper-Languedoc  
 125 of Turin  
 158½ of Valencia  
 182 of Venice, small weight.

**WEIGHTS, used in the several parts of Asia, the East-Indies, China, Persia, &c.**—In Turkey, at Smyrna, &c. they use the batman, or battemant, containing 6 occos; theocco weighing 3 pounds four fifths English. They have another batman much less, consisting, as the former of 6 occos; but theocco only containing 15 English ounces: 44 occos of the first kind make the Turkish quintal.

At Cairo, Alexandretta, Aleppo, and Alexandria, they use the rotto, roton, or rottoli. The rottoli at Cairo, and other parts of Egypt, is 144 drachms; being somewhat over an English pound. At Aleppo there are three sorts of rottos; the first, 720 drachms; making about 7 English pounds, and serving to weigh cotton, galls, and other large commodities; the second, is 624 drachms, used for all silks but white ones, which are weighed by the third rotto of 700 drachms. At Seyda the rotto is 600 drachms.

The other ports of the Levant, not named here, use some of these weights; particularly theocco, or ocqua, the rottoli, and rotto.

The Chinese weights are, the piece, for large commodities; it is divided into 100 catis, or cattis; though some say, into 125; the cati into 16 taels, or tales; each tael equal to  $1\frac{1}{4}$  of an English ounce, or the weight of 1 rial and  $\frac{1}{12}$ , and containing 12 mas, or masses, and each mas 10 condrens. So that the Chinese piece amounts to 137 English pounds avoirdupois, and the cati to 1 pound 8 ounces. The picol for silk, containing 66 catis and  $\frac{3}{4}$ ; the bahar, bakaire, or barr, containing three hundred catis.

Tonquin has also the same weights, measures, &c. as China. Japan has only one weight, viz. the cati; which, however, is different from that of China, as containing twenty taels.

At Surat, Agra, and throughout the states of the great mogul, they use the man, or maund, whereof they have two kinds; the king's man, or king's weight; and the man simply; the first used for the weighing of common provisions, containing forty seers, or serres; and each seer a just Paris pound. The common man used in the weighing of merchandize, consists likewise of 40 seers, but each seer is only estimated at 12 Paris ounces, or  $\frac{1}{4}$  of the other seer.

The man may be looked upon as the common weight of the East-Indies, though under some difference of name, or rather of pronunciation; it being called mao at Gambaya, and in other places mein, and maun. The seer is properly the Indian pound, and of universal use; the like may be said of bahar, tael, and cattis, above-mentioned.

The weights of Siam, are, the piece, containing 2 shans, or cattis; but the Siamese cattis is only half the Japonese; the latter containing 20 taels, and the former only 10: though some make the Chinese cattis only 16 taels, and the Siamese 8. The tael contains four baats or ticals; each about a Paris ounce; the baat 4 selings, or mayonnes; the mayon 2 fouangs; the fouang 4 payes; the paye 2 clams; the sompaye  $\frac{1}{2}$  a fouang.

It is to be observed, that those are the names of their coins as well as weights; silver and gold being commodities there sold, as other things, by their weights.

In the Isle of Java, and particularly at Bantam, they use the gantan, which amounts to near three Dutch pounds.

In Golconda, at Visapour, and Goa, they have the furatelle, containing 1 pound 14 ounces English; the mangalis, or mangelin, for weighing diamonds and precious stones; weighing at Goa 5 grains, at Golconda, &c.  $5\frac{1}{2}$  grains. They have also the rotolo, containing  $14\frac{1}{4}$  ounces English; the meticol, containing the sixth part of an ounce; the wall, for piasters and ducats, containing the seventy-third part of a rial.

In Persia, they use two kinds of batmans, or mans; the one called cahi, or cheray, which is the king's weight; and the other, batman of Tauris. The first 13 pounds 10 ounces English; the second,  $6\frac{1}{2}$  pounds. Its divisions are, the ratel, or a 16th; the derhem, or drachm, which is the 50th; the meschal, which is half the derhem; the dung, which is the 6th part of the meschal, being equal to six carat grains; and, lastly, the grain, which is the fourth part of the dung. They have also the vakie, which exceeds our ounce a little; the sab-cheray, equal to the 1170th part of the derhem; and the toman, used to weigh our large payments of money, without telling; its weight is that of fifty abassis.

**African and American weights.** We have little to say as to the weights of America; the several European colonies there making use of the weights of the states or kingdoms they belong to. For, as to the aroue of Peru, which weighs 27 pounds, it is evidently no other than the Spanish arroba, with a little difference in the name.

As to the weights of Africa, there are few places that have any, except Egypt, and the countries bordering on the Mediterranean; whose weights have been already enumerated among those of the ports of the Levant. The Island of Madagascar, indeed, has weights, but none that exceed the drachm, nor are they used for any thing but for gold and silver.

**WEIGHT of the Air.** See AIR.  
**WEINMANNIA**, in botany, a genus of plants, whose flower consists of four equal petals larger than the cup; the stamina are eight erect and short filaments, topped with roundish antheræ; the fruit is

an ovate birostrate capsule, having two cells containing eight roundish seeds.

**WELD**, or dyers-weed, *luteola*, in botany, a plant whose root is single, white, and woody, with a few fibres; the leaves are oblong, narrow, smooth and entire; among these rise stalks to the height of three feet; these are round, hard, smooth, greenish, branched, and furnished with leaves that are less than those below. The flowers are produced on the tops of the stalks; they are of a beautiful yellowish green colour, and of the same form as those of the *reseda*, of which it is now held a species. See **RESEDA**.

It is very common in England, and grows upon dry banks, and on the tops of walls and buildings.

The seeds of weld should be sown in August, soon after they are ripe; they will come up the first moist weather, and will grow very strong the same autumn, provided they are sown by themselves. When they are pretty strong, they should be hoed out, as is practised with turneps, to destroy the weeds, and to thin them where too thick. The seed must not be too ripe when gathered, for then it will fall out; nor yet must the stalk be unripe, for then it will be good for nothing. It must be bound in handfuls, and set to dry like flax, taking care not to shake out the seeds, which are usually sold at ten shillings a bushel; and a gallon will sow an acre.

It is of great use among the dyers, for dying bright yellow and lemon colours; a great quantity of it is sown in some parts of Kent; and they cultivate it in Languedoc and Normandy in France, where they boil it in water, with allum, and then it will colour white wool yellow, and blue stuffs green.

In medicine, it is said to be opening, and to be good against the jaundice and cachexy, but is seldom used here.

**WELDING-HEAT**, in smithery, a degree of heat given to iron, &c. sufficient only for bending, or doubling it up.

**WELL**, a hole under ground, usually of a cylindrical form, walled with stone and mortar: its use is to collect the water of the strata around it.

**WELL**, in the military art, a depth which the miner sinks under ground, with branches or galleries running out from it; either to prepare a mine, or to discover and disappoint the enemy's mine.

**WELL-HOLE**, in building, is the hole left in a floor for the stairs to come up through. See the article **STAIRS**.

**WEN**, a tumor or excrescence that arises on different parts of the body, and contains a cystus, or bag filled with some peculiar matter, of which physicians reckon three kinds, viz. when this matter is soft, resembling pulp, the wen is called *atheroma*; if like honey, *meliceris*; and if like suit, *steatoma*. See the article **TUMOUR**.

**WERE**, in our old law-books, denotes a sum paid for killing a person, when such crimes were punished with pecuniary mulct, and not death.

**WERELADA**, among our Saxon ancestors, the denying an homicide on oath, in order to be quit of the fine called **WERE**.

**WERGILD**, or **WEREGELD**, in our ancient customs, the price of a man's head; a part of which was paid to the king, for the loss of his subject, a part to the lord whose vassal he was, and a part to the nearest relation of the person slain.

**WEST**, in cosmography, one of the cardinal points of the horizon, diametrically opposite to the east; and strictly defined, the intersection of the prime vertical with the horizon, on that side the sun sets in. See **HORIZON**.

In astronomy, west is chiefly used for the place in, or towards which, the sun or stars sink under the horizon. Thus we say, the sun, mars, &c. are in the west. The point the sun sets in, when in the equator, is particularly called, the equinoctial west, or point of true west. See the article **EQUINOCTIAL**.

In geography, west and western, are applied to several countries, &c. situate towards the point of sun-setting, with respect to certain others. Thus the Roman empire was anciently, and the German empire is at present, called the empire of the west, or the western empire, in opposition to that of Constantinople, which is called the eastern empire.

The Roman church is called the western church, in opposition to the Greek church. The Italians, French, Spaniards, &c. are called western nations, in respect to the Asiatics; and part of America, the West-Indies, in respect to the East-Indies.

**WHALE**, *Balæna*, in ichthyology. See the article **BALÆNA**.

The *balæna*, with the fistula in the middle of the head, and the back ridged toward the tail, is the fish determinately and properly called the whale, though the physeter (as well that with the upper jaw longest, and with a long spine on the back, as that with the back-fin very tall, and the summit of the teeth plane) is the former, called the crooked-toothed whale, and the latter, the plane-toothed whale; as is also that physeter which is a species of the *balæna*. See **PHYSETER**.

The *balæna*, or the whale properly so called, grows to a monstrous size; the head is extremely large, and of an irregular figure, the lower jaw is much larger than the upper, and covers it at the sides; the upper, is narrow and oblong, the fistula is double, or has two distinct apertures, and is situated in the middle of the head, between the eyes; the eyes are very small in proportion to the enormous bulk of the head, and are placed a great distance from one another; the whole head is somewhat depressed, and has several irregularities on its surface; the body is very thick, and somewhat rounded;

rounded; but towards the extremity of the back, there is a subacute angle, extending itself longitudinally to the tail; the tail is somewhat forked, very large, and in its horizontal situation makes a very singular figure. This is an inhabitant of the northern seas, the principal object of the Greenland fishery, and the first known species.

**WHALE-BONE**, or as it is otherwise called, whale-fins, in commerce, a commodity procured from the whale; used as stiffening in stays, fans, bulks, screens, &c. What we call whale-bone, or fins, is a horny lamina in the upper-jaw of the balæna, which supply the place of teeth, but there are none such in the lower-jaw. These laminae are commonly called whiskers, which, split and fashioned, are the whale-bone. The pizzle, or genital member of the animal, serves likewise for the same purpose.

**WHARF**, a space on the banks of a haven, creek, or hithe, provided for the convenient loading and unloading vessels upon.

The fee paid for the landing of goods on a wharf, or for shipping them off, is called wharfage, and the person who has the direction and oversight of the wharf, receives wharfage, &c. is called the wharfinger.

**WHEAT**, *Triticum*, in botany, a genus of plants, the corolla of which consists of two valves, nearly equal in size, and of the bigness of those which form the cup; the exterior valve is bellied, with an obtuse end terminated by a point, and the inner valve is plane; the stamina are three capillary filaments, topped with oblong bifurcate antheræ; the pistillum consists of a turbinated germen, supporting two hairy reflexed styles, each crowned with a plumose stigma; there is no pericarpium, the corolla inclosing the seed, which is single, of an ovato-oblong form, blunt at the ends, convex on one side, and furrowed on the other.

There are several kinds of wheat; as the white or red wheat without awns; the red-eared, the bearded wheat, the cone wheat, grey wheat, or ducks-bill wheat, Poland wheat, many-eared wheat, summer wheat, long-grained wheat, white-eared wheat, naked barley-wheat, with some other sorts. The season for sowing wheat is in autumn, and the earlier the better, if the weather is moist, as less seed is required to an acre than when it is sown late, because less of it will die; and poor land should always be allowed more seed than rich, because a greater number of the plants will perish on such land than on the other. Another thing to be considered in order to find the proper quantity of seed, is, that some kinds of wheat has its grains twice as large as others; in this case, a bushel containing but half the number of grains that it does in the small-grained wheat, one bushel of the small-grained will plant just as much as two bushels of this; therefore

the size of the seeds ought to be regarded as well as the measure.

It might be supposed, that a large grained wheat will produce larger and finer plants than the small-grained sort, but experiments have proved that there is nothing in this, for the smallest grained wheat produces fully as large plants as the other. The usual allowance of seed-wheat to one acre of land, is three bushels; but, from repeated trials, it has been found that half that quantity is sufficient; therefore if the farmers have regard to their own interest, they should save this expence of seed, which amounts to a considerable article in large farms, especially when it is to be purchased, which most of the skilful farmers do at least every other year, by way of change; for they find that the seeds continued long upon the same land, will not succeed so well, as when they procure a change of seeds from a distant country; and in the choice of the seed, particular regard should be had to the land on which it grew, for if it is light land, the wheat which grew upon strong land is the best, and *vice versa*.

There are four ways of augmenting the crops of wheat, not only in the number of the plants, but in the stalks, ears, and grains. the first is by increasing the number of stalks, from one, two, or three, to thirty or forty in each plant, in ordinary field land; and the crop is augmented by bringing up all these stalks into one ear, which is the second way; for if it be diligently observed, it will be found, that not one half of the stalks of wheat sown in the common way, never come to ear at all: nay, if a square yard of sown wheat be marked out, and the stalks thereon numbered in the spring, it will be found that no less than nine parts in ten of them are wanting at harvest time.

An experiment of the advantage of this augmentation was made by Mr. Tull in rows of wheat where the land was equally poor; one of these rows was increased so much, as to produce more grains than ten of the other, by bringing up more of its stalks into ears, and also by augmenting the ears to a much greater bigness, which is the third way; for it is very certain that the ears will be much larger or much smaller, according to the quantity of nourishment given them.

The fourth and last way of increasing the crops of wheat, is by causing the grain to be much larger in the ears. This can no way be so effectually done as by late hoeing, especially if it be done just after the wheat is gone out of blossom; by this means the grains will weigh twice as much as those produced in the same sort of wheat when this late hoeing has been omitted; their number is the same in the ear, and as the wheat is sold not by tale but by measure, the farmer's gain is double in this case, the wheat measuring twice as much as it would otherwise have done.

Thus

Thus by increasing the number of the stalks, bringing more of them up into the ear, making the ears larger, and the grains larger, plumper, and fuller in every ear, the method of horse-hoeing, by which alone this can be effected, makes a larger crop out of the tenth part of the number of plants than in the common way.

But all these advantages will be lost by those, who, though they give into the horse-hoeing way, yet will not allow breadth enough between the rows; for it is owing to their having a large space of ground alone, that as much nourishment may be given to the wheat as the farmer pleases.

Poor light land must be extremely well manured, in order to the maintaining wheat a year (which is the usual time that it is on it) if the wheat is sown in the common broad-cast way; and if it be sown late, the greater part of it perishes, not being able to survive the winter while so poor and on such land: and if it be sown in the same manner very early on strong rich land, many of the plants are destroyed. But the new method of horse-hoeing gives both to strong and to light land all the advantages necessary, and takes off all the disadvantages of both; by this method the strong land may be planted with wheat as early as the light, if plowed dry; and the hoe-plough, if rightly applied, will be able to give it nourishment almost equal to that of dung in both sorts of land.

The use of wheat is universal, it making better bread than any other corn, being more glutinous and nutritious.

However, in the eastern countries they generally prefer rice thereto, for which reason it is not so much cultivated there, especially among the original inhabitants; not but it will grow well; for it has been justly observed, by the ancients as well as moderns, that wheat will grow in almost any part of the world; and that as it is the plant most necessary to mankind, so it is the most general and the most fruitful. It grows well not only in the temperate climates, but in the very hot and very cold ones; and when in places where it never grew spontaneously, succeeds as well as where it has been always common. But where it was originally a native it is not easy to determine, though it is generally supposed that some part of Africa is the country, because in the earliest accounts we have of it, there is mention of its being transported from thence to other countries; and Sicily was the first country in Europe where this grain was cultivated.

The price of wheat in this country varies continually, and this variation is often very great in the space of one or two years; so that from being so cheap as that the farmers could not pay their rents, in the compass of a year or two the price has been doubled; for one or two plentiful harvests have lowered the price of wheat so much, as to make it

difficult for the needy farmer to go on with his business, who wants ready money for his crops as soon as he can prepare them for market. This has established a set of people called *Dealers in corn*, who have taken the advantage of the farmer's necessity, and engrossed their corn to keep it for better markets; and these dealers have of late years increased so greatly in their numbers, to the great prejudice of the raisers and consumers of corn, as may in time prove of the worst consequence, by monopolizing the greatest part of the produce, and then set their own price upon it; so that between corn-factors, as they are called, and the distillers, together with the monopolizers of farms, the price of bread may be too great for the labouring poor; which is a consideration that requires more public attention than it has hitherto met with.

Though wheat is of such very great use as an aliment, it is but little used in medicine, except as a cataplasm; which is made with the crumb of bread soaked in milk, with the yolks of eggs and saffron; this is good to ease painful swellings, and to abate inflammations. Some put the grains of wheat between two hot plates of iron, and express a sort of oil, which is affirmed to be excellent against ringworms, and for healing chaps in the skin. For the manner of grinding, &c. wheat, see the articles GRINDING, MILL, FLOUR, &c.

*Buck-WHEAT.* See the article *BUCK-Wheat*.

*Indian-WHEAT.* See *ZEA*.

*White-Cone WHEAT*, a term used by our husbandmen to express a peculiar kind of wheat, which is very strong, and has a large ear.

It is the best kind for sowing in fields subject to the blight; for the stalks of it being, for the most part, solid or full of pith like a rush, not hollow like those of common wheat; the insects that cause the blight seizing on the stalks of other wheat, does this no injury, even though they should attack it; the stalks of this kind being often found full of black specks, which are always the marks of the insect having been there, and yet the ear full, and the grain good.

This wheat makes very good bread, if the miller does not grind it too small, or the baker make his dough too hard; it requiring to be somewhat larger than other wheat-flower, and somewhat softer in the dough. A bushel of white cone-wheat will make considerably more bread than a bushel of lammas-wheat; but it gives it somewhat of a yellowish cast.

*Smyrna-WHEAT*, a peculiar kind of wheat that has an extremely large ear, with many lesser or collateral ears coming all round the bottom of the great one.

As this is the largest of all sorts of wheat, so it will dispense with the nourishment of a garden, without being overfed, and requires more nourishment

ment than common husbandry in the large way can give it. In the common way, its ears grow not much larger than those of the common wheat.

This sort of wheat seems, of all others, the most proper for the new method of horse-hoeing husbandry, as that method seems capable of giving as much nourishment as the farmer pleases, by often repeating the hoeing. Next to this, the white-cone wheat is best for this sort of husbandry; then the grey-cone wheat.

WHEAT-EAR, in ornithology, the English name of a species of motacilla, with a grey, black, and white forehead. See the article MOTACILLA.

WHEEL, *Rota*, in mechanics, a simple machine, consisting of a round piece of wood, metal, or other matter, which revolves on an axis. The wheel is one of the principal mechanic powers; it has place in most engines; in effect, it is of an assemblage of wheels that most of our engines are composed. For the theory of this mechanic power, called axis and wheel, see *AXIS in Petrochio*.

For the theory of clock-wheels, watch-wheels, mill-wheels, &c. see the articles CLOCK, MILL, &c.

With regard to the wheels of coaches, waggons, &c. otherwise called wheel-carriages, the whole doctrine thereof may be reduced to the following particulars; viz. 1. Wheel-carriages meet with less resistance than any other. 2. The larger the wheel, the easier is the draught of the carriage. 3. A carriage upon four wheels of equal size, is drawn with less force than with two of those wheels and two of a lesser size. 4. If the load be laid on the axle of the larger wheels, it will be drawn with less force than if it had laid on the axis of the lesser wheels, contrary to the common notion of loading carriages before. 5. The carriage goes with much less force on friction wheels than in the common way, all which will be confirmed by experiments. The wheels of carriages must be exactly round, and the fellys should be at right angles to the naves, according to the inclination of the spokes; that is, the plane of the curvature of the wheel should cut the nave at right angles, though it need not pass through the space where the spokes are inserted into the nave, 1. It is a general rule in all cases that the wheels be exactly round; for if they were not so, but like EFGH (plate XCV. fig. 1.) and the nave out of the center, it is certain, that such a wheel in turning, would be affected in the same manner upon plane ground as other wheels are when they rise and fall, and would not be in equilibrio; the wheel turning towards H would move with as much difficulty as if there was a rise to ascend; and that height being passed, it would fall on a sudden, as if a square stone was rolled along, and the jolts of the wheel

would precipitate and push the horses at one time, and immediately increase their difficulty of drawing the next moment, and that in proportion to the wheels being out of round: yet if the nave should not be in the middle, the shortest part, as F, being on the ground; when such a wheel begins to turn, the weight must be raised in the same manner as when another carriage is going up an hill: and from F to D, or quite to G, the wheel would act like a wedge; and at D, or G, it would fall and drive on the horses as in a steep descent.

2. The fellys must not cross wind, but be at right-angles with the naves, according to the inclination of the spokes; for otherwise the wheel, in turning, would find inequalities, as it happens when the hole of the nave is too big, and the wheel moves from side to side; which comes to the same purpose as if the wheel was out of round; and when the inequality of the spokes, which would be too leaning or too straight, upon the nave descending into a hole, or rising upon an eminence, opposite to their inclination, would cause them, or the fellys, to break.

3. The spokes must be inclined to the naves, that the wheels may be dishing or concave. If the wheels always turned upon smooth and even ground, it is certain that the spokes ought to be straight upon the naves; that is, at right-angles to their axes; because then they would bear perpendicularly, like the spoke B (fig. 2.) of the nave AC, which is the strongest way for wood.

But because the ground is unequal, and when the wheels fall into the ruts, that wheel which is in the rut bears a greatly part of the weight than the other, because it is lower: in such case, the spokes of a dishing-wheel become perpendicular in the rut, and therefore have the greatest strength; whilst the opposite wheel, being upon higher ground, bears a less part of the weight; and, consequently, the spokes need not be at their full strength, and so will have a sufficient force, though that force be less than what they have upon even ground.

4. The axle-tree must be straight in all respects, and at right-angles to the shafts or to the pole. In the motion of all bodies, there is one way of moving which is the easiest of all the rest, and happens here when the axle-tree is every way straight; for if its ends should bend backwards, so as bring the wheels nearer together behind, as AE (fig. 3.) and spread them much before, as DC, it is certain that they could not go into the ruts, nor turn in going forward, or at least with great difficulty, dragging instead of rolling.

There would be the same inconveniences in bending the axle-tree forward, so as to bring them nearer the pole, as IF (fig. 4.) and make them spread behind, as at BD.

The less the axle-tree is bent, the less the inconvenience;

*Handwritten text, possibly a title or date, is faintly visible at the top center of the page.*

# Wheel Carriages.

venience: but there will always be some, when the wheels are not parallel, and there will be no inconvenience when the axle is straight, and the wheels are in the situation CP and AD (fig. 5.) The axle must also be at right-angles to the pole or shafts; for if the pole or shafts were on one side, as at B (fig. 3.) or C (fig. 4.) the coach or carriage would be drawn on one side, and almost all the weight would bear upon one horse; but it must be at right-angles like the pole G (fig. 5.)

5. Great wheels are always more advantageous for rolling than little ones, in any case, or upon any ground whatsoever. The wheels of carriages are considered according to the velocity and friction they have upon the axle-tree, and likewise according to their resistance, or sinking in upon the ground.

If we consider them according to the friction, it is certain, that a wheel whose diameter is double that of another, will make but one turn, whilst the little one makes two for the same length of way; the circumference, which is in proportion to the diameter, being double. Therefore, in respect to friction, a wheel of double the diameter will have a double advantage, there being but one turn instead of two, which doubles the friction in the small wheel. The wheel ABC, being twice as big as the wheel DEF (fig. 6. and 7.) will have twice the advantage in respect of the friction, the holes of the nave and axles being equal. See the articles CIRCUMFERENCE and FRICTION.

If we consider the wheels according as they sink into the earth, or fall into holes, there will be the same advantage for one, and inconvenience for the other. If we consider the bearing, it is double in the great wheel; therefore it will sink but half the way: and if we consider hollows, it will give the same advantage in some cases; but then, in others, as, for example, where the holes are deep, the little wheel will have much more disadvantage: for if it should fall into a great hole, as DE (fig. 6, 7, and 8.) of a diameter equal to that of the wheel, it would wholly sink in whilst the great wheel would only fall in the depth of its segment AB, which would not be half the wheel, as may be seen from the parallel lines AD and BE.

We may suppose the same to happen in marshy grounds, where a little wheel would sink wholly in the same hole that a great one would sink but in part.

EF (fig. 8.) is a cart, or carriage; BD, a rub for the wheel CAD to pass over; AB, the horizontal plane; DB, AC, perpendicular, and OD parallel, to AB, C the center of the wheel. Then the horizontal force required to pull the wheel over the rub BD, is as  $\frac{DO}{CO}$ ; and the difficulty of going over rubs increases in a greater ratio than that of

their heights. Also, the higher the wheels, the more easily they pass over them; but then they are the more apt to overturn.

To draw the cart with the least power over the rub BD, it should not be drawn in the horizontal direction AB or OD, but in the direction AD. The advantage then of high wheels is, that they pass the rubs most easily, have the less friction, sink less in the dirt, and more easily press down an obstacle; and their disadvantage is, that they easily overturn, and make cattle draw too high; for they can apply their strength best when they draw low and upwards in the direction AD, which is the advantage of low wheels: yet if the wheels are high, they may be made to draw low, by fixing the limbers or traces as far below the axle as you will, which will then be an equal advantage with low wheels: for the power not pulling at the wheel, but at the carriage, may draw from any part of it. There is another advantage, which is, that they are better to turn with.

A waggon with four wheels is more advantageous than a cart with two wheels, especially on sand, clay, &c. Narrow wheels and narrow plates are a disadvantage.

Suppose the waggon FG (fig. 9.) is moved forward by a power acting within it, which power turns the wheel DE, by the spokes AD, AD, &c. and DE turns the wheel IC, which carries the waggon. Let the power at A be 1, then the force acting at E will be  $\frac{DA}{DE}$ . Also, if the power

at E be 1, the force at C, by which the waggon is moved, will be  $\frac{BE}{BC}$ ; therefore the power at A, to the force with which the waggon can be moved, is as 1 to  $\frac{DA \times BE}{DE \times BC}$ ; or the power is to that force, as  $DE \times BC$ , to  $DA \times BE$ .

It will be the same thing if, instead of teeth, the wheel DE carries EB by a chain going round them. You must suppose the like wheels on the opposite side. Hence, if the absolute force to move the waggon without, be 1, the force within applied at A to move it, will be  $\frac{DE \times BC}{BE \times DA}$ .

6. It would be much more advantageous to make the four wheels of a coach or waggon large, and nearly of a height, than to make the fore-wheels of only half the diameter of the hind-wheels, as is usual in many places, which the following experiment will confirm.

Let us make use of a little waggon, or model, of an inch to a foot (represented in fig. 10.) with the four wheels of five inches and nine lines; and so contrived that one may put on wheels of different diameters; as, for example, four of five inches, two of two inches three lines, two others of three inches, and

and let them have naves, spokes, and fellies, in proportion, to represent the wheels of a coach or waggon: let them be changed one after another, the waggon DB being always loaded with the same weight, A, of five pounds, and drawn by means of a silken thread running over a pulley, with a little bag, or scale of a ballance, to put in balls for the different wheels, according as they are to run upon even ground, upon earth, sand, or pavement. The board AF must be of oak, three feet long, plained on one side, and carved on the other, to imitate the pavements and the channels of streets. The paving stones must be of seven or eight lines instead of seven or eight inches, reducing them from inches to lines, as the wheels are reduced from feet to inches. It must be so contrived that the pulley may be turned to either side of the board. The whole being so disposed, the several experiments will answer a table, for which we refer the reader to Defagulier's Course of Experimental Philosophy, vol. i. page 223.

**WHEEL** is also the name of a kind of punishment which great criminals are put to in divers countries. In France, their assassins, parricides, and robbers on the highway, are condemned to the wheel; i. e. to have their bones first broken with an iron bar on a scaffold, and thus to be exposed, and left to expire on the circumference of a wheel. In Germany they break their bones on the wheel itself.

**WHEEL**, in the military art, is the word of command, when a battalion or squadron is to alter its front either one way or the other. To wheel to the right, directs the man in the right angle to turn very slowly, and every one to wheel from the left to the right, regarding him as their center; and *vice versa*, when they are to wheel to the left. When a division of men are on the march, if the word be to wheel to the right or to the left, then the right or left hand man keeps his ground; only turning on his heel, and the rest of the rank move about quick till they make an even line with the said right or left hand man.

**WHEEL-ANIMALS**, *Brachionus*, a genus of animalcules which have an apparatus of arms for taking their prey. This apparatus has been supposed by microscopical writers, to be a kind of wheels; and thence named the creatures that are possessed of it wheel-animals.

**WHEEZING**, the name of a distemperature in horses, accounted by the generality of people to be the same with that called purfiveness. See **PURFIVENESS**.

**WHELP**, the young of a dog, fox, lion, or any wild beast. Nothing is more essential to the having a good pack of hounds, than a proper care of the whelps, and of the parents from which they are to be bred. The bitches in particular should

be carefully chosen, and should be such as are strong and well proportioned; they must also have large ribs and flanks.

The whelps must have good fresh straw to lie in, and it must be often changed; they are to be kept in a place where neither the rain nor sunshine can be troublesome to them, and once a week it will be proper to anoint them all over with a little nut-oil, with some saffron infused in it. This will prevent the flies from annoying them so much as they otherwise would, and will kill worms of all kinds. When they are fifteen days old it is the custom to worm them, and a week after, one joint of their stern should be twisted off. As soon as they can see, they should have milk given them to lap; and at two months old, they should be weaned, keeping them wholly from the bitch. They must at this time be well kept, but not too high-fed; and it is proper to put some cummin seed into their food, to keep the wind out of their bellies.

**WHELPS**, in a ship, the seaman's term for those brackets which are set up on the capstan close under the bars; they give the sweep to it, and are so contrived, that the cable winding about them may not surge so much as it might otherwise do, if the body of the capstan were quite round and smooth.

**WHETSTONE**, *Cos*, a stone which serves for the whetting of knives and other tools upon.

**WHEY**, The serum, or watery part, of milk.

**WHIFFLER**, of a company, in London, a young freeman who goes before, and waits on the company on solemn assemblies.

**WHIG**, a party in England opposite to the tories, from whom they differ chiefly in their political principles. See **TORIES**.

The names of whig and tory were not known till about the middle of the reign of Charles II. when these were given as party distinctions. These parties may be considered either with regard to the state, or to religion. The state tories are either violent or moderate: the first would have the king to be absolute, and therefore plead for passive obedience, non resistance, and the hereditary right of the house of Stuart. The moderate tories would not suffer the king to lose any of his prerogative; but then they would not sacrifice those of the people. The state whigs are either strong republicans or moderate ones. The first, says Rapin, are the remains of the party of the long parliament, who attempted to change the monarchy to a commonwealth: but these make so slender a figure, that they only serve to strengthen the party of the other whigs. The tories would persuade the world, that all the whigs are of this kind; as the whigs would make us believe that all the tories are violent. The moderate state whigs are much in the same sentiments with the moderate

tories,

ories, and desire that the government may be maintained on the ancient foundation: all the difference is, that the first bear a little more to the parliament and people, and the latter to that of the king. In short, the old whigs were always jealous of the incroachments of the royal prerogative; and watchful over the preservation of the liberties and properties of the people.

In regard to religion, the whigs have always been for limiting the power of the bishops, and abolishing the convocation.

**WHIN**, a name used in the northern parts of England for the ulex, or furze. See the article **ULEX**.

**WHIP**, or **WHIP-STAFF**, in a ship, a piece of timber, in form of a strong staff, fastened into the helm, for the steersman, in small ships, to hold in his hand, in order to move the rudder and direct the ship.

**WHIP-GRAFTING**. See the article **GRAFTING**.

**WHIRL-POOL**, an eddy, vortex, or gulph, where the water is continually turning round. In rivers these are very common, from various accidents, and are usually very trivial, and of little consequence. In the sea they are more rare, but more dangerous.

Sibbald has related the effects of a very remarkable marine whirl-pool among the Orcades, which would prove very dangerous to strangers, though it is of no consequence to the people who are used to it. This is not fixed to any particular place, but appears in various parts of the limits of the sea among those islands. Wherever it appears it is very furious; and boats, &c. would inevitably be drawn in and perish with it; but the people who navigate them are prepared for it, and always carry an empty vessel, a log of wood, or large bundle of straw, or some such thing, in the boat with them: as soon as they perceive the whirl-pool, they toss this within its vortex, keeping themselves out. This substance, whatever it be, is immediately received into the center and carried under-water; and as soon as this is done, the surface of the place where the whirl-pool was, becomes smooth, and they row over it with safety; and in about an hour they see the vortex begin again in some other place, usually at about a mile distant from the first. See the articles **EDDY** and **VORTEX**.

**WHIRL-WIND**, a wind that rises suddenly, exceeding rapid and impetuous when risen, but soon spent.

There are divers sorts of whirl-winds, distinguished by their peculiar names; as the prester, typho, turbo, exhydria, and ecnephas.

The prester is a violent wind, breaking forth with flashes of lightning. This is rarely observed; scarce ever without the ecnephas. Seneca says, it is a typho or turbo kindled or ignited in the air.

The ecnephas is a sudden and impetuous wind, breaking out of some cloud, frequent in the Ethiopic sea, particularly about the Cape of Good-Hope. The seamen call them travados.

The exhydria is a wind bursting out of a cloud with a great quantity of water. This only seems to differ in degree from the ecnephas, which is frequently attended with showers.

A typho, or vortex, most properly called whirl-wind, or hurricane, is an impetuous wind, turning rapidly every way, and sweeping all round the place. It usually descends from on high. It is frequent in the Eastern-ocean, chiefly about Siam, China, &c. and renders the navigation of those parts exceeding dangerous.

**WHISPERING PLACES**, depend upon this principle: if the vibrations of the tremulous body are propagated through a long tube, they will be continually reverberated from the sides of the tube into its axis, and by that means prevented from spreading, till they get out of it; whereby they will be exceedingly increased, and the sound rendered much louder than it otherwise would be.

Hence it is, that sound is conveyed from one side of a whispering-gallery to the opposite one, without being perceived by those who stand in the middle.

The form of a whispering-gallery is that of a segment of a sphere, or the like arched figure; and the progress of the sound through it may be illustrated in the following manner:

Let *ABC* (plate *XCIII. fig. 4.*) represent the segment of a sphere; and suppose a low voice uttered at *D*, the vibrations-expanding themselves every way, some will impinge upon the points *E, E*, &c. and from thence be reflected to the point *F*, from thence to *G*, and so on till they all meet in *C*, and by their union there, cause a much stronger sound than in any part of the segment whatever, even at *D*, the point from whence they came. Accordingly, all the contrivance in whispering places is, that near the person that whispers there may be a smooth wall, arched either cylindrically or elliptically. A circular arch will do, but not so well.

The most considerable whispering places in England are, the whispering-gallery in the dome of St. Paul's, London, where the ticking of a watch may be heard from side to side, and a very easy whisper be sent all round the dome. The famous whispering place in Gloucester cathedral, is no other than a gallery above the east end of the choir, leading from one side thereof to the other. It consists of five angles and six sides, the middlemost of which is a naked window, yet two whisperers hear each other at the distance of twenty-five yards.

**WHIST**, a well-known game at cards; so called from the silence observed during the play, which is like that of honours and ruff.

However, as there are many ways of cheating practised in this game, we shall only mention a few.

to put the unwary upon their guard. Some by winking, shutting their eyes, placing their fingers, or other signs, find means to let their partners know what honours they have got: others have a way of cutting honours either to their partners or to themselves: the dealer is often crafty enough to conceal some honours for himself: but the best way of rooking is by means of brief cards; for all the honours being somewhat broader than the rest, your adversary must always cut you an honour. See the article *HONOURS and Ruff*.

**WHITE**, one of the colours of natural bodies. White is not so properly said to be any one colour, as a composition of all colours; for it is demonstrated by Sir Isaac Newton, that those bodies only appear white, which reflect all the kinds of coloured rays alike. See the article **WHITENESS**.

**WHITE**, in painting in miniature, &c. The best white for painting in water-colours, is flake white, which is better than white lead; and if it be pure, far exceeds it in beauty; because white lead is apt to turn blackish, especially if it be used in a hard water: but if you use white lead, first rectify it with white wine vinegar in the following manner: grind well the finest white lead upon a porphery with vinegar; then put it into a glass of water, stir it about, and presently pour off the water, while it is white, into some other clean glass, or vessel; let it settle, and then pour off the water from it, and it will be exceeding fine. When this white is settled, put to it gum water, to bind it, and to give it a glaze.

Some recommend a white made of the whiter part of oyster shells, reduced into an impalpable powder; this is called pearl-white, and will mix with any colour. Some also recommend the powder of egg-shells of the brightest colour, and well cleaned and washed, ground with gum-water, to which may be added about a twentieth part of white sugar-candy: the egg-shells should be ground to an impalpable powder.

Experience shews, that egg-shell powder is of very great service as a white in water-colours, and both that and the powder of oyster-shells, well rectified and mixed with the white of an egg well beat, will make an extraordinary mixture in other colours, and will correct them from changing or altering their qualities.

**WHITE of the Eye**, denotes the first tunic or coat of the eye, called albuginea and conjunctiva, because it serves to bind together or inclose the rest. See the article **EYE**.

**WHITE-HART-SILVER**, a mulct or tribute paid into the Exchequer, out of certain lands in or near the forest of White-hart in Dorsetshire; imposed by Henry III. upon Thomas de la Linde, for killing a beautiful white hart which that prince had before spared in hunting.

**WHITE-LEAD**, also called ceruse. See the article **CERUSE**.

**WHITE-LINE**, among printers, a void space of the depth or breadth of a line. See the article **PRINTING**.

**Spanish-WHITE**, a kind of fucus used by ladies to heighten their complexion, and hide its defects. It is made of tin-glass dissolved in spirit of nitre, and precipitated into a very fine powder by means of salt water. See the article **TIN**.

**WHITENESS**, *Albedo*, the quality which denominates a body white. Sir Isaac Newton shews, that whiteness consists in a mixture of all the colours; and that the light of the sun is only white, because consisting of rays of all colours.

From the multitude of rings of colours which appear, upon compressing two prisms or object-glasses of telescopes together, it is manifest that these do so interfere and mingle with one another at last, as, after eight or nine reflections, to dilute one another wholly, and constitute an even and uniform whiteness; whence, as well as from other experiments, it appears, that whiteness is certainly a mixture of all colours, and that the light which conveys it to the eye, is a mixture of rays endued with all those colours.

The same author shews, that whiteness, if it be most strong and luminous, is to be reckoned of the first order of colours; but if less, as a mixture of the colours of several orders. Of the former sort, he reckons white metals; and of the latter, the whiteness of froth, paper, linen, and most other white substances. And as the white of the first order is the strongest that can be made by plates of transparent substances, so it ought to be stronger in the denser substances of metals, than in the rarer ones of air, water, and glass.

Gold, or copper, mixed either by fusion or amalgamation, with a very little mercury, with silver, tin, or regulus of antimony, becomes white, which shews both that the particles of white metals have much more surface, and therefore are smaller than those of gold and copper; and also, that they are so opaque, as not to suffer the particles of gold or copper to shine through them. And as that author doubts not but that the colours of gold and copper are of the second and third order, therefore the particles of white metals cannot be much bigger than is requisite to make them reflect the white of the first order. See the article **LIGHT**.

**WHITING**, in ichthyology, the English name for the white gadus with no beard, with three fins on the back, and the upper jaw longest. See the article **GADUS**.

**WHITING-POLLOCK**, in ichthyology, a species of gadus with three back fins, the lower jaw longest, and the lateral line crooked. The usual length of this fish is from eight to thirteen inches; it is considerably

## W I C

considerably thick in proportion, and in most other respects resembles the common whiting.

**WHITES**, in medicine, the same with fluor albus. See the article **FLUOR ALBUS**.

**WHITLOW**, in medicine. See the article **PARONICHIA**.

**WHITSUNDAY**, a solemn festival of the Christian church, observed on the fiftieth day after Easter, in memory of the descent of the Holy Ghost upon the apostles, in the visible appearance of fiery cloven tongues, and of those miraculous powers which were then conferred upon them.

It is called Whitsunday, or White-sunday, because this being one of the stated times for baptism in the ancient church, those who were baptised put on white garments, as types of that spiritual purity they received in baptism. As the descent of the Holy Ghost upon the apostles happened upon the day which the Jews called Pentecost, this festival retained the name of Pentecost among the Christians. See the article **PENTECOST**.

**WHOODINGS**, or **HOODINGS**, a sea term, used for planks joined and fastened along the ship's sides into the stem.

**WHORLBAT**, or **HURLBAT**, a kind of gauntlet, or leathern strap, loaden with plummets; used by the ancient Romans in their solemn games and exercises, and by them called *cæstus*. See the article **CÆSTUS**.

**WHORTLE-BERRY**, in botany. See the article **VACCINIUM**.

**WIC**, a place on the sea shore, or on the bank of a river; though it properly signifies a town, village, or dwelling place; and sometimes a machine.

**WICKER**, a twig of the osier shrub, single or wrought.

**WICKET**, a small door in the gate of a fortified place, or a hole in a door, through which to view what passes without.

**WICKLIFFISTS**, or **WICKLIFFITES**, a religious sect, which sprang up in England in the reign of Edward III. and took its name from John Wickliff, doctor and professor of divinity in the university of Oxford, who maintained that the substance of the sacramental bread and wine remained unaltered after consecration; and opposed the doctrine of purgatory, indulgences, auricular confession, the invocation of saints, and the worship of images.

He maintained, that the children of the religious may be saved without being baptized; that priests may administer confirmation; that there ought to be only two orders in the church, that of priests, and that of deacons. He made an English version of the Bible, and composed two volumes, called *Aletheia*, that is, Truth; from which John Huffle learned most of his doctrines. In short, to this reformer, we owe the first hint of the Reformation, which was effected about two hundred years after. See **REFORMATION**.

## W I L

**WIDOW**, a woman who has lost her husband. In London, a freeman's widow may exercise her husband's trade, as long as she continues such.

Marriage with a widow, in the eye of the canon law, is a kind of bigamy. See **BIGAMY**.

*WIDOW of the King*, was she who after her husband's death, being the king's tenant in capite, could not marry again without the king's consent. See **CAPITE**.

**WIFE**, a married woman, or one joined with, and under the protection of, a husband. See **HUSBAND**.

A wife, in our English law, is termed *feme covert*; and, in the judgment of the law, is reputed to have no will, as being supposed entirely under, and subject to, that of her husband. See **COVERTURE** and **BARON and FEME**.

The wife can make no contract without the husband's consent; and if any goods or chattels be given her, they all immediately become her husband's: even necessary apparel is not her's in property. All her personal chattels, which she held at her marriage, are so much her husband's, that after his death they shall not return to her, but go to the executor or administrator of her husband, except only her paraphernalia. See **PARAPHERNALIA**.

The wife partakes of the honour and condition of her husband; but none of her dignities come by marriage to her husband; and as the law supposes the husband to have the full power over his wife, he is obliged to answer for all her faults and trespasses.

If a wife bring forth a child begot by a former husband, or any other before marriage, but born after marriage with another man, this latter must own the child; and that child shall be his heir at law: and if a wife bring forth a child during her husband's absence, though it be of many years, yet if he lived all the time within the island, he must father the child, and the child, if first born, shall inherit.

If a wife has a jointure, and during her marriage is made pregnant by her husband, which must appear by the child's being born alive, the husband shall have all his wife's lands for life; but if the wife have no jointure settled before marriage, she may, after her husband's death, challenge the third part of his yearly rents of land, during her life. See **JOINTURE**.

**WILDS**, a term used by our farmers to express that part of a plough by which the whole is drawn forwards.

**WILDERNESS**, in gardening, a kind of grove of large trees, in a spacious garden, in which the walks are made either to intersect each other in angles, or have the appearance of meanders and labyrinths. See **GROVE** and **LABYRINTH**.

Wildernesses, says Mr. Miller, should always be proportioned to the extent of the gardens in which they are made; for it is very ridiculous to see a large wilderness planted with tall trees, in a small spot of ground;

ground; and, on the other hand, nothing can be more absurd, than to see little pauntry squares, or quarters of wilderness work, in a magnificent large garden. As to the situation of wildernesses, they should never be placed too near the habitation, nor so as to obstruct any distant prospect of the country; there being nothing so agreeable as an unconfined prospect; but where from the situation of the place, the sight is confined within the limits of the garden, nothing can so agreeably terminate the prospect, as a beautiful scene of the various kinds of trees judiciously planted; and if it is so contrived, that the termination is planted circularly, with the concave towards the sight, it will have a much better effect, than if it end in strait lines or angles. The plants should always be adapted to the size of the plantation; for it is very absurd for tall trees to be planted in the small squares of a little garden; and in large designs small shrubs will have a mean appearance. It should also be observed, never to plant ever-greens amongst deciduous trees; but always to place the evergreens in a wilderness in a separate part by themselves, and that chiefly in sight.

As to the walks, those that have the appearance of meanders, where the eye cannot discover more than twenty or thirty yards in length, are generally preferable to all others, and these should now and then lead into an open circular piece of grass; in the center of which may be placed either an obelisk, statue, or fountain; and, if in the middle of the wilderness there be contrived a large opening, in the center of which may be erected a dome or banquetting-house surrounded with a green plot of grass, it will be a considerable addition to the beauty of the whole. From the sides of the walks and openings, the trees should rise gradually one above another to the middle of the quarters, where should always be planted the largest growing trees, so that the heads of all the trees may appear to view, while their stems will be hid from the sight. Thus in those parts which are planted with deciduous trees, roses, honey-suckles, spiræa frutex, and other kinds of low flowering shrubs, may be planted next the walks and openings; and at their feet, near the sides of the walks, may be planted primroses, violets, daffodils, &c. not in a strait line, but so as to appear accidental, as in a natural wood. Behind the first row of shrubs should be planted syringas, althæa frutex, mezereons, and other flowering shrubs of a middle growth; and these may be backed with many other sorts of trees, rising gradually to the middle of the quarters.

The part planted with ever-greens, may be disposed in the following manner, viz. in the first line next the great walks, may be placed the laurus-tinus, boxes, spurge-laurel, juniper, savin, and other dwarf ever-greens. Behind these may be placed laurels,

hollies, arbutuses, and other ever-greens of a larger growth. Next to these may be planted alaternuses, phyllireas, yews, cypresses, Virginian cedars, and other trees of the same growth; behind these may be planted Norway and silver firs, the true pine, and other sorts of the fir growth; and in the middle should be planted Scotch pines, pinaster, and other of the larger growing ever-greens, which will afford a most delightful prospect, if the different shades of the greens are curiously intermixed.

But beside the grand walks and openings (which should always be laid with turf, and kept well mowed) there should be some smaller serpentine walks through the middle of the quarters, where persons may retire for privacy; and by the sides of these private walks may also be scattered some wood flowers and plants, which, if artfully planted, will have a very good effect.

In the general design for these wildernesses, there should not be a studied and stiff correspondence between the several parts; for the greater diversity there is in the distribution of these, the more pleasure they will afford.

**WILL**, or *last WILL*, in law, signifies the declaration of a man's mind and intent relating to the disposition of his lands, goods, or other estate, or of what he would have done after his death.

In the common law, there is a distinction made between a will and a testament; as that is called a will, where lands or tenements are given; and when the disposition concerns goods and chattels alone, it is termed a testament. See the article **TESTAMENT**.

A will, though it has no force (till after the testator's decease, does then without any other grant, or livery, &c. give and transfer estates, and alter the property either of lands or goods, as effectually as any deed or conveyance executed in a person's life-time, and thereby descents may be prevented, estates in fee, tail, for life, or for years, be made; and he that takes lands by device is in the nature of a purchaser. Formerly a person could not give away by will those lands that he had by descent, though he might such as he enjoyed by way of purchase; but by 34 and 35 of Hen. VIII. c. 5. all persons that have a sole estate in fee simple of any lands, tenements, &c. may devise the same by will, at their pleasure, to whom they think fit; and this extends to persons seized in coparcenary, or as tenants in common; but lands intailed are not deviseable, only those held in fee, and goods and chattels: but wills made by infants or feme coverts, idiots, and persons not of sound memory, are deemed not good in law. The 29 Car. II. c. 23. has enacted, that wills and devises of lands, &c. shall be in writing, signed by the devisor, or some other by his express directions, in the presence of at least three credible witnesses; and

and no will made in writing shall be revoked, but by another will, or cancelling the same by the testator himself, or by his direction.

In the making of a will there are these several rules to be observed, viz. 1. That it be done while the testator is of sound mind and memory. 2. That there be two parts thereof, the one to remain in the hands of the party that made it; and the other in the custody of some friend, in order to render it less liable to be suppressed after the testator's death. 3. That the whole be written in one hand writing, and, if possible, in one sheet of paper or parchment. 4. In case there be more sheets than one, that the testator sign and seal every sheet, before the witnesses present at the execution.

**WILL** with a wisp, or *Jack with a lantern*, a meteor known among the people under these names, but more usually among authors under that of ignis fatuus. See the article **METEOR**.

This meteor is chiefly seen in summer nights, frequenting meadows, marshes, and other moist places. It seems to arise from a viscous exhalation, which being kindled in the air, reflects a sort of thin flame in the dark, without any sensible heat.

It is often found flying along rivers, hedges, &c. by reason it there meets with a stream of air to direct it. The ignis fatuus, says Sir Isaac Newton, is a vapour shining without heat; and there is the same difference between this vapour and flame, as between rotten wood shining without heat, and burning coals of fire.

**WILLOW**, *Salix*, in botany, a genus of trees, producing male and female flowers on separate plants; they are disposed in oblong imbricated katkins, and are both destitute of petals; the male flower consists of a cylindric nectarious honey gland in the center of each scale; the stamina are two slender erect filaments, topped with quadrilocular twin antheræ; the female flower contains an ovate narrow germen, crowned by two bifid erect stigmas; the fruit is an oval, awl-shaped, unilocular capsule, opening with two revolute valves, and containing many small ovate seeds crowned with a hairy down.

There are various kinds of willows, some of which grow to the size of a large tree, while other sorts are of a more humble growth; they all delight in moist marshy places, and on the sides of brooks and rivers. The propagation of willows is easily effected either by sets or cuttings: those sorts which are cultivated for their timber are generally planted from branches eight or nine feet long; these are commonly sharpened at their lower end, and thrust into the ground by the sides of ditches and banks where the ground is moist, in which they will freely grow. The best season for planting is early in the spring, though they will succeed if planted in autumn.

Willow is of use to make wooden heels for shoes, for cricket bats, as also to the turners in many

kinds of light wares; the loppings are used for several purposes; and the osier which belongs to this genus is the most proper for making baskets. See **OZIER**.

The bark, leaves, and katkins, are said to be cooling and astringent; the leaves externally are of service in baths for the feet, in order to procure sleep, and cool the heat of fevers; the bark has the like virtues; and the ashes thereof are reckoned effectual in extirpating warts and corns.

**WIN**, in the beginning or end of the names of places, signifies that some great battle was fought, or a victory gained there.

**WIND**, *Ventus*, in physiology, a stream of air, flowing out of one place, or region, into another. See the article **AIR**.

As the air is a fluid, its natural state is that of rest, which it endeavours always to keep or retrieve by an universal equilibrium of all its parts. When, therefore, this natural equilibrium of the atmosphere happens by any means to be destroyed in any part, there necessarily follows a motion of all the circumjacent air towards that part to restore it; and this motion of the air is what we call wind.

Hence, with respect to that place where the equilibrium of the air is disturbed, we see the wind may blow from every point of the compass at the same time; and those who live Northwards of that point, have a Northwind; these who live Southwards, a South-wind; and so of the rest: but those who live on the spot, where all these winds meet and interfere, are oppressed with turbulent and boisterous weather, whirl-winds, and hurricanes; with rain, tempest, lightening, thunder, &c. For sulphureous exhalations from the south, torrents of nitre from the North, and aqueous vapours from every part are there confusedly huddled, and violently blended together, and rarely fail to produce the phenomena above mentioned. See **RAIN**, **LIGHTNING**, &c.

Many are the particular causes which produce wind by interrupting the equipoise of the atmosphere; but the most general causes are two, viz. heat, which, by rarifying the air, makes it lighter in some places than it is in others; and cold, which, by condensing it, makes it heavier. Hence it is, that in all parts over the torrid zone, the air being more rarified by a greater quantity of the solar rays, is much lighter than in the other parts of the atmosphere, and most of all over the equatorial parts of the earth. And since the parts at the equator are most rarified, which are near the sun; and those parts are, by the earth's diurnal rotation eastward, continually shifting to the west; it follows, that the parts of the air which lie on the west side of the point of the greatest rarefaction; and, by flowing towards it, meet it, have less motion than those parts on the east side of the said point, which follow it; and therefore the motion of the eastern air

would

would prevail against that of the western air, and so generate a continual east-wind, if this were all the effect of that rarefaction. But we are to consider, that as all the parts of the atmosphere are so greatly rarified over the equator, and all about the poles greatly condensed by extreme cold, this heavier air from either pole is constantly flowing towards the equator, to restore the ballance destroyed by the rarefaction and levity of the air over those regions: hence, in this respect alone, a constant north and south wind would be generated.

We find by experience, that people in general have but an obscure idea or confused notion of the cause of this perpetual current of air from east to west, or of a constant east wind under the equator.

Therefore, in order to elucidate this matter, we shall explain it by a figure. Let C B A D E (plate XCVI. fig. 1. N° 1.) be part of a section of the atmosphere over the equator, C the east, E the west, A the point to which the sun S is vertical, and R the point of the greatest rarefaction, or that where the air is most of all heated, and consequently, lightest. That this point R is on the eastern side of the point A, is not difficult to be conceived, when what is said under the article TIDE, is well considered. And, because the air at R is by supposition lighter than where it is colder at C and D, it is plain that in order to obtain an equilibrium (which is necessary in a fluid body) the air, by its greater weight, will have a tendency from C and D towards R, and rise to a height there greater than at C or D, in proportion as its density is less.

Now this being the case, it is evident, the sun, being always between the points R and D, will be heating the air on that part; and those regions between R and C, having been deserted by the sun, will grow cold: consequently, the air between C and R, as it is colder, will likewise be heavier than that between R and D which is hotter, and so will have a greater momentum, or quantity of motion, towards the point R; and since this point R is constantly moving after the point A westward, the motion of the western air towards it, will be in part diminished by that means; and being also inferior in quantity to the motion of the eastern air, the latter will prevail over it, and be constantly following the said point R from east to west, and thus produce a continual east wind.

It may, perhaps, be here said, that though the motion of the air be less from D to R, yet it is something, and so there ought to be a western wind, at least in some degree, and to some distance westward of the point R. To which we answer, that the nature of a fluid will not permit two contrary motions to restore or sustain an equilibrium (we mean in regard of the whole body of it) for wherever one part of the fluid is determined to move, all the rest must necessarily follow it; otherwise the equilibrium of the air would be destroyed in one part to

make it good in another; a defect which nature cannot be guilty of. Thus, we see the tides of the ocean always follow the course of the moon from east to west, without any motion of the waters from the west towards the moon, in the open oceans; and the point R can only be considered as the ærial tide, or flood of high air; and has nearly the same phænomena with aqueous tides.

This being clearly understood, all the rest is easy; for no one can find it difficult to conceive how the cold air from each pole must necessarily set in towards the equator directly, where meeting and interfering with the eastern current, it does with that compound a new direction for the moving air which lies between both the former, viz. a north-east current on the north side, and a south-east on the south side: all which naturally results from the doctrine of the composition of oblique forces.

And this we find to be verified in the general trade-winds, which constantly blow from the north-east and south-east, to about thirty degrees on each side the equator, where those parts are over the open ocean, and not affected with the reflection of the sun-beams from the heated surface of the land; for in this case the wind will always set in upon the land, as on the coast of Guinea, and other parts of the torrid zone, we know it does.

*Velocity and Force of the WIND.* As the motion of the air has a greater or lesser velocity, the wind is stronger or weaker; and it is found from observation, that the velocity of the wind is various, from the rate of one to fifty or sixty miles per hour. The best way to prove this, is to chuse a free open place, where the wind or current of air is not at all interrupted, but flows uniformly, or as much so as the undulatory state of the atmosphere will admit: in such a place, a feather, or other very light body, is to be let go in the wind; and then, by a half-second watch, or pendulum, you must observe nicely to what distance it is carried in any number of half-seconds, or in how many half-seconds it has passed over a given or measured space. This will give the rate of velocity in the wind per second, and of course per hour; which has been found, at a medium, to be twelve or fifteen miles per hour; even the most vehement wind does not fly above fifty or sixty miles per hour; and sometimes the wind is so slow, as not to exceed the velocity of a person riding or walking in it; and in that case, if the person goes with the wind, he finds no wind at all, because there is no difference of velocity, or no relative wind, which is that only which we are sensible of, whilst in motion.

The best method to estimate the force of the wind, is by means of the following anemometer. A B C D E F G H I (fig. 1. N° 2.) is an open frame of wood, firmly supported by the shaft or postern I. In the cross-pieces H K, L M, is moved an horizontal axis Q M, by means of the four sails *ab*, *c d*,

*cd, ef, gh*, in a proper manner exposed to the wind. Upon this axis is fixed a cone of wood *MNO*, upon which, as the sails move round, a weight *S*, is raised by a string on its superficies, proceeding from the small to the largest end *NO*. Upon the great end or base of the cone is fixed a ratchet-wheel *ik*, in whose teeth falls the click *X*, to prevent any retrograde motion from the depending weight.

From the structure of this machine, it is easy to understand, that it may be accommodated to estimate the variable force of the wind, because the force of the weight will continually increase, as the string advances on the conical surface, by acting at a greater distance from the axis. And therefore, if such a weight be put on, on the smallest part at *M*, as will just keep the machine in equilibrio with the weakest wind; then, as the wind becomes stronger, the weight will be raised in proportion, and the diameter of the base of the cone *NO*, may be so large in comparison of that of the smaller end or axis at *M*, that the strongest wind shall but just raise the weight at the great end.

Thus, for example, let the diameter of the axis be to that of the cone *NO*, as 1 to 28, then if *S* be a weight of 1 pound at *M*, on the axis, it will be equivalent to 28 pounds, or  $\frac{1}{28}$  of an hundred, when raised to the greatest end. If, therefore, when the wind is weakest, it supports 1 pound on the axis, it must be 28 times as strong to raise the weight to the base of the cone. Thus may a line of 28 equal parts be drawn on the side of the cone, and the strength of the wind will be indicated by that number on which the string shall at any time hang.

The string may also be of such a size, and the cone of such a length, that there may be sixteen revolutions of the string betwixt each division of the scale on the cone, whence the strength of the wind will be expressed in pounds and ounces. And if greater exactness be required, let the periphery of the cone's base be divided into 16 equal parts; then, whenever the equilibrium happens, the string will leave the conic surface against one of those divisions, and thus shew the force of the wind to a dram avoirdupois weight.

**CARDINAL WINDS**, are those which blow from the east, west, north, and south, which are called cardinal points.

**COLLATERAL WINDS**, are those which blow between the cardinal points. The number of these is infinite, as the number of points they blow from are; a few of them only are considered in practice, and these have names compounded of the cardinal points between which they blow. See the article **COMPASS**.

**WIND-GUN, or AIR-GUN**. See the article **AIR-GUN**.

**WIND-MILL**, a kind of mill, the internal parts of which are much the same with those of a water-

mill; from which however it differs, in being moved by the impulse of the wind upon its vanes, or sails, which are to be considered as a wheel on the axle.

A description of the mechanism of this useful engine, will, no doubt, be acceptable to our readers. *AHO* (plate *XCVI*. fig. 2. *Nº*. 1.) is the upper room; *HOZ*, the under one; *AB*, the axle-tree, going quite through the mill; *STVW*, the sails, covered with canvas, set obliquely to the wind, and going about in the order *STVW*; *CD*, the cog-wheel, of about 48 cogs, *a, a, a*, &c. which carries round the lantern *EF*, of 8 or 9 trundles *c, c, c*, &c. together with its axis *GN*. *IK* is the upper mill-stone; and *LM*, the lower one. *QR* is the bridge, supporting the axis or spindle *GN*: this bridge is supported by the beams *cd*, *XY*, wedged up at *c, d*, and *X*. *ZY* is the lifting-tree, which stands upright; *ab, ef*, are levers, whose centers of motion are *Z* and *e*; *fghi* is a cord, with a stone *i*, going about the pins *g* and *h*, and serving as a balance or counterpoise.

The spindle *GN* is fixed to the upper mill-stone *IK*, by a piece of iron called the rind, and fixed in the under side of the stone; which is the only one that turns about, and its whole weight rests upon a hard stone, fixed in the bridge *QR*, at *N*.

The trundle *EF*, and axis *Gt*, may be taken away; for it fixes on the lower part at *t*, by a square socket, and the top runs in the edge of the beam *w*. Putting down the end *f*, of the lever *fe*, raises *b*, which raises *ZY*, which raises *YX*, and this raises the bridge *QR*, with the axis *NG*, and the upper stone *IK*; and thus the stones are set at any distance. The lower immoveable stone is fixed upon strong beams, and is broader than the upper one. The flour is conveyed through the tunnel *no*, down into a chest.

*P* is the hopper, into which the corn is put, which runs along the spout *r*, into the hole *t*, and so falls between the stones, where it is ground. The axis *Gt* is square, which shaking the spout *r*, as it goes round, makes the corn run out: *rs* is a string going about the pin *s*, and serving to move the spout nearer or farther from the axis, so as to make the corn-run faster or slower, according to the velocity and force of the wind. And when the wind is great, the sails *STVW* are only part, or on one side of them, covered; or, perhaps, only a half of two opposite sails.

Towards the end *B*, of the axle-tree, is placed another cog-wheel, trundle, and mill-stones, with exactly the same apparatus; so that the same axle-tree carries two stones at once: and when only one pair is to grind, the trundles *EF*, and axis *Gt*, is taken out from the other. *xy* is a girt of pliable wood, fixed at the end *x*; and the other end *y*, tied to the lever *km*, moveable about *k*. And the end *m* being put down, draws the girt *xy* close to the cog-wheel; whereby the motion of the mill is stop-

ped at pleasure:  $pq$  is a ladder going into the higher part of the mill; and the corn is drawn up by means of a rope, rolled about the axis  $AB$ , when the mill is going.

In mills built of wood, the whole body of the mill turns round to the wind, on a tampion, or perpendicular post; but in those of stone, only the upper part turns in this manner. See the mill-house represented (fig. 2. No. 2.) where  $r$  is the house itself, which is turned about to the wind by a man, with the help of the lever or beam  $z$ ;  $3$  is a roller, to hoist up the steps 4.

In those built of stone, only the roof  $E$  (fig. 2. No. 3.) together with axis and sails  $AB$ ,  $CD$ , turn round; in order to which, the roof is built turret-wise, the turret being encompassed with a wooden ring, in which is a groove, at the bottom of which a number of brass truckles are placed at certain distances; and within this groove is another ring, upon which the whole turret stands. To the upper or moveable ring are connected beams with a rope, by means of which, and a windlass below, the top of the machine, together with the sails, may be turned round, and put in the direction required.

*Position of, and Force of the Wind, upon the Sails.* As to the position of the sails, we must consider, that if they are placed direct to the wind, or at right angles to the axis of the mill, they will receive the whole force of the wind, which in this case will tend to blow them forward, and consequently to blow down the mill; which position of course cannot be admitted.

If the sails are set right to the wind, or parallel with the axis of the mill, it is plain, that in that position, the wind cannot act upon them at all, and therefore they cannot be turned round, nor the mill put in motion; which position of the sails must likewise be rejected.

Since neither the direct nor right position of the sails will do, an oblique position must, as there can be no other. Now, to shew that an oblique position of the sails will turn the mill, let  $AB$  (fig. 2. No. 4.) be the axis;  $CD$ , a sail, and its angle of obliquity (viz. that which it makes with the axis) be  $EGC$ ; then if  $GC$  be the force of the wind in the direct position of the sail,  $GE$  will be the force of the wind in its oblique position (as being the sign of the angle of incidence  $GCE$ ). But the force  $GE$  is resolvable into two others,  $EF$  and  $GF$ ; of which the latter, being parallel to the axis, avails nothing in turning the sail about it; but the other,  $EF$ , being perpendicular thereto, is wholly spent in compelling the sail to turn round: which was the thing to be shewn.

The force of the wind on the sail will be as the square of the sign of incidence, or as  $GE^2$ ; for the force of each single particle of air will be as the sign  $GE$ ; and it will be also as the number of particles which strike at the same time, which number of

particles is also as the sign of incidence  $GE$ . For let  $CD$  represent the section of the sail in a direct position, and  $CG$  the same in an oblique position; it is plain the number of particles striking it in the former case, will be to the number striking it in the latter, as  $CD$  to  $CF$ , which is equal to  $GE$ , the sine of incidence; for all the particles between  $AD$  and  $BF$ , will not come upon the sail in the oblique position  $CG$ . Since, then, the force of the wind on the sail is on two accounts as  $GE$ , it will be as the square of the said line  $GE$ .

If we suppose the velocity of the wind to vary, the force thereof will be as the square of the velocity; for the greater the velocity, the greater will be the stroke of each single particle, and also the greater will be the number of particles coming upon the sail in the same time; the force will be therefore as the squares of the velocity.

Again, if the area of the sail be variable, the force of the wind will be directly as the area or superficies of the sail; because the number of particles of the air coming upon it, will always be proportional thereto, and consequently the force with which they strike it. Hence, if  $A$ ,  $S$ , and  $V$ , represent the area, sine of incidence, and velocity of the wind on one sail; and  $a$ ,  $s$ , and  $v$ , those on another: the force compelling the former to turn round, will be to that compelling the latter, as  $A \times S^2 \times V^2$  to  $a \times s^2 \times v^2$ .

When the area of the sail and its position in respect to the wind, continue the same, the force which turns the sails will be as the squares of the velocity; and since the wind scarce ever blows with one uniform velocity, but varies with almost every blast, the force upon the sail will be much more variable and unequal; and therefore the action or working of a wind-mill cannot be so equal, uniform, or steady, as that of a water-mill, whose power is always of the same tenor, when the jet of water is so.

If the area of the sail and the velocity of the wind be supposed constant, the force of the wind in the direct position, will be to that in the oblique one, as  $GC^2$  to  $GE^2$ , as we have before shewn; and it has been also shewn, that that part of the force which turns the sail round is represented by  $EF$ , when  $GE$  is the whole force; but  $GE:EF :: GC:CE$  ::  $GE^2:CE \times GE$  ::  $CE \times GE^2$  to the force which turns the sail, when the whole force is represented by  $GE^2$ , as is here the proper expression of it.

This expression  $\frac{CE \times GE^2}{GC}$  begins from nothing, when the angle of incidence begins to be oblique, and increases with the obliquity of the said angle to a certain number of degrees; because that part of the force which is parallel to the axis, becomes lesser in proportion to that which is perpendicular to it: but

but after it has passed this limit, it again decreases, and becomes nothing, when the angle of incidence vanishes; as is easy to understand, by considering that the quantity of wind on the sail does in this case continually decrease.

There is therefore one certain position of the sail, in which the force of the wind is greatest of all upon it, or a maximum; and to find it, put radius  $GC = a$ ,  $EC = x$ , and we have  $CE^2 = aa - xx$ ; and, consequently, the force  $\frac{CE \times GE^2}{GC} = \frac{aa x - xxx}{a}$ ,

which must be a maximum: therefore, its fluxion  $aa x - 3xxx = 0$ ; whence  $aa = 3xx$ , and so  $x = \sqrt{\frac{aa}{3}}$ ; which in logarithms is

$\frac{20,000000}{2} - 0,477121 = 9,761439$ , which is the logarithm fine of the angle  $35^\circ 16' =$  the angle  $CGE$ ; and therefore the angle  $ECG$  is equal to  $54^\circ 44'$ , when the force of the wind is a maximum, as required.

The angle now found, is only that which gives the wind the greatest force to put the sail in motion, but not the angle which gives the force of the wind a maximum upon the sail when in motion. What this angle is, Mr. Mac Laurin has shewn in his book of Fluxions, to which we refer the reader.

Mr. Parent has also shewn, that an elliptic form of the sails is better than a parallelogram, or long square; and that the best position of the sail is not that which is common, viz. with its longest side or diameter parallel to the axis of the sail; but, on the contrary, it ought to be perpendicular to it; that is, they ought to be of such a form, and placed in such a manner, as represented fig. 2. N<sup>o</sup>. 5. And after the four sails B, C, D, E, are thus placed on the axis or arm A, they are then to be turned about, and fixed under the proper angle of obliquity above mentioned.

There are three things yet wanting to the perfection of a wind-mill. 1. Some contrivance in the nature of a fly, to regulate the motion of the train, under the unequal and irregular impulse of the wind. 2. Some other contrivance to supply the hopper, or stones, with more or less corn, in proportion to the greater or less strength of the wind. 3. A method of altering the angle of the sail's obliquity, from its maximum of  $54^\circ 44'$ , at the beginning of the motion, to its minimum, when in motion.

WIND, in the maege. A horse that carries in the wind, is one that tosses his nose as high as his ears, and does not carry handsomely. The difference between carrying in the wind, and beating upon the hand, is, that the horse who beats upon the hand, shakes his head, and resists the bridle; but he who carries in the wind, put up his head without shaking, and only sometimes beats upon the hand. The opposite to carrying in the wind, is arming and carrying low.

WIND-FLOWER, *Anemone*, in botany. See the article ANEMONE.

WIND-GALL, a name given by our farriers to a distemperature of horses. In this case there are bladders full of a corrupt jelly, which, when let out, is thick, and of the colour of the yolk of an egg. They vary in size, but are more usually small than large. Their place is about the fetloc-joint, and they grow indifferently on all four legs, and are often so painful, especially in the summer season, when the weather is hot, and the ground dry and hard, that they make the creature frequently stumble, or even fall down. The general method of cure is to open the swelling, about the length of a bean, and to press out the jelly: when this is done, they apply a mixture of the oil of bays, and the white of an egg, covering it with tow. Another method is, after the jelly is all squeezed out, to wrap round the part a wet woollen-cloth, and then applying a taylor's hot iron, this is to be rubbed over till the moisture is carried away; it is then to be doubed all over with pitch, mastich, and resin, boiled together, laying tow in plenty over all. The wind-galls that are situated near the sinews, are much the most painful of all, and soonest make the horse lame.

The general cause of wind-galls is supposed to be extreme work or exercise in hot weather; but it is to be observed, that those horses which have long joints, will be wind-galled if they work never so little. The worst wind-galls are those of the hinder legs; all the above-mentioned methods will frequently miss of success in these, and nothing but fire will cure them.

WIND-HATCH, in mining, a term used to express the place at which the ore is taken out of the mines.

WIND-SHOCK, a name given by our farmers to a distemperature to which fruit-trees, and sometimes timber-trees, are subject.

Mortimer is of opinion, that the wind shock is a sort of bruise and shiver throughout the whole substance of the tree; but that the bark being often not affected by it, it is not seen on the outside, while the inside is twisted round, and greatly injured.

It is by some supposed to be occasioned by high winds; but others attribute it to lightning. Those trees are most usually affected by it, whose boughs grow more out on one side than on the other.

The best way of preventing this in valuable trees, is to take care, in the plantation, that they are sheltered well, and to cut them frequently in a regular manner, while young. The winds not only twist trees in this manner, but they often throw them wholly down; in this case the common method is to cut up the tree for firing, or other uses; but if it be a tree that is worth preserving, and it be not broken, but only torn up by the roots, it may be proper to raise it again, by the following method:

let

let a hole be dug deep enough to receive its roots, in the place where they before were: let the straggling roots be cut off, and some of the branches, and part of the head of the tree: then let it be raised; and when the torn-up roots are replaced in the earth, in their natural situation, let them be well covered, and the hole filled up with rammed earth; the tree will, in this case, grow well, and perhaps better, than before. If nature be left to herself, and the tree be not very large, the pulling off the roots will raise it.

*Whirl-Wind.* See WHIRL-WIND.

*WINDAGE of a Gun*, the difference between the diameter of the bore, and the diameter of the ball.

*WINDLASS*, or *WINDLACE*, a machine used to raise huge weights withal, as guns, stones, anchors, &c.

It is very simple, consisting only of an axis, or roller, supported horizontally at the two ends, by two pieces of wood and a pulley: the two pieces of wood meet at top, being placed diagonally, so as to prop each other; the axis, or roller, goes through the two pieces, and turns in them. The pulley is fastened at top where the pieces join. Lastly, there are two staves or handspikes go through the roller, whereby it is turned, and the rope which comes over the pulley is wound off and on the same.

*WINDOW*, q. d. wind-door, an aperture or open place in the wall of a house, to let in the wind and light. See the article *HOUSE*.

We have various forms of windows, as, arched windows, circular windows, elliptical windows, square and flat windows, round windows, oval windows, Gothic windows, regular windows, rustic windows, and sky-lights.

The chief rules in regard to windows are, 1. That they be as few in number, and as moderate in dimensions, as may consist with other due respects; inasmuch as all openings are weakenings. 2. That they be placed at a convenient distance from the angles, or corners of the building; because that part ought not to be enfeebled, whose office is to support and fasten all the rest of the building. 3. That care be taken that the windows are all equal one with another, in their rank and order; so that those on the right hand may answer to those on the left, and those above be right over these below; for this situation of windows will not only be handsome and uniform, but also the void being upon the void, and the full upon the full, it will be a great strengthening to the whole fabric.

As to their dimensions, care is to be taken not to give them more or less light than is needful; that is, to make them no bigger, nor less, than is convenient; therefore, regard is to be had to the bigness of the rooms which are to receive the light: it is evident, that a great room needs more light, and, consequently, a greater window than a little room.

The apertures of windows, in middle-sized houses, may be four and a half, or five feet, between the jambs, and in greater buildings six and a half, or seven feet, and their height may be double their length at the least. But in high rooms, or large buildings, their height may be a third, a fourth, or half a breadth more than double their length. These are the proportions of the windows for the first story; and according to these must the upper stories be for breadth; but, as for height, they must diminish: the second story may be one-third part lower than the first, and the third one-fourth part lower than the second.

*WINE*, *Vinum*, a brisk, agreeable, spirituous, and cordial liquor, drawn from vegetable bodies and fermented. See *FERMENTATION*.

The character of a wine, according to Boerhaave, is, that the first thing it affords by distillation, be a thin, oily, inflammable fluid, called a spirit.

This distinguishes wines from another class of fermented vegetable juices, viz. vinegar, which instead of such spirit, yields, for the first thing, an acid un-inflammable matter.

All sorts of vegetables, fruits, seeds, roots, &c. afford wine; as grapes, currants, mulberries, elderberries, cherries, apples, pulse, beans, peas, turneps, radishes, and even grass itself. Hence, under the class of wines, or vinous liquors, come not only wines absolutely so called, but ale, cyder, &c. See *VINEGAR*.

*WINE*, is, in a more peculiar manner, appropriated to that which is drawn from the fruit of the vine, by stamping its grapes in a vat, or crushing and expressing the juice out of them in a press, and then fermenting them, &c.

The goodness of wine consists in its being neat, dry, fine, bright, and brisk, without any taste of the foil, of a clean steady colour, having a strength without being heady, a body without being sour, and keeping without growing hard or eager. The difference of flavour, taste, colour, and body, in wines, is, perhaps, as much owing to the different manner and time of pressing, gathering, and fermenting the grape, as to any difference of the grape itself.

In Hungary, whence tockay and some of the richest and highest-flavoured wines come, they are extremely curious in these respects: for their prime and most delicate wines, the grape is suffered to continue upon the vine, till it is half dried by the heat of the sun; and, if the sun's heat should not prove sufficient, they are dried by the gentle heat of a furnace, and then picked one by one from the stalks; the juice of this grape, when pressed out, is of a fine flavour, and sweet as sugar: this, after due fermentation, is kept for a year, and then racked from the leys, when it proves a generous, oily, rich wine, and is sold at a very high rate.

The Hungarians prepare a second sort of wine, by

by collecting together the better kind of grapes, carefully picking the fruit from the stalks, and then pressing out the juice: this is extremely sweet, and is made richer by infusing in it, after it has fermented for some days, a sufficient quantity of half-dried grapes. This wine, besides being very sweet, is oily, and of a grateful taste, and retains these qualities for a long time.

There is a third sort, made from the pure juice of this kind of grape, without any addition. This is a more brisk and lively wine, and far less sweet.

They likewise prepare a fourth sort, from grapes of different goodness mixed together; this, though not so generous, is nevertheless an excellent wine.

These Hungarian wines are remarkable for preserving their sweetness, and for the delicacy of their taste and smell; they, likewise, do not grow easily vapid, and may be kept in perfection for many years.

Wine being a liquor mostly of foreign produce, the divers names, forms, kinds, distinctions, &c. thereof, are borrowed from the countries where it is produced; the principal whereof, at this day, is France, to wines of which country, a good part of what we have to say of this noble liquor, will more immediately belong.

Wine in France is distinguished from the several degrees and steps of its preparation, into, 1. *Mere goutte*, mother drop, which is the virgin wine, or that which runs of itself out at the top of the vat wherein the grapes are laid, before the vintager enters to tread or stamp the grapes. 2. Must, sur-must, or stum, which is the wine or liquor in the vat, after the grapes have been trod or stamped. 3. Pressed wine, being that squeezed with a press out of the grapes half bruised by the treading. The husks left of the grapes are called rope, murk, or mark, by throwing water upon which, and pressing them afresh, they make a liquor for servants use, answerable to our cyderkin, and called *boisson*, which is of some use in medicine, in the cure of disorders occasioned by viscid humours.

4. Sweet wine, is that which has not yet worked nor fermented. 5. Bouru, that which has been prevented working by casting in cold water. 6. Worked wine, that which has been let work in the vat, to give it a colour. 7. Boiled wine, that which has had a boiling before it worked, and which by that means still retains its native sweetness. 8. Strained wine, that made by sleeping dry grapes in water, and letting it ferment of itself.

Wines are also distinguished with regard to their colour, into white wine, red wine, claret wine, pale wine, rose or black wine; and with regard to their country, or the soil that produces them, into French wines, Spanish wines, Rhenish wines, Hungary wines, Greek wines, Canary wines, &c. and more particularly into Port wine, Madeira wine, &c.

*Method of making, fining, &c. WINE.* In the Southern parts of France, their way is with red wines to tread or squeeze the grapes between the hands, and to let the whole stand, juice and husks, till the tincture be to their liking; after which they press it. But for white wines, they press the grapes immediately; when pressed they tun the must and stop up the vessel, only leaving the depth of a foot or more to give room for it to work. At the end of ten days they fill this space with some other proper wine, that will not provoke it to work again. This they repeat from time to time, new wine spending itself a little before it comes to perfection.

The usual method of fining down wines, so as to render them expeditiously bright, clear and fit for use, is this. Take an ounce of isinglass, beat it into thin threads with a hammer, and dissolve it, by boiling, in a pint of water; this when cold becomes a stiff jelly. Whisk up some of this jelly into a froth with a little of the wine intended to be fined, then stir it well among the rest in the cask, and bung it down tight; by this means the wine will become bright in eight or ten days.

This method, however, is found to be best suited to the white wines; for the red ones, the wine-coopers commonly use the whites of eggs beat up to a froth, and mixed in the same manner with their wines.

They fine it down also by putting the shavings of green beech into the vessel, having first taken off all the rind, and boiled them an hour in water to extract their rankness, and afterwards dried them in the sun, or in an oven. A bushel of these serve for a tun of wine: and being mashed, they serve again and again, till almost quite consumed.

For English wine the method recommended by Mortimer, is first to gather the grapes when very dry, to pick them from the stalks, then to press them, and let the juice stand twenty-four hours in a vat covered. Afterwards to draw it off from the gross lees, and then put it up in a cask, and to add a pint or quart of strong red or white port to every gallon of juice, and let the whole work, bunning it up close, and letting it stand till January; then bottle it in dry weather. Bradley chuses to have the liquor, when pressed, stand with the husks, stalks, and all in the vat, to ferment for fifteen days.

The method of converting white-wine into red, so much practised by the modern wine coopers, Dr. Shaw observes is this. Put four ounces of turnsole rags into an earthen vessel, and pour upon them a pint of boiling water; cover the vessel close, and leave it to cool; strain off the liquor, which will be of a fine deep red, inclining to purple. A small portion of this colours a large quantity of wine. This tincture might be either made in brandy, or mixed with it, or else made into a syrup, with sugar.

gar, for keeping. A common way with the wine-coopers is to infuse the rags cold in wine for a night or more, and then wring them out with their hands; but the inconveniency of this method is, that it gives the wine a disagreeable taste; or what is commonly called the taste of the rag; whence the wines thus coloured, usually pass among judges for pressed wines, which have all this taste from the canvas rags in which the lees are pressed.

The way of extracting the tincture, as here directed, is not attended with this inconvenience; but it loads the wine with water; and if made into a syrup, or mixed in brandy, it would load the wine with things not wanted, since the colour alone is required. Hence the colouring of wines has always its inconveniencies.

In those countries which do not produce the tinging grape, which affords a blood-red juice, where-with the wines of France are often stained, in defect of this, the juice of elder-berries is used, and sometimes logwood is used at Oporto.

The colour afforded by the method here proposed, gives wine the tinge of the Bourdeaux-red, not the port; whence the foreign coopers are often distressed for want of a proper colouring for red wines in bad years. This might perhaps be supplied by an extract made by boiling stick-lack in water. The skins of tinging grapes might also be used, and the matter of the turnsole procured in a solid form, not imbibed in rags.

Stahl observes, that it is a common accident, and a disease in wines, to be kept too hot; which is not easy to cure when it has been of any long continuance, otherwise it may be cured by introducing a small artificial fermentation, that new ranges the parts of the wine, or rather recovers their former texture: but the actual exposing of wine to the fire, or the sun, presently disposes it to turn eager; and the making it boiling hot, is one of the quickest ways of expediting the process of making of vinegar.

On the other hand, wine kept in a cool vault, and well secured from the external air, will preserve its texture intire in all the constituent parts, and sufficiently strong for many years, as appears not only from old wines, but other foreign fermented liquors, particularly those of China, prepared from a decoction of rice, which being well closed down in a vessel, and buried deep under ground, will continue for a long series of years, rich, generous, and good, as the histories of that country universally agree in assuring us.

The most general remedy hitherto known for all the diseases of wines, is a prudent use of tartarized spirit of wine, which not only enriches but disposes all ordinary wines to grow fine.

If either by fraud or accident a larger portion of water is mixed with wine than is proper for its consistence, and no way necessary or essential, this su-

perfluous water does not only deprave the taste, and spoil the excellence of the wine, but also renders it less durable; for humidity in general, and much more a superfluous aqueous humidity, is the primary and restless instrument of all the changes that are brought on by fermentation. It may doubtless, therefore be useful, and sometimes absolutely necessary, to take away this superfluous water from the other part which strictly and properly constitutes the wine. This has been agreed upon on all hands as a thing proper; but the manner of doing it has not been well agreed on; some have proposed the effecting it by means of heat and evaporation, others by percolation, and others by various other methods, all found unsuccessful when brought to the trial; but the way proposed by Dr. Shaw from Stahl, is the most certain and commodious; this is done by a concentration of the wine, not by means of heat, but of cold.

If any kind of wine, but particularly such as has never been adulterated, be in a sufficient quantity, as that of a gallon or more, exposed to a sufficient degree of cold in frosty weather, or be put into any place where ice continues all the year, as in our ice-houses, and there suffered to freeze, the superfluous water that was originally contained in the wine, will be frozen into ice, and will leave the proper and truly essential part of the wine unfrozen, unless the degree of cold should be very intense, or the wine but weak and poor. This is the principle on which Stahl founds his whole system of condensing wines by cold. When the frost is moderate, the experiment has no difficulty, because not above a third or fourth part of the superfluous water will be froze in a whole night; but if the cold be very intense, the best way is, at the end of a few hours, when a tolerable quantity of ice is formed, to pour out the remaining fluid liquor, and set it in another vessel to freeze again by itself.

If the vessel, that thus by degrees receives the several parcels of the condensed wine, be suffered to stand in the cold freezing place, where the operation is performed, the quantity lying thin in the pouring out, or otherwise, will be very apt to freeze anew; and if it be set in a warm place, some of this aqueous part thaws again, and so weakens the rest. The condensed wine, therefore, should be emptied in some place of a moderate degree as to cold or heat, where neither the ice may dissolve nor the vinous substance mixed among it be congealed. But the best expedient of all is to perform the operation with a large quantity of wine, or that of several gallons, where the utmost exactness, or the danger of a trifling waste, need not be regarded.

By this method, when properly performed, there first freezes about one third part of the whole liquor; and this is properly the more purely aqueous part of it, inasmuch that when all the vinous fluid is poured off, to be again exposed to a concentration, the ice

remaining behind, from this first freezing, being set to thaw in a warm place, dissolves into a pure and tasteless water. The frozen part, or ice, consists only of the watery part of the wine, and may be thrown away, and the liquid part retains all the strength, and is to be preserved. This will never grow sour, musty, or mouldy afterwards, and may at any time be reduced to wine of the common kind again, by adding to it as much water as will make it up to the quantity that it was before.

Wines in general may by this method be reduced to any degree of vinosity or perfection.

The benefit and advantage of this method of congelation, if reduced to practice in the large way, in the wine countries, must be evident to every body. Concentrated wines, in this manner, might be sent into foreign countries, instead of wine and water, which is usually now sent; the wines they export being loaded, and in danger of being spoiled, by three or four times their own quantity of unnecessary, superfluous, and prejudicial water.

An easy method of recovering pricked wines, may be learned from the following experiment: take a bottle of red-port that is pricked, add to it half an ounce of tartarized spirit of wine, shake the liquor well together, and set it by for a few days, and it will be found very remarkably altered for the better.

This experiment depends upon the useful doctrine of acids and alkalies. All perfect wines have naturally some acidity, and when this acidity prevails too much, the wine is said to be pricked; which is truly a state of the wine tending to vinegar: but the introduction of a fine alkaline salt, such as that of tartar, imbibed by spirit of wine, has a direct power of taking off the acidity; and the spirit of wine also contributes to this, as a great preservative in general of wines. If this operation be dexterously performed, pricked wines may be absolutely recovered by it, and remain saleable for some time: and the same method may be used to malt liquors just turned sour.

The age of wine is properly reckoned by leaves; thus they say wine of two, four, or six leaves, to signify wine of two, four, or six years old; taking each new leaf put forth by the vine, since the wine was made, for a year.

WINE is also a denomination applied in medicine and pharmacy to divers mixtures and compositions wherein the juice of the grape is a principal ingredient.

With regard to the medical uses of wines, it is observed, that among the great variety of wines in common use among us, five are employed in the shops as menstrua for medicinal simples: that is, the vinum album Hispanicum, or mountain wine; the vinum album Gallicum, or French white wine; the Canary wine, or sack; the Rhenish wine; and the red port.

The effects of these liquors on the human body, are to cheer the spirits, warm the habit, promote perspiration, render the vessels full and turgid, raise the pulse, and quicken the circulation. The effects of the full-bodied wines are much more durable than those of the thinner; all sweet wines, as Canary, abound with a glutinous, nutritious substance, whilst the others are not nutritive, or only accidentally so, by strengthening the organs employed in digestion. Sweet wines, in general, do not pass off freely by urine; and they heat the constitution more than an equal quantity of any other, though containing full as much spirit; red port, and most of the red wines, have an astringent quality, by which they strengthen the tone of the stomach, and thus prove serviceable for restraining immoderate secretions; those which are of an acid nature, as rhenish, pass freely by the kidneys, and gently loosen the belly. It is supposed that these last exasperate and occasion gouty calculous disorders, and that new wines of every kind have this effect.

WINE-SPIRIT, a term used by our distillers, and which they seem to mean the same thing with the phrase of spirit of wine; but they are taken in very different senses in the trade.

Spirit of wine is the name given to the common malt-spirit, when reduced to an alcohol, or totally inflammable state; but the phrase wine-spirit is used to express a very clean and fine spirit, of the ordinary proof strength, and made in England from wines of foreign growth.

The way of producing it is by simple distillation, and it is never rectified any higher than common bubble proof. The several wines of different natures, yield very different proportions of spirit; but, in general, the strongest yield one-fourth, the weakest in spirits one-eighth part of proof-spirit; that is, they contain from a sixteenth to an eighth part of their quantity of pure alcohol.

Wines that are a little sour, serve not at all the worse for the purposes of the distiller, they rather give a greater vinosity to the produce. This vinosity is a thing of great use in the wine-spirit, whose principal use is to mix with another that is tartarized, or with a malt-spirit, rendered alkaline by the common method of rectification. All the wine-spirits made in England, even those from the French wines, appear very greatly different from the common French brandy; and this has given our distillers a notion that there is some secret art practised in France, for the giving the agreeable flavour to that spirit; but this is without foundation.

WING, *Ala*, that part of a bird, insect, &c. whereby it is enabled to fly.

Willoughby observes, that all birds whatsoever have wings, or rudiments of wings, which answer to the fore legs in quadrupeds. Among land-fowl he observes, that the ostrich, cassowary, and dodo; and

and among water-fowl, the penguin, have wings altogether useless and unfit for flight.

Insects, indeed, have wings, and so have bats, but of a different kind from those of birds; the former being membranaceous, and the latter cutaneous: birds only have wings made up of feathers. All birds, towards the extremity of their wings, have a certain finger-like appendix, which is commonly called the secondary or bastard-wing. It is made up of four or five small feathers. Besides this under the wing, or on the inside of the wing, some birds, especially water-fowl, have a row of feathers growing, called interior bastard wing, which in most birds is of a white colour.

Reumur observes, that wings among the fly-class, afford several subordinate distinctions of the genera of those animals, under the ancient general classes. Several species of flies, while they are in a state of rest, or only walking, shew several regularly distinct manners of carrying their wings. The much greater number, however, carry them in a parallel or plain position. Among those who carry them thus, some have them in form of a sort of oars, their direction being perpendicular to the length of the body, which is not at all covered by them. Others carry their wings in this manner, so as that they cover a part of the body, without at all covering one another. The wings of others cross one another on the body of the creature, and the degrees in which they cover one another, give occasion to several other sub-distinctions; for some of them over-hang on each side the body of the animal, while others cross one another, in such a manner, as not to cover the body of the fly entirely, but leave a rim of it visible and uncovered on each side of them.

Some of the flies bred of water-worms, have their wings in this manner. Others have their wings thus disposed, but crossing one another only in a part of their surface, and that at their extremities; so that though they there cover the body of the fly, they leave a portion of the anterior part of the body naked. See the article *FLY*.

The beautiful wings of butterflies are distinguished from those of the fly-kind, by their not being thin and transparent, like them, but thicker and opaque. This opacity in them is only owing to the dust which comes off them, and sticks to the fingers in handling them; and it is also to this dust that they owe all their beautiful variety of colours. The earlier naturalists, for this reason, distinguished these insects by the appellation of such as had farinaceous wings.

The wings of gnats are of a very curious structure, and well worthy the use of the microscope, to see them distinctly. It is well known, that on touching the wings of butterflies, a coloured powder is left on the finger, which, though to the

naked eye it appears a mere shapeless dust, yet when examined by the microscope, it is found to be very regularly figured beautiful bodies, in form of feathers and scales: these are of various figures, and all of them very elegant. The generality of flies have nothing of this kind; but the close examination of the wings of the gnat will shew, that they are not wholly destitute of them: they are much more sparingly bestowed, indeed, upon the gnat than on the butterfly; but then they are arranged with greater regularity.

WINGS, in heraldry, are borne sometimes single, sometimes in pairs; in which case they are called conjoined. When the points are downward, they are said to be inverted; when up, elevated.

WING, in botany, the angle formed between the stem and the leaves, or pedicles of the leaves of a plant.

WINGS, in military affairs, are the two flanks or extremes of an army, ranged in form of a battle; being the right and left sides thereof.

WINGS, in fortification, denote the longer sides of horn-works, crown-works, tenailles, and the like out-works; including the ramparts and parapets, with which they are bounded on the right and left from their gorge to their front.

WINGED-LEAVES, in botany, are those which are composed of several folioli, or little leaves, ranged on each side the common footstalk like wings; but as these are disposed in different forms, so they have different appellations. See the articles *PINNATE*.

WINGED-SEEDS, are those which are furnished with down or hairs, by the help of which they are buoyed up in the air, and carried a considerable distance; such are those of the dandelion, sowthistle, &c.

WINNOW, signifies to fan or separate corn from the chaff by the wind.

WINTER, one of the four seasons or quarters of the year.

Winter commences on the day when the sun's distance from the zenith of the place is greatest, and ends on the day when its distance is at a mean between the greatest and least.

Notwithstanding the coldness of the season, it is proved by astronomers, that the sun is really nearer the earth in winter than in summer.

Under the equator, the winter as well as other seasons, return twice every year; but all other places have only one winter in the year, which in the northern hemisphere begins when the sun is in the tropic of Capricorn, and in the southern hemisphere when in the tropic of Cancer; so that all places in the same hemisphere have their winter at the same time.

WINTER, among printers, that part of the printing press serving to sustain the carriage.

**WINTER'S BARK**, *Cortex Winteranus*, in botany, a name given to the bark of the white or wild cinnamon tree.

The winter's bark is a thick and firm bark, tho' we have a different thing sometimes under its name: it comes to us rolled up in the manner of the common cinnamon, into a kind of tubes or pipes; but they are usually thicker, and always shorter than the fine tubes of cinnamon. It is externally of a greyish colour, and of a reddish brown within; it is properly indeed a double bark, the outer and inner of the same tree, not the inner bark alone, separated from the other, as the cinnamon and cassia are. The outer rind is of an uneven surface and of a loose texture, very brittle, and easily powdered. The inner bark, which has the principal virtue, is hard, and of a dusky reddish brown. The outer one is often cracked and open in several places, the inner one never in any. It is of an extremely fragrant and aromatic smell, and of a sharp, pungent, and aromatic taste, much hotter than cinnamon in the mouth, and leaving a more lasting flavour on it.

It is to be chosen in pieces not too large, with the inner or brown part sound and firm, and of a very sharp taste. It is apt to be worm eaten; but in that case it is wholly to be rejected, as having lost the far greater part of its virtue.

The cortex Winteranus was wholly unknown to the ancients; the discovery of it among us is owing to captain Winter, who, in the year 1567, going as far as the Straights of Magellan with Sir Francis Drake, found this bark on that coast, and bringing a large quantity of it with him in his return to England, it became used in medicine, and was ever after called by his name. It is not, however, peculiar to the place he found it in, but is frequent in many parts of America.

The virtues of this bark were discovered by the English sailors on board captain Winter's ship; they first used it by way of spice to their foods, and afterwards for the scurvy. It is also good in palsies and rheumatisms; and a decoction of the leaves is good, by way of fomentation, for the parts externally affected by the scurvy. The English sailors made it famous for its virtues against the poison of a certain fish, common about the Magellanic sea, which they called the sea-lion: they eat the flesh of this fish, and fell into many illnesses by it; among which was one attended with a peeling off the skin of their whole bodies, not without excessive pain; this they remedied by the cortex Winteranus: but by the accounts we have of the effects of eating this fish, as it is called, they were rather symptoms of an inveterate scurvy, and, therefore, it is no wonder this bark did them great service.

**WINTER-QUARTERS.** See the article **QUARTERS**.

**WINTER-RIG**, among husbandmen, signifies to fallow or till the land in winter.

**WINTER-SOLSTICE.** See the article **SOLSTICE**.

**WINTERANA**, in botany, a genus of plants, whose flower consists of five oblong sessile petals, with a conic, concave, pitcher-shaped nectarium: the stamina hath no filaments, but consists of sixteen linear antheræ: the fruit is a roundish berry with three cells, each containing two heart-shaped seeds.

**WIRE**, a piece of metal drawn through the hole of an iron into a thread, of a fineness answerable to the hole it passed through.

Wires are frequently drawn so fine, as to be wrought along with other threads of silk, wool, flax, &c.

The metals most commonly drawn into wire, are gold, silver, copper, and iron. Gold wire is made of cylindrical ingots of silver, covered over with a skin of gold, and thus drawn successively through a vast number of holes, each smaller and smaller; till at last it is brought to a fineness exceeding that of a hair. That admirable ductility which makes one of the distinguishing characters of gold, is no where more conspicuous, than in this gilt wire. A cylinder of forty-eight ounces of silver, covered with a coat of gold, only weighing one ounce, as Dr. Halley informs us, is usually drawn into a wire, two yards of which weigh no more than one grain; whence ninety-eight yards of the wire weigh no more than forty-nine grains, and one single grain of gold covers the ninety-eight yards; so that the thousandth part of a grain is above one-eighth of an inch long. The same author, computing the thickness of the skin of gold, found it to be  $\frac{1}{1343560}$  part of an inch. Yet so perfectly does it cover the silver, that even a microscope does not discover any appearance of the silver underneath. M. Rohault likewise observes, that a like cylinder of silver, covered with gold, two feet eight inches long, and two inches nine lines in circumference, is drawn into a wire 307200 feet long i. e. into 115200 times its former length. Mr. Boyle relates, that eight grains of gold, covering a cylinder of silver, is commonly drawn into a wire 13000 feet long. See the articles **GOLD** and **DUCTILITY**.

Silver-wire is the same with gold-wire, except that the latter is gilt, or covered with gold, and the other is not.

There are also counterfeit gold and silver-wires; the first made of a cylinder of copper, silvered over, and then covered with gold; and the second of a like cylinder of copper, silvered over, and drawn through the iron, after the same manner as gold and silver-wire.

Brass-wire is drawn after the same manner as the former. Of this there are divers sizes, suited to the different

different kinds of works. The finest is used for the strings of musical instruments, as spinets, harpsichords, manichords, &c. See the article SPINET, &c.

The pin-makers, likewise, use vast quantities of brass-wire, to make their pins of. Iron-wire is drawn of various sizes, from half an inch to one-tenth of an inch diameter.

The first iron that runs from the stone, when melting, being the softest and toughest, is preserved to make wire of. Iron-wire is made from small bars of iron, called *esseom-iron*, which are first drawn out to a greater length, and to about the thickness of one's little finger, at a furnace, with a hammer gently moved by water. These thinner pieces are bored round, and put into a furnace to aneal for twelve hours. A pretty strong fire is used for this operation. After this they are laid under water for three or four months, the longer the better; then they are delivered to the workmen, called *rippers*, who draw them into wires through two or three holes. After this they aneal them again for six hours, and water them a second time for about a week, and they are then delivered again to the *rippers*, who draw them into wire of the thickness of a large packthread. They are then anealed a third time, and then watered for a week longer, and delivered to the small wire-drawers, called *over-house-men*.

In the mill where this work is performed, there are several barrels hooped with iron, which have two hoops on their upper sides, on each whereof hang two links which stand across, and are fastened to the two ends of the tongs, which catch hold of the wire, and draw it through the hole. The axis on which the barrel moves does not run through the center, but is placed on one side, which is that on which the hooks are placed; and underneath there is fastened to the barrel a spoke of wood, which they call a *swingle*, which is drawn back a good way by the cogs in the axis of the wheel, and draws back the barrel, which falls to again by its own weight. The tongs hanging on the hooks of the barrel, are by the workmen fastened to the end of the wire, and by the force of the wheel, the hooks being pulled back, draw the wire through the holes. The plate in which the holes are, is iron on the outside, and steel on the inside; and the wire is anointed with train-oil, to make it run the easier.

**WISDOM**, *sapientia*, usually denotes a higher and more refined notion of things immediately presented to the mind, as it were, by intuition, without the assistance of ratiocination. See **UNDERSTANDING**, **REASON**, **KNOWLEDGE**, &c.

In this sense wisdom may be said to be a faculty of the mind, or at least a modification and habit thereof. See **FACULTY**, **MODIFICATION**, **HABIT**, &c.

Sometimes the word is more immediately used, in a moral sense, for what we call prudence, or dis-

cretion, which consists in the soundness of the judgment, and a conduct answerable thereto.

**WIT**, a faculty of the mind, consisting, according to Mr. Locke, in the assembling and putting together of those ideas, with quickness and variety, in which any resemblance or congruity can be found, in order to form pleasant pictures and agreeable visions to the fancy. This faculty, the same author observes, is just the contrary of judgment, which consists in the separating carefully from one another, such ideas wherein can be found the least difference, thereby to avoid being misled by similitude and affinity, to take one thing for another. It is the metaphor and allusion, wherein, for the most part, lies the entertainment and pleasantry of wit, which strikes so lively on the fancy, and is therefore so acceptable to all people, because its beauty appears at first sight, and there is required no labour of thought to examine what truth or reason there is in it. The mind, without looking any farther, rests satisfied with the agreeableness of the picture, and the gaiety of the imagination; and it is a kind of affront to go about to examine it by the severe rules of truth or reason.

**WITCHCRAFT**, a kind of forcery, especially in women, in which it is ridiculously supposed that an old woman, by entering into a contract with the devil, is enabled, in many instances, to change the course of nature; to raise winds; perform actions that require more than human strength; and to afflict those who offend them with the sharpest pains, &c.

In the times of ignorance and superstition, many severe laws were made against witches, by which great numbers of innocent persons, distressed with poverty and age, were brought to a violent death; but these are now happily repealed.

**WITENA-MOT**, or **WITENA-GEMOT**, among our Saxon ancestors, was a term which literally signified the assembly of the wise men, and was applied to the great council of the nation, of latter days called the parliament.

**WITHERNAM**, in law, a writ that lies where a distress is driven out of the county, and the sheriff cannot make deliverance to the party distrained; in that case this writ is directed to the sheriff, commanding him to take as many of the beasts, or goods, of the party into his keeping till he make deliverance of the first distress.

**WITHERS** of a horse, the juncture of the shoulder-bones at the bottom of the neck and main, towards the upper part of the shoulder.

**WITNESS**, in law, a person who gives evidence in any cause, and is sworn to speak the truth, the whole truth, and nothing but the truth.

**WOAD**, *isatis*, in botany. See **ISATIS**.  
This is a drug used by the dyers to give a blue colour. It arises from seed sown annually in the spring, which puts forth leaves resembling those of rib-wort plaitain.

**plantain.** These plants have usually three, four, or five crops of leaves every year, of which the first is the best, and the rest in their order. When the leaves are ripe, they gather them, and carry them to a woad mill to grind them small; after which they are laid eight or ten days on heaps, and are at length made into a kind of balls, which are laid in the shade on hurdles to dry. This done, they break or grind them to powder; which is then spread on a floor and water'd. Here they let it smoke and heat, till by torrifizing it every day it becomes quite dry.

A woad blue is a very deep blue, almost black; and is the base of so many sorts of colours, that the dyers have a scale by which they compose the several casts or degrees of woad, from the brightest to the deepest.

**WOLD**, signifies a plain down, or open campaign ground, hilly and void of wood.

**WOLD**, or **WELD**, among dyers. See the article **WELD**.

**WOLF**, *lupus*, in zoology, a very large and fierce animal, being equal to the biggest mastiff in size, and having much of the general appearance of that creature; the head is large and fleshy; the eyes are large and prominent, and their iris hazel: the ears are short, patulous, and erect: the teeth are very large, and the animal has a way of shewing them in a frightful manner, by grinning: the neck is robust and thick: the body is large, and the back broad: the legs are very robust: the tail is long and bushy: the natural colour is black, but there are some tawny; and in some places they are in winter perfectly white. The wolf is a very mischievous creature, destroying cattle; and in hard winters attacking houses and villages in whole troops.

**WOLF'S BANE**, in botany, the English name for the *aconitum*. See the article **ACONITE**.

**WOLVES TEETH**, of an horse, are over-grown grinders, the points of which being higher than the rest, prick his tongue and gums in feeding, so as to hinder his chewing. They are seldom met with in any besides young horses; but if they be not daily worn by chewing, they will grow up even to pierce the roof of the mouth.

**WOMAN**, *fœmina*, in zoology, the female of man. See the article **MAN**.

**WOMB**, *uterus*. See **UTERUS**.

**WOOD**, *lignum*, a solid substance, whereof the trunks and branches of trees consist.

The wood is all that part of a tree included between the bark and the pith. See the article **BARK**.

Dr. Grew, in his *Anatomy of Plants*, has discovered, by means of the microscope, that what we call wood in a vegetable, notwithstanding all its solidity, is only an assemblage of infinite minute canals, or hollow fibres, some of which rise from the root upwards, and are disposed in form of a circle; and the others, which he calls insertions, tend horizontally from the surface to the center; so that they

cross each other, and are interwoven like the threads of a weaver's web. See **VEGETATION**, **SAP**, &c.

Notwithstanding this, Mr. Buffon observes, that the organization of wood is yet unknown in all its parts; and that though the world is greatly indebted to the observations of Grew, Malpighi, and Hales, yet when he entered on the subject, he found there was much more unknown than known; and determined to observe, from its first state, the growth of trees, and the formation of their woody part. For this ingenious author's exposition of the texture, &c. of wood, and thence his calculation of the force and strength of timber used in building, we must refer the reader to his paper upon that subject, as published in the *Memoirs Acad. Par.* for the year 1740, and to what has been said under the article **TIMBER**.

Mortimer observes, that all kinds of wood are to be preserved from the worm, and from many other occasions of decay, by oily substances, particularly the essential oils of vegetables. Oil of spike is excellent; and oil of juniper, turpentine, or any other of this kind, will serve the purpose; these will preserve tables, instruments, &c. from being eaten to pieces by these vermin; and linseed-oil will serve, in many cases, to the same purpose; probably nut-oil will do also, and this is a sweeter oil, and a better varnish for wood.

Some of the West-Indian trees afford a sort of timber, which, if it would answer in point of size, would have great advantages over any of the European wood in ship-building for the merchant-service, no worm ever touching this timber. The acajou, or tree which produces the cashew-nut, is of this kind; and there is a tree of Jamaica, known by the name of the white-wood, which has exactly the same property; and so have many other of these trees.

To season wood expeditiously for sea-service, Mr. Boyle observes, that it has been usual to bake it in ovens.

**Cutting in Wood**, is used for various purposes; as for initial and figured letters, head and tail pieces of books, and even for schemes, mathematical and other figures, to save the expence of engraving on copper; also for prints, and stamps for papers, calicoes, linens, &c.

The invention of cutting in wood, as well as that in copper, is ascribed to a gold-smith of Florence; but Albert Durer and Lucas brought both these arts to perfection.

About 200 years ago, the art of cutting in wood was carried to a very great pitch, and might even vie, for beauty and justness, with that of engraving on copper: at present it is much neglected, the application of artists being wholly employed on copper, as the more easy and promising province: not but that wooden cuts have the advantage of those in copper in many respects, chiefly for figures and devices in books; as being printed at the same time

and in the same press with the letters: whereas for the other, there is required a particular and separate impression.

The cutters in wood begin with preparing a plank, or block, of the size and thickness required, and very even and smooth on the side to be cut: for this, they usually take pear-tree, or box; but the latter is best, as being closest, and least liable to be worm eaten. On this block they draw the design with a pen or pencil, exactly as they would have it printed; or they fasten the design drawn on paper upon the block with paste and a little vinegar, the strokes or lines turned towards the wood. As soon as the paper is dry, they wash it gently with a sponge dipped in water, and then take it off by little and little, rubbing it first with the tip of the finger, till nothing is left on the block but the strokes of ink that form the design, which mark out what part of the block is to be spared or left standing. The rest they cut off very carefully with the points of very sharp knives, chisels, or gravers, according to the bigness or delicacy of the work.

WOOD, *Silva*, in geography, a multitude of trees extended over a large continued tract of land, and propagated without culture. The generality of woods only consist of trees of one kind.

The ancient Saxons had such a veneration for woods, that they made them sanctuaries.

The burning of woods, or under-wood, is declared to be felony; also those persons that maliciously cut or spoil timber-trees, fruit-trees, &c. shall be sent to the house of correction, there to be kept three months, and whipt once a month.

WOODBIND, the English name for a species of *Joncra*. See the article *LONICERA*.

WOODCOCK, *Scolopax*, in ornithology. See the article *SCOLOPAX*.

WOOD and WOOD, in the sea language, is when two pieces of timber are so set into each other, that the wood of the one joins close to the other.

WOOD-LOUSE, in zoology, a name given to several species of oniscus. The common wood-louse, or millepes, is the oniscus with a blunt forked tail. See *ONISCUS* and *MILLEPES*.

WOOD-PECKER, *Picus*, in ornithology, a genus of birds with the beak straight, of a polyhedral or many-sided figure, and with its point formed in the manner of a wedge; the tongue is rounded and very long, it resembles in form a worm, or some other such insect; the toes, in all but one species, stand two before and two behind, as in the parrot. Of this genus there are several species.

WOOD-SORREL, *Oxalis*, in botany. See the article *OXALIS*.

WOODWARD, an officer of the forest, whose function it is to look after the woods, and observe any offences either in vert or in venison, committed within his charge, and to prevent the same; and in

case any deer are found killed, or hurt, to inform the verderer thereof, and to present them at the next court of the forest. See *FOREST*.

WOOF, among manufacturers, the threads which the weavers shoot across with an instrument called a shuttle.

The woof is of different matter, according to the piece to be wrought. In taffety, both woof and warp are silk. In mohairs, the woof is usually wool and the warp silk. In satins, the warp is frequent-flax, and the woof silk. See the articles *WARP* and *WEAVING*.

WOOL, the covering of sheep. Each fleece consists of wool of several qualities and degrees of fineness, which the dealers therein take care to separate.

The English and French usually separate each fleece into three principal sorts, viz. 1. Mother-wool, which is that of the back and neck. 2. The wool of the tails and legs. 3. That of the breast and under the belly. The wool most esteemed is the English, chiefly that about Leominster, Cotswold, and the Isle of Wight; the Spanish, principally that about Segovia; and the French, about Berry.

The fineness and plenty of our wool is owing, in a great measure, to the short sweet grass in many of our pastures and downs; though the advantage of our sheeps feeding on this grass all the year, without being obliged to be shut up under cover during the winter, or to secure them from wolves at other times, contributes not a little to it.

Antiently, the principal commerce of the nation consisted in wool unmanufactured; which foreigners, especially the French, Dutch, and Flemish, bought of us; insomuch, that the customs paid on wool exported, in the reign of Edward III. amounted, at 50s. the pack, to 250,000*l.* per annum: an immense sum in those days!

But as wool is now accounted a staple commodity, the employment of an infinite number of people at home, and our most beneficial trade abroad, depending upon it, very severe laws have been made to prevent its being exported, and persons that export wool beyond the seas, are liable to a forfeiture of the ships or vessels in which it is found, with treble the value, and the persons aiding and assisting in it, shall suffer three years imprisonment.

It is also enacted, that no sheep shall be carried on board any ship with intent to be exported, upon forfeiture of 20*s.* for every sheep; that the owners knowing thereof, are to forfeit their interest therein; that if they be aliens, or natural born subjects not inhabiting this kingdom, such ships shall be wholly forfeited; that the masters or mariners knowing thereof, and assisting therein, are to forfeit all their goods and chattels, and to suffer three months imprisonment; and that the exporter, besides

sides other penalties, shall be rendered incapable of suing for any debt, &c.

As to the importation of wool, Irish wool, combed or uncombed, Spanish or Polish wool, may be imported duty free.

WOOL, is also used for the soft hair growing on several wild beasts, the skins of which are distinguished by the name of furs. See FUR.

Cotton-WOOL. See the article COTTON.

WOOL-STAPLE, denotes a city or town where wool used to be sold. See the article STAPLE.

WOOL-WINDERS, are persons employed in winding up fleeces of wool into bundles to be packed and sold by weight. Those are sworn to do it duly between the owner and the merchant.

WOOLLEN MANUFACTORY, includes the several sorts of commodities into which wool is wrought, as broad cloth, long and short kerseys, bays, ferges, flannel, perpetuanas, lays, stuffs, frize, pennistones, stockings, caps, rugs, &c. See the article CLOTH, &c.

WOOLSTED. See the article WORSTED.

WORD, in language, an articulate sound designed to represent some idea.

The port-royalists define words to be distinct articulate sounds, agreed on by mankind to convey their thoughts and sentiments by.

Word, in writing, is defined to be an assemblage of several letters forming one or more syllables, and expressing the name, quality, or manner of a thing.

Etymology and syntax being the two parts of grammar conversant about words, the first of these explains the nature and propriety of words, and the other treats of the right composition of words in discourse.

The most remarkable thing in the pronouncing of words, is the accent, or the elevation of the voice, on some particular syllable of the word, which elevation is necessarily followed by a depression of the voice.

Grammarians generally divide words into eight classes, called parts of speech.

Words are again divided into primitives and derivatives, simple and compound, synonymous and equivocal.

With regard to their syllables, words are farther divided into monosyllables and polysyllables.

The grammatical figures of words which occasion changes in the form &c. thereof are prosthesis, aphæresis, syncope, epenthesis, apodope, paragoge, crasis, diæresis, metathesis, and antithesis.

The use of words, we have observed, is to serve as sensible signs of our ideas; and the ideas they stand in the mind of the person that speaks, are their proper significations.

Simple and primitive words have no natural connection with the things they signify, whence there is no rationale to be given of them; it is by mere

arbitrary institution and agreement of men, that they come to signify any thing. Certain words have no natural propriety or aptitude to express certain thoughts more than others; were that the case there could have been but one language. But in derivative, and compound words the case is somewhat different. In the forming of these, we see regard is had to agreement, relation, and analogy; thus most words that have the same ending, have one common and general way of denoting or signifying things; and those compounded with the same prepositions, have a similar manner of expressing and signifying similar ideas, in all the learned languages where they occur.

For the perfection of language, it is not enough, Mr. Locke observes, that sounds can be made signs of ideas, unless these can be made use of so as to comprehend several particular things; for the multiplication of words would have perplexed their use, had every particular thing needed a distinct name to be signified by. To remedy this inconvenience, language had a further improvement in the use of general terms, whereby one word was made to mark a multitude of particular existances; which advantageous use of sounds was obtained by the difference of the ideas they were made signs of, those names becoming general which are made to stand for general ideas, and those remaining particular, where the ideas they are used for are particular.

It is observable, that the words which stand for actions and notions, quite removed from sense, are borrowed from sensible ideas; as to imagine, apprehend, comprehend, understand, adhere, conceive, instil, disgust, disturbance, tranquility, &c. which are all taken from the operations of things sensible, and applied to modes of thinking. Spirit, in its original signification, is no more than breath; angel, a messenger. By which we may guess what kind of notions they were, and whence derived, which filled the minds of the first beginners of languages; and how nature, even in the naming of things unawares, suggested to men the originals of all their knowledge: whilst to give names that might make known to others any operations they felt in themselves, or any other ideas that came not under their senses, they were forced to borrow words from the ordinary and known ideas of sensation.

The ends of language, in our discourse with others, are chiefly three; first, to make our thoughts or ideas known one to another. This we fail in, 1. when we use names without clear and distinct ideas in our mind. 2. When we apply received names to ideas, to which the common use of that language doth not apply them. 3. When we apply them unsteadily, making them stand now for one, and anon for another idea. Secondly, to make known our thoughts with as much ease and quickness, as possible. This men fail in when they have complex ideas, without having distinct names for them, which

which may happen either through the defect of a language which has none, or the fault of the man who has not yet learned them. Thirdly, to convey the knowledge of things. This cannot be done but when our ideas agree to the reality of things. He that has names without ideas, wants meaning in his words, and speaks only empty sounds. He that has complex ideas without names for them, wants dispatch in his expression. He that uses his words loosely, and unsteadily, will either not be minded or not understood. He that applies names to ideas, different from the common use, wants propriety in his language, and speaks gibberish; and he that has ideas of substances disagreeing with the real existence of things, so far, wants the materials of true knowledge.

WORD, or *Watch*. WORD, in an army or garrison, is some peculiar word or sentence, by which the soldiers know and distinguish one another in the night, &c. and by which spies and designing persons are discovered. It is used also to prevent surprises. The word is given out in an army every night to the lieutenant, or major general of the day, who gives it to the majors of the brigades, and they to the adjutants; who give it first to the field officers, afterwards to a serjeant of each company, who carry it to the subalterns. In garrisons it is given after the gate is shut to the town major, who gives it to the adjutants and they to the serjeants.

WORKS, *Opera*, in fortification, the several dikes, trenches, ditches, &c. made round a place or army, or the like, to fortify and defend it.

WORLD, *Mundus*, the assemblage of parts which compose the universe. See the article *UNIVERSE*.

The duration of the world is a thing which has been greatly disputed. Plato after Ocellus Lucanus, held it to be eternal, and to have flowed from God as rays flow from the sun. Aristotle was much of the same mind; he asserts that the world was not generated so as to begin to be a world, which before was none: he lays down a pre-existing and eternal matter as a principle, and thence argues the world eternal. His arguments amount to this, that it is impossible an eternal agent, having an eternal passive subject, should continue long without action. His opinion was generally followed, as seeming to be the fittest to end the dispute among so many sects about the first cause. See the articles *MATTER*, *CAUSE*, and *PERIPATETIC Philosophy*.

Epicurus, however, though he makes matter eternal, yet shews the world to be but a new thing formed out of a fortuitous concurrence of atoms. See the articles *ATOMICAL* and *EPICUREAN*.

Some of the modern philosophers refute the imaginary eternity of the world by this argument, that if it be *ab eterno*, there must have been a generation of individuals in a continual succession from all eternity, since no cause can be assigned why they

should not be generated, viz. one from another. Therefore to consider the origin of things, and the series of causes, we must go back in infinitum, i. e. there must have been an infinite number of men and other individuals already generated, which subverts the very notion of number. And if the cause which now generates has been produced by an infinite series of causes, how shall an infinite series be finite? Dr. Halley suggests a new method of finding the age of the world from the degree of the saltiness of the ocean. See *SEA*.

WORMS, in the Linnæan system of nature, a class of insects of the order of the apteria, and of the class of the anarthra.

The distinguishing character of this class is, that they have the muscles of their body affixed to a solid basis. The several species of worms are very numerous; as the chætia, or the hair worm, called also the guinea worm; the ascaris, the lumbricus or the earth worm; and sea-worm; the tænia, or tape worm; the sicyania or gourd worm; the iulus or gally-worm, &c.

WORMS, in husbandry, are very prejudicial to cornfields, eating up the roots of the young corn, and destroying great quantities of the crop. Sea-salt is the best of all things for destroying them. Sea-water is proper to sprinkle on the land, where it can be had; where the salt springs are, their water do; and were neither are at hand, a little common or bay-salt does as well. Soot will destroy them in some lands, but is not to be depended upon, for it does not always succeed. Some farmers strew on their lands a mixture of chalk and lime; and others trust wholly to their winter-fallowing to do it, if this is done in a wet season, when they come up to the surface of the ground, and some nails with sharp heads be driven into the bottom of the plough. If they are troublesome in gardens, the refuse brine of salted meat will serve the purpose, or some walnut leaves steeped in a cistern of water for a fortnight or three weeks, will give it such a bitterness that it will be a certain poison to them. A decoction of wood ashes, sprinkled on the ground, will answer the same purpose; and any particular plant may be secured both from worms and snails by strewing a mixture of lime and ashes about its roots. It is a general caution among the farmers to sow their corn as shallow as they can, where the field is very subject to worms.

WORMS, in medicine, a disease arising from some of these reptiles being ingendered in the body, particularly in the stomach and intestines.

When children begin to use crude aliments, summer fruits, flesh, cheese, and other things of the like kind, they are frequently troubled with worms, occasioned by the eggs of insects, which either float in the air, or live on the earth, and which being casually swallowed, are not digestible by their tender stomachs. For these, the intestinal or gastric pituit,

pituit, afford a nest in which they reside, are nourished, bred, and increase in bulk. Hence they are not so common in adults, except in the dull and sluggish, and in the leuco-phlegmatic.

There are three species of worms, most frequent in the human body; the lumbrici, the ascarides, and the tænia. The lumbrici are found in the ilion, and are thus called, because they are generally broad and long, and roll themselves up in a strange manner. The ascarides have their seat chiefly in the gross intestines, and are more plentiful in the rectum; they are round and small, and are thrown out in large quantities. The broad worm called tænia, is like a swathe, commonly two ells long, but sometimes much longer, and divided through the whole length with cross joints or knots. This is said to be always single; and lies variously convoluted, being sometimes as long as all the guts, and sometimes even vastly exceeding that length. Heister observes, that their are other kinds of insects, or worms, generated in a human body, which physicians have not placed in any particular class, but have looked upon them as uncommon productions.

Worms, by their irritation, create nausea, vomitings, looseness, faintings; a slender, deficient, intermitting pulse; itching of the nose, and epileptic fits. By the consumption of the chyle, they produce hunger, paleness, weakness, and costiveness; whence arises a tumour of the abdomen, eructations, and rumbling of the intestines.

A child may be known to have the worms from his age; cold temperament, paleness of the countenance, livid eye-lids, hollow eyes, itching of the nose, voracity, startings, and grinding the teeth in sleep; and more especially by a singular stinking breath; but when they are voided by the mouth or anus, there remains no manner of doubt.

The cure is to be performed chiefly by destroying their nests, which is to be attempted by alkalious salts; gums which purge phlegm, mercurials, antimonials, and bitter aromatics.

*Earth WORM, Lumbricus*, a genus of insects of the class of the anarthra of a rounded shape and covered with a soft and tender skin, marked with annular ridges and furrows. This insect, when full grown is often ten inches in length, and more than a third of an inch in diameter; its colour is a dusky red, and its skin is formed into rings, but is smooth and soft to the touch.

*Guinea WORMS, Dracunculi*. See the article CUNCULI.

WORM, in gunnery, a screw of iron, to be fixed on the end of a rammer, to pull out the wad of a firelock, carbine or pistol, being the same with the wadhook, only the one is more proper for small arms, and the other for cannon.

WORM, in chemistry, is a long, winding, pewter pipe, placed in a tub of water, to cool and condense the vapours in the distillation of spirits.

WORM a cable, or hawser, in the sea-language, is to strengthen it by winding a small line all along between the strands.

WORM-SEED, *Semen Santonicum*, is the seed of a species of worm-wood which grows in the Levant, from whence we have the seed, which is there produced in great plenty without the trouble of sowing; this plant growing wild in the fields.

The seed of this plant is light and chaffy, enveloped with a vast number of thin membranes, that have the same virtue with the seed itself, and are used with it under its name.

It is a small and light seed, of a pale yellowish brown colour, with some admixture of greenish in it; of an oblong form, somewhat larger at the base, and tapering to a point at the summit. It is of a friable texture, easily beat to powder. It has not much smell, but is of a bitter taste.

Worm-seed is to be chosen large, fresh, and clean, not dusty or decayed, or hanging together in clusters, which is a sign of insects being, or having been among it.

Its great virtue is that of destroying worms in children: but as it is too bitter to be easily swallowed by them either in powder or decoction, it is therefore best taken by way of confit covered over with sugar. See the articles CONFIT and WORMWOOD.

WORMWOOD, *Abfathium*, in botany, a genus of plants, whose flower is composed of many tubulose hermaphrodite florets, which form the disc, and several female florets, which are naked, and compose the rays; they are contained in a roundish imbricated cup, and are succeeded by naked seeds, affixed to a hairy receptacle.

The common wormwood is perennial, and has a ligneous and fibrous root, with stalks of an indeterminate height, branched out into many small shoots, with large, hoary, winged, and serrated leaves, of a strong pungent smell and bitter taste. In the beginning of July, it produces several ligneous striated branches, having at their tops each a spike of small flowers, of a pale yellow, growing many together. This sort grows usually by the sides of highways and foot-paths, in many parts of England; but the Roman wormwood, which has leaves much smaller than the other, is propagated in gardens, and may easily be raised by planting the slips in the spring or autumn.

Of wormwood, there are only four sorts used in medicine, viz. the Roman wormwood, the small sort, or pontic, the sea wormwood, and the *abfathium alpinum*; besides these, botanists make twenty-eight other kinds, which are all included by Linnaeus among the artemisias. See the article ARTEMISIA.

Wormwood has always been looked upon as a valuable medicine, to promote the heat and circulation of the blood, and to recover the oscillation of the

which may happen either through the defect of a language which has none, or the fault of the man who has not yet learned them. Thirdly, to convey the knowledge of things. This cannot be done but when our ideas agree to the reality of things. He that has names without ideas, wants meaning in his words, and speaks only empty sounds. He that has complex ideas without names for them, wants dispatch in his expression. He that uses his words loosely, and unsteadily, will either not be minded or not understood. He that applies names to ideas, different from the common use, wants propriety in his language, and speak gibberish; and he that has ideas of substances disagreeing with the real existence of things, so far, wants the materials of true knowledge.

**WORD**, or *Watch WORD*, in an army or garrison, is some peculiar word or sentence, by which the soldiers know and distinguish one another in the night, &c. and by which spies and designing persons are discovered. It is used also to prevent surprises. The word is given out in an army every night to the lieutenant, or major general of the day, who gives it to the majors of the brigades, and they to the adjutants; who give it first to the field officers, afterwards to a serjeant of each company, who carry it to the subalterns. In garrisons it is given after the gate is shut to the town major, who gives it to the adjutants and they to the serjeants.

**WORKS**, *Opera*, in fortification, the several lines, trenches, ditches, &c. made round a place or army, or the like, to fortify and defend it.

**WORLD**, *Mundus*, the assemblage of parts which compose the universe. See the article **UNIVERSE**.

The duration of the world is a thing which has been greatly disputed. Plato after Ocellus Lucanus, held it to be eternal, and to have flowed from God as rays flow from the sun. Aristotle was much of the same mind; he asserts that the world was not generated so as to begin to be a world, which before was none: he lays down a pre-existing and eternal matter as a principle, and thence argues the world eternal. His arguments amount to this, that it is impossible an eternal agent, having an eternal passive subject, should continue long without action. His opinion was generally followed, as seeming to be the fittest to end the dispute among so many sects about the first cause. See the articles **MATTER**, **CAUSE**, and **PERIPATETIC Philosophy**.

Epicurus, however, though he makes matter eternal, yet shews the world to be but a new thing formed out of a fortuitous concourse of atoms. See the articles **ATOMICAL** and **EPICUREAN**.

Some of the modern philosophers refute the imaginary eternity of the world by this argument, that if it be *ab eterno*, there must have been a generation of individuals in a continual succession from all eternity, since no cause can be assigned why they

should not be generated, viz. one from another. Therefore to consider the origin of things, and the series of causes, we must go back in infinitum, i. e. there must have been an infinite number of men and other individuals already generated, which subverts the very notion of number. And if the cause which now generates has been produced by an infinite series of causes, how shall an infinite series be finite? Dr. Halley suggests a new method of finding the age of the world from the degree of the saltiness of the ocean. See **SEA**.

**WORMS**, in the Linnæan system of nature, a class of insects of the order of the apteria, and of the class of the anarthra.

The distinguishing character of this class is, that they have the muscles of their body affixed to a solid basis. The cure is to be performed chiefly by destroying their nests, which is to be attempted by alkalious salts; gums which purge phlegm, mercurials, antimonials, and bitter aromatics.

**Earth WORM, Lumbricus**, a genus of insects of the class of the anathra of a rounded shape and covered with a soft and tender skin, marked with annular ridges and furrows. This insect, when full grown is often ten inches in length, and more than a third of an inch in diameter; its colour is a dusky red, and its skin is formed into rings, but is smooth and soft to the touch.

**Guinea WORMS, Dracunculi.** See the article CUNCULI.

**WORM**, in gunnery, a screw of iron, to be fixed on the end of a rammer, to pull out the wad of a firelock, carbine or pistol, being the same with the wadhook, only the one is more proper for small arms, and the other for cannon.

**WORM**, in chemistry, is a long, winding, pewter pipe, placed in a tub of water, to cool and condense the vapours in the distillation of spirits.

**WORM** a cable, or hawser, in the sea-language, is to strengthen it by winding a small line all along between the strands.

**WORM-SEED, Semen Santonicum**, is the seed of a species of worm-wood which grows in the Levant, from whence we have the seed, which is there produced in great plenty without the trouble of sowing; this plant growing wild in the fields.

The seed of this plant is light and chaffy, enveloped with a vast number of thin membranes, that have the same virtue with the seed itself, and are used with it under its name.

It is a small and light seed, of a pale yellowish brown colour, with some admixture of greenish in it; of an oblong form, somewhat larger at the base, and tapering to a point at the summit. It is of a friable texture, easily beat to powder. It has not much smell, but is of a bitter taste.

Worm-seed is to be chosen large, fresh, and clean, not dusty or decayed, or hanging together in clusters, which is a sign of insects being, or having been among it.

Its great virtue is that of destroying worms in children: but as it is too bitter to be easily swallowed by them either in powder or decoction, it is therefore best taken by way of comfit covered over with sugar. See the articles COMFIT and WORM-WOOD.

**WORMWOOD, Absinthium**, in botany, a genus of plants, whose flower is composed of many tubulose hermaphrodite florets, which form the disc, and several female florets, which are naked, and compose the rays; they are contained in a roundish imbricated cup, and are succeeded by naked seeds, affixed to a hairy receptacle.

The common wormwood is perennial, and has a ligneous and fibrous root, with stalks of an indeterminate height, branched out into many small shoots, with large, hoary, winged, and serrated leaves, of a strong pungent smell and bitter taste. In the beginning of July, it produces several ligneous striated branches, having at their tops each a spike of small flowers, of a pale yellow, growing many together. This sort grows usually by the sides of highways and foot-paths, in many parts of England; but the Roman wormwood, which has leaves much smaller than the other, is propagated in gardens, and may easily be raised by planting the slips in the spring or autumn.

Of wormwood, there are only four sorts used in medicine, viz. the Roman wormwood, the small sort, or pontic, the sea wormwood, and the absinthium alpinum; besides these, botanists make twenty-eight other kinds, which are all included by Linnaeus among the artemisias. See the article ARTEMISIA.

Wormwood has always been looked upon as a valuable medicine, to promote the heat and circulation of the blood, and to recover the oscillation of

the

the fibres, while sluggish; by which means, the gross humours are attenuated, and brought back into the common road of circulation: it restores the debilitated functions of the viscera, and is an excellent stomachic: it is good in the dropsy, green-sickness, cachexies, and agues, which last it has often been known to cure. It also, by its great bitterness, is of some service against worms, by resolving the mucilaginous humours in which their eggs are contained: however, in all hot diseases and inflammatory dispositions it is not safe.

Several medicinal compositions are prepared from it; and, among others, the absinthites vinum, or wormwood-wine, which is made in the following manner: Take four pounds of the tops of each of the two first kinds, when fresh and in bloom, cleanse and either mince or bruise them; then put them, together with three drams of powdered cinnamon, into a barrel that will contain fifty quarts; fill the barrel with must, fresh expressed from the white grape, and set the barrel in a cellar, leaving the wine to ferment: when the fermentation is over, fill up the cask with white wine; bottle it and keep it for use.

Or it may be made in this manner, at any time: Take the dried leaves of the two sorts of wormwood, of each six drams, and pour thereon two quarts of white wine; then put them together into a large bottle, and set them in a cool place to macerate, twenty-four hours; then, having squeezed out the leaves, filtrate the liquor, which you may keep for use.

**WORSHIP**, the offering up of adoration, prayer, praise, thanksgiving, and confession to God, as our creator, benefactor, law-giver, and judge.

**WORSTED**, a kind of woollen thread, which, in the spinning, is twisted harder than ordinary. It is chiefly used either wove or knit into stockings, caps, gloves, or the like.

**WOULDING**, a sea term, for the winding of ropes round a mast or yard of a ship, that has been strengthened by a piece of timber nailed to it.

**WOUND**, *Vulnus*, in medicine and surgery, is frequently defined to be a violent solution of the continuity of the soft external parts of the body, made by some instrument. Others take a greater latitude in defining it, and call every external hurt of the body, by what cause soever produced, a wound. On the other hand, some are of opinion, that unless the injured parts of the body are divided by some sharp instrument, as by a sword or knife, it is by no means to be called a wound; but notwithstanding, it is certain that those wounds which are produced by blunt instruments may properly enough be called wounds, whence Heister distinguishes two different kinds of wounds, the one made by acute, the other by blunt instruments.

Wounds are generally inflicted upon the softer

parts of the human body, such as the skin, fat, muscular flesh, ligaments, blood-vessels, and nerves, and parts that are composed of these, as the viscera and intestines; yet the more solid parts of the body are by no means to be here excluded, as the bones, whence the parts that are subject to those injuries will afford two distinctions of wounds; one, wounds of the softer parts, the other, wounds of the bones.

As causes of wounds, all instruments of what kind soever, whether blunt or sharp, may properly be reckoned, provided they are of such a nature, that upon the violent external application of them, they are capable of producing a solution of continuity in the parts of the body upon which they are inflicted; for a solution of the external parts by internal cause, is not called a wound, but rather an abscess, or ulcer; so when the harder parts of the body (as the bones) are broken by a fall, or a violent blow received from a blunt instrument, it is called a fracture.

The effects which are produced by wounds, besides the division of the softer parts, are generally profusions of blood, though they are sometimes attended with much greater mischiefs than these; for it can scarcely happen, but that the divided parts must, in some measure, if not totally, lose their natural functions, according to the different uses for which the part is intended, and according to the different degrees of injury that it receives.

The greater number of uses a part is intended for by nature, the worse will be the consequences of a wound upon that part; this principle is so extensive, that it is the constant guide in forming a prognostic, whether a wound will prove mortal or not. He, therefore, who is best skilled in anatomy, that is, best instructed in the situation of the parts, and their uses, will be enabled to form the most accurate judgment of the consequence that will necessarily attend a wound upon any particular part.

What has been said of the different situations and causes of wounds, sufficiently demonstrates, that there are many different kinds of wounds, some brought on by a puncture, some by a stab, and some again by a blow; some are curable, others incurable; some are made with sharp instruments, others with blunt ones: with regard to their figure, some form a right line, others are curved, transverse, or oblique: with respect to their situation, some are placed in the head, others in the neck, thorax, or abdomen; and of these, some are internal, others external. Variety of different wounds arise from the great diversity of condition that wounds are left in; for in some wounds, the inflicting instrument, or part of it, remains; for instance, a leaden bullet, a piece of glass, or of a grenade; the points of arrows or swords: but in some wounds, nothing of this kind is left: sometimes fractures of the bones accompany wounds, which is generally the case in gun-

gun-shot wounds: some wounds are also attended with poison, as those which are made with poisoned arrows; under this head may be ranked the bites of animals, but more particularly of mad or venomous animals. Some are of opinion, that wounds which are made with copper, or silver instruments, should be reckoned in this class, the poison of which, if there is any, is owing to the vitriol that is mixed with these metals.

In slight wounds, where no considerable artery, nerve, or tendon is concerned, the following appearances are usually remarkable; at first sight, the wound appears as a red line drawn upon the part; but upon being dilated, the blood instantly gushes out in greater or smaller quantities, according to the size and number of the blood-vessels that are injured.

The hæmorrhage, after a short continuance, stops of its own accord, and the blood concreting in the wound, forms a crust; the lips of the wound now begin to look red, and swell, and are attended with some degree of pain and inflammation; if it is a large wound, a fever, that is to say, an universal heat and quickness of pulse, almost always ensue upon the third or fourth day; sooner or later, a white glutinous humour appears, not unlike oil, and this is known by the name of pus, or matter; upon appearance of matter, the redness, tumour, pain, inflammation, and fever, disappear entirely, or at least are abated; and these are the signs of a wound inclining to heal; for under the matter, new flesh springs up from the wounded vessels, which having by degrees filled the wound, dries upon its upper part, and forms a cicatrix. See the article CICA-TRIX.

In dangerous wounds, that is, where any considerable blood-vessel is wounded or divided, there generally ensues so violent a hæmorrhage, that the wounded person is in an instant sensible of great loss of spirits, and weakness, and faints away: and when the larger arteries are wounded, whether they are internal or external, he dies upon the spot; altho' somewhat less danger is apprehended from wounds that are inflicted upon the vessels, which are situated upon the external parts of the body (some few excepted) because they will admit of the ligature, and other means of restraining the violence of the hæmorrhage.

There is nothing will give a truer light into the nature and consequence of a deep wound, than a due consideration of what natural actions of the body are impeded thereby. For instance, in wounds of the breast, when the patient draws his breath with shortness and difficulty, and is at the same time attended with a hæmoptysis and hiccough, it may be rationally conjectured, that the lungs or the diaphragm are wounded; so in wounds of the abdomen, when chyle is voided, it is a plain indication that the stomach, small guts, or lacteals are wound-

ed: when excrements pass by the wound, the great guts are wounded.

Bilious blood likewise shews the liver or gall-bladder to be divided: if urine passes by the wound, the urinary bladder, or else the ureters, are wounded; and bloody urine denotes a blow on the kidneys, or a wound of the bladder; but when there are large profusions of blood this way, it is a sign that some of the larger blood-vessels are wounded: vomiting of blood declares the stomach to be the injured organ: violent pains attended with convulsive twitches, shew that a nerve is wounded, or else that some foreign substance is left in the wound. Whenever the senses are disordered after a wound received on the head, a concussion of the brain is much to be feared. Difficulty of breathing, pains in the breast, and hiccoughing, are symptoms of a wound in the diaphragm.

It is of bad consequence for a wound to be attended with a large tumour; but it is of the last consequence if it is attended with no degree of tumour at all: the first is an indication of great inflammation, the last of mortification; some degree of tumour is always therefore best in wounds.

In order to enquire what wounds admit of a cure, and what are incurable, Heister divides wounds into three sorts. 1. Some wounds are absolutely of themselves mortal. 2. Others are in their own nature mortal, if not relieved by timely assistance. And, 3. Others become mortal by accident or imprudent treatment, though they were otherwise curable.

1. We properly style those wounds mortal which are not to be remedied by all the art and industry of man. Thus, wounds are of this kind which are attended with so violent an hæmorrhage as to produce instant death: of this sort are reckoned wounds that penetrate the cavities of the heart, and all those wounds of the viscera where the large blood-vessels are opened; such are large wounds of the lungs, liver, spleen, kidneys, stomach, intestines, mesentery, pancreas, uterus; of the aorta, of the iliac, coeliac, renal, mesenteric, and carotid arteries: especially if they are wounded near their origin: of the subclavian also, or vertebral; of the vena cava, iliac vein, the internal jugular, vertebral, renal, mesenteric; of the vena porta, and of the larger veins that lie deep in the body, because their situation will not admit of proper applications to restrain the flux of blood. Heister therefore reckons, very justly, these among the wounds that are absolutely incurable, since they are not remediable either by astringents, ligature, or fire.

Those wounds also are not less mortal than the former, which obstruct, or entirely cut off the passage of the animal spirits to the heart; such are wounds of the cerebellum, of the medulla oblongata, and some violent strokes of the brain itself.

There is reason to apprehend very great danger, when

the small veins or arteries which are contained in the cranium, are injured; for the blood flowing from them into the internal sinuses of the brain, either produces too great a pressure upon those very tender parts of the brain, and so obstructs the course of the blood and spirits; or else, being corrupted, it putrifies the brain itself, if it cannot be evacuated by the assistance of the trepan; which is the case when this accident happens at the lower part of the cranium, or in the sinuses of the brain: nor is there less danger where the nerves, which tend to the heart, are wounded, or entirely divided; for, after this, it is impossible for the heart to continue its motion. See TREPAN.

To this class are to be referred also all wounds which entirely deprive the animal of the faculty of breathing: there is therefore great danger where the *aspera arteria* is entirely divided; for where it is only divided in part, it may be healed again by the assistance of an expert surgeon.

To this place also belong violent shocks of the bronchia, mediastinum, and diaphragm, especially the tendinous part of it. See the articles ASPERA ARTERIA, &c.

Those wounds also which interrupt the course of the chyle to the heart, are no less incurable than the former; such are wounds of the stomach, intestines, receptacle of the chyle, thoracic duct, and larger lacteals: to which may be also added, wounds of the oesophagus, if they are large; though death is not so sudden an attendant on these wounds; but, for want of nourishment, the persons afflicted by them are weakened by degrees, and at length die consumptive.

In this account, those wounds also are not to be omitted, which are inflicted upon membranous parts, that are situated in the abdomen, and contain some secreted fluid, as on the bladder (either of the bile or urine) the stomach, intestines, receptacle of the chyle, and lacteal vessels. The fluids contained in these parts, when once they are let loose into the cavity of the abdomen, cannot be properly discharged, and therefore easily corrode the internal parts of the body; and the membranes that contained them are generally so fine, that they will not admit of agglutination, especially since no medicine from without can be applied. A few indeed have recovered after slight wounds in these parts; but since the number of these instances is but few, and the cure in them has been accidental, and not performed by the surgeon's art, these may very justly be added to the list of mortal wounds. See ABDOMEN, &c.

2. Many wounds there are which, though the experienced surgeon could remedy, yet prove fatal if neglected or left to nature: of this number are those which produce instant death, unless relieved by present assistance; such are wounds of the larger external blood-vessels, which might be re-

medied by ligature, by the application of astringent medicines, or the actual cautery.

Of this kind are wounds of the brachial or crural artery, unless they are too near the trunk of the body; wounds in the large arteries of the cubit, or tibia; of the branches of the external carotid or temporal artery: to these also may be added, wounds of the jugular and other veins, situated upon the external parts of the body; but in these cases no help can be given, unless the surgeon be brought before there has been a vast profusion of blood. See CRURAL ARTERY, &c.

3. Wounds are properly said to become mortal by accident, where the patient's death, from them, is occasioned either by the ill conduct of the patient himself, or by the neglect or ignorance of his surgeon; the wound itself being of the number of those deemed curable by the judicious practitioner.

Under this head may be reckoned, 1. Those wounds which the surgeon has neglected to cleanse sufficiently, though he had it in his power to do it; as when some foreign body, which might easily have been extracted, is left in the wound, and produces inflammations, hæmorrhages, convulsions, and, finally, death itself: so in wounds of the thorax and abdomen, if the surgeon is not diligent in evacuating the grumous blood, it will corrupt there, and by drawing the neighbouring parts into consent, will expose the patient to death: great care must also be taken that the lips of the wound do not close, till the blood that is collected in the cavity of the body be all evacuated if possible, which will be easily perceived by the difficulty of breathing, and other bad symptoms going off; but if any of the larger internal vessels are wounded, then all attempts to discharge the blood are vain, for the violence of the hæmorrhage takes off the patient.

2. Wounds are also to be accounted mortal by accident, which are treated or searched in too rough a manner by the surgeon; for if wounds are handled roughly, which are full of nervous parts, or of large blood-vessels, there is danger of bringing on hæmorrhages, convulsions, inflammations, gangrenes, and finally, death itself.

3. The case is also the same in external wounds, which are slight of themselves, but under which the patient is lost by the inflammation, which is increased and brought on by the surgeon's injudicious treatment.

4. When any one is taken off by the violence of the hæmorrhage from a wound of the hand or foot; for in this case, the surgeon might have easily stopped the blood by the application of proper remedies, or by ligature.

5. When the patient is guilty of any intemperance in eating or drinking, or of any excess of passion, of exposing himself to the cold air, or of using violent exercise. For by these means, wounds, more especially those of the head, by being liable

to fresh hæmorrhages, and other dangerous accidents, frequently become mortal, notwithstanding they naturally would not prove so, and though the surgeon uses his utmost care and skill. See HÆMORRHAGE.

6. Among these, also, are to be accounted those wounds of the head, where the patient is lost by the vast quantity of blood which is extravasated in the cavity of the cranium, and confined there; but where he might have been relieved if the trepan had been applied in time; for though wounds of this kind generally prove incurable, yet, as there is at least a probability of saving a person in these circumstances, by the use of the trepan, this may properly be reckoned among the doubtful cases, and not deemed absolutely mortal.

7. And lastly, a bad habit of body prevents the cure of wounds, which would admit of an easy cure in healthy subjects; so we often see the slightest puncture on the hand or foot of an hydropical, consumptive, or scorbutic person, shall produce a gangrene, and prove mortal; though the surgeon spares no care nor application to prevent it. See GANGRENE, &c.

*Cure of WOUNDS.* Since a wound is a solution of the continuity of the parts of the body, the reunion of those parts seems to be the principal intention; but since wounds are of very different kinds, some slight, and others of great consequence, in proportion to this difference, so will the manner of prosecuting this intention differ.

The cure of slight wounds is generally performed with great ease, by applying a small portion of lint to the part, well saturated with spirit of wine, oil of eggs, turpentine, basilicon, the balsam of Arcæus, of Peru, securing the dressings with a plaster, and renewing them once in a day or two: by this means, the lips of the wound will presently agglutinate.

Wounds which are attended with some danger, are to be treated as follows: in the first place, the wound is to be cleansed of all extravasated blood, fordes, &c. in the next place, if a bullet, the point of a sword, any part of the clothing, a piece of glass, or any other foreign body, shall remain in the wound, it is to be removed by the fingers, or with proper instruments, as has been already explained under articles EXTRACTION and GUN-SHOT-Wounds; which see.

The hæmorrhage is to be stopped at the first dressing; the divided parts are to be brought as near each other as possible, and their situation is to be so maintained, that the cicatrix which is left may appear even.

Among the number of the most simple wounds, are reckoned those which are made by puncture, or stabbing upon the external parts, and not penetrating deep; for the method of treating which, see PUNCTURE.

The method of treating a cut, or such a wound

as is made by a cutting instrument, where no part of the flesh is taken off, and the accident happens to the external parts of the body, and does not penetrate deep, after the wound is cleansed, it should be dressed with the same vulnerary balsam, and the lips of the wound should be closed, and kept in that situation. This is done after different methods, according to the difference of the wound; as,

1. It is to be done by placing the wounded part in a proper posture, that is, as soon as the wound is dressed, the part should be placed in such a situation, that the divided parts may be most likely to keep in constant contact.

2. By a proper bandage, tying up the parts so that the lips may meet, and thereby easily unite.

3. By a proper suture, which differs according to the difference of the wound, but may be generally divided into the dry and bloody suture; the dry, or as some call it, the bastard suture, is the application of sticking plasters, to keep the lips of the wound united; the bloody, or true suture, is performing the same thing with a needle and thread. See SUTURE.

If the wound heals by the assistance of the suture, the threads or ligatures are to be cut near the knots; the lower lip of the wound is to be suspended with one hand, while the threads are gently drawn out by the other; the punctures that are left will easily heal by the application of a vulnerary water, called by the French, *l'eau d'arquebuse*; or by injecting aqua calcis, or spirit of wine, and laying on compresses dipped in the same liquors: but larger wounds are to be dressed with the balsam of Arcæus, or balsam of capivi, and the lips kept firm together, with some sticking plaster till a firm cicatrix is formed.

Where there is a loss of substance, the wound will not unite either by the help of plaster, or suture, till it is filled up with new flesh. For this purpose, you will find lint dipped in oil, or spread with some vulnerary balsam, or ointment, and applied to the bottom of the wound, very serviceable, covering it with a plaster, compress and proper bandages, and this dressing is to be repeated daily.

As hot or cold air is very hurtful to wounds, so it must by all means be kept from them; for which reason, the surgeon should be careful not to remove the old dressings till the fresh ones are got ready, and to be as expeditious as possible in applying them. After this, when a white, even, thick matter appears in the wound, it should be dressed as you see occasion, every day, or every other day; the superfluous matter should be wiped away with a very light hand; for it is better to leave some behind, than to treat the wound roughly. These rules being observed, the flesh will spring up presently, and the wound unite; and in order to perfect the cure of the wound, an even cicatrix should, if possible, be procured; for the method of obtaining which, see Pus.

When any uncleanness or foulness is perceived in a wound, that is, if the flesh is putrid, fungous, black, or livid, it must be well cleansed before any attempt is made to heal it; for which purpose, apply a digestive ointment, made with turpentine, yolk of eggs, and honey of roses; and where this is not strong enough, substitute the Egyptian ointment, or spirit of wine diluted; or, if you require more strength, use red precipitate mercury. Applications of this kind are to be continued till the wound is entirely clean; after which, recourse is to be had to the methods already prescribed.

If the new flesh should be luxuriant, and rise up so as to prevent the formation of an even cicatrix, it must be taken down with green vitriol, or a powder composed of burnt alum, and red precipitate mercury; at the same time making a proper pressure, with the plasters, compresses, and bandages, till the parts are even. See FUNGUS.

The patient should observe a strict regimen with regard to his diet and manner of life, as nothing forwards the cure so much as a good habit of body, which may be procured by observing a strict regularity with regard to diet, air, keeping the passions under, and indulging neither too much sleep, nor suffering too great wakefulness; and it is to be observed, that the greater tendency there is in a patient to a diseased state of body, so much the stricter course of life ought he to observe.

The bowels should by all means be kept open, especially in those who have received a wound in the head; however, it is to be observed, that strong cathartic medicines are to be avoided; but it is not only safe, but advisable, to eat and drink those things that may at the same time nourish and keep the body open. To this end the patient may drink plentifully of tea or coffee, may eat stewed prunes, roasted apples; but hard meats of all kinds are forbid: where the patient is so bound up, that a diet of this kind has no effect, it will be necessary to have recourse to medicines, but then those must be of the mildest kind; here a gentle clyster may be given, a suppository may be used, or an ounce or two of manna, or some purging salts in warm broth may be prescribed: whenever the violence of the wound, or the ill habit of the patient, require the use of internal remedies, vulnerary drinks will be found to be of the greatest consequence; in composing which, the constitution of the patient, and the nature of the complaint, should be diligently consulted; for if the patient is of a phlegmatic habit of body, cold, pale, or naturally subject to tumours, then the vulnerary decoction should be composed of herbs that attenuate and divide the blood. See the article ATTENUANTS.

If the patient has a thin sharp blood, then decoctions of viscous and glutinous plants will be proper; but if he is vexed with great pain or wakefulness,

then some opiates must be administered. See AGGLUTINANTS and OPIATES.

If he should be troubled with an acidity, absorbents are proper; and when a quickness of pulse and extraordinary heat are perceived, they are signs of a symptomatical fever. See FEVER.

For the disorders accompanying wounds, commonly called the symptoms of wounds, as hæmorrhages, pains, spasms, convulsions, &c. see HÆMORRHAGE, &c.

*WOUNDS in Horses.* The most terrible wounds these creatures are subject to, are those got in the field of battle. The farriers that attend camps, have a coarse way of curing these; but it is a very expeditious and effectual one.

If the bullet be within reach, they take it out with a pair of forceps; but if it lie too deep to be come at, they leave it behind, and dress up the wound in the same manner as if it were not there. They first drop in some varnish from the end of a feather, and when the bottom is thus wetted with it, they dip a pledget of tow in the same varnish, which they put into the wound, and then cover the whole with the following charge: take a quarter of a pound of powder of bole armenic, half a pound of linseed oil, and three eggs, shells and all; add to these, four ounces of bean flour, a quart of vinegar, and five ounces of turpentine; this is all to be mixed over the fire, and the wound covered with it.

This application is to be continued four or five days; then the tent put into the wound is to be dipped in a mixture of turpentine and hogs-lard; by this means a laudable matter will be discharged, instead of the thin sharp water that was at first. Then the cure is to be completed by dressing it with an ointment made of turpentine, first well washed, and then dissolved in yolks of eggs, and a little saffron added to it.

This is the practice in deep wounds that do not go through the part; but in cases where the bullet has gone quite through, they take a few weavers linen thrums, made very knotty; these they make up into a kind of link, and dipping it in varnish, they draw it through the wound, leaving the ends hanging out at each side; by means of these they move the link or skain three or four times a day, always wetting the new part that is to be drawn into the wound with fresh varnish.

They put on a charge of bole armenic, &c. as before described, on each side of the wounded part, and continue this as long as the wound discharges thin watery matter, or the sides continue swelled. After this, they dress it with the ointment of turpentine, yolks of eggs, and saffron, till it is perfectly cured.

The other methods are the dressing the wound with an ointment made of wax, turpentine, and lard, and covering it with linen rags wetted with cream;

cream; or the dressing, with a mixture of yolks of eggs, honey, and saffron, and covering it with cream and balm leaves beaten together.

When the wound is so dangerous as to require the assistance of internal medicines, they give the following pills: take assa-foetida, bay-berries, and native cinnabar, of each a pound; beat up the whole into a mass with brandy, and roll it into pills of fourteen drams weight each. These are to be laid in a shady place to dry, after which they will keep a long time without any damage. The horse is to take two of these every other day, or, if necessary, every day, till he has taken eight or ten of them; and he is to stand bridled two hours before and after taking them.

When the wound seems at a stand, not appearing foul, and yet not gathering new flesh, there must be recourse had to the following powder, whose effect in bringing new flesh is wonderful: take dragon's-blood and bole armenic, of each two ounces; mastic, olibanum, and sarcocolla, of each three drams; aloes, round birth-wort, and common iris root, of each a dram a half; make the whole into a fine powder. This is sometimes used dry, sprinkling it on the wound; but sometimes it is mixed with turpentine, sometimes with juice of wormwood, and sometimes with honey of roses, and either way does very well.

When the wound grows foul, and requires a detergent to cleanse it, the common liquor for this purpose is a phagedenic water, which they make of lime-water and sublimate in this manner: take two pounds and a half of newly made and unslacked lime, put it into a pewter vessel, and pour on it five quarts of boiling water; when the bubbling is over, let it stand to rest two or three days, stirring it often with a stick: then pour it clear off, after a due time, for the lime to settle; and filtre it through some whited-brown paper, made for the lining of funnels on this occasion.

To a quart of clear lime-water thus prepared, add eight ounces of spirit of wine, and one ounce of spirit of vitriol; when these are well mixed by shaking them together, then add an ounce of corrosive sublimate in fine powder: mix all well together, and keep the whole in a bottle to be used for cleansing these foul wounds, and on any other occasion where there may be a detergent of this powerful kind necessary. It will keep good many years.

If this water will not thoroughly cleanse the wound, but there still will remain a quantity of foul matter in it, and there is danger of a gangrene, they add to it as much arsenic, in fine powder, as there was of the corrosive sublimate; that is, at the rate of an ounce to a quart and half a pint. See GANGRENE.

WRACK, *Fucus*, in botany. See the article FUCUS.

WRACK, or *Ship-WRACK*. See WRECK.

WREATH, in heraldry, a roll of fine linen or silk (like that of a Turkish turban) consisting of the colours borne in the escutcheon, placed in an achievement between the helmet and the crest, and immediately supporting the crest. See the article CREST, &c.

WRECK, or *Ship-WRECK*, in law, is when a ship perishes on the sea, and no person escapes alive out of it. In this case, if the ship so perished, or any part thereof, or the goods of the ship come to the land of any lord, and are left there, the lord shall have the same, as being a wreck of the sea: but if any single person, or even a dog, or other living creature, escape alive out of the ship, the party to whom the goods belong, may come within a year and a day, and proving the goods to be his, he shall have them again. And it is held, that they are no wrecks so long as they remain at sea, within the jurisdiction of the admiralty.

It is enacted by 12 Ann. c. 18. that if any wreck happen by any fault or negligence of master or mariners, the master must make good the loss; but if the same was occasioned by tempest, enemies, &c. he shall be excused: making holes in ships, or doing any thing wilfully tending to the loss thereof, is by that statute declared felony.

WRECK, in metallurgy, a vessel in which the third washing is given to the ores of metals.

WREN, in ornithology, the chestnut-coloured motacilla, with the wings variegated with white and grey. See MOTACILLA.

WRESTLING, a kind of combat or engagement between two persons unarmed, body to body, to prove their strength and dexterity, and try which can throw his opponent to the ground.

It was the custom for the Athletæ to anoint their bodies with oil, to give the less hold to their antagonist. Lycurgus ordered the Spartan maids to wrestle in public, quite naked, in order to break them of their too much delicacy and niceness, to make them appear more robust, and to familiarize the people to such nudities.

WRIST, *Carpus*, in anatomy, a part of the hand, consisting of eight small, unequal, and irregular bones, all which taken together, represent a sort of grotto, of an irregular quadrangular figure, and connected principally with the basis of the radius. See HANB.

WRIST, in the manege. The bridle-wrist is that of the cavalier's left hand. A horseman's wrist and his elbow should be equally raised, and the wrist should be two or three fingers above the pommel of the saddle.

WRIT, in law, signifies in general the king's precept in writing under seal, issuing out of some court, directed to the sheriff, or other officer, and commanding something to be done in relation to a suit or action, or giving commission to have the same done. And, according to Fitzherbert, a writ

is

is said to be a formal letter of the king in parchment, sealed with his seal, and directed to some judge, officer, or minister, &c. at the suit of a subject, for the cause briefly expressed, which is to be determined in the proper court according to law.

**WRIT of Assistance**, is a warrant that issues out of the Exchequer, to authorize persons to take a constable, or other public officer, to seize goods or merchandizes prohibited and uncustomed, &c. by virtue of which writ, any person may, in day time, and in the presence of such constable, &c. break open doors, chests, warehouses, and other places, to search for and seize uncustomed goods.

There is also a writ of this name that is used to give possession of land; and likewise for the general assistance of sheriffs, &c.

**WRIT of Inquiry and Damages**, a judicial writ that issues out to a sheriff upon a judgment by default, in action of the case, covenant, trespass, trover, &c. commanding him to summon a jury to enquire what damages the plaintiff hath sustained, occasione præmissorum; and when this is returned with the inquisition, the rule for judgment is given upon it; and if nothing be said to the contrary, judgment is thereupon entered.

**WRIT of Rebellion**, is a writ issuing out of the court of Chancery or Exchequer, against a person who is in contempt for not appearing in one of these courts, &c. See the article *COMMISSION of Rebellion*.

**WRITER of the Tallies**, an officer of the Exchequer, being clerk to the auditor of the receipt, who writes upon the tallies the whole letters of the teller's bill. See the article *TALLY*.

**WRITING**, *Scriptura*, the art or act of signifying and conveying our ideas to others, by letters, or characters visible to the eye.

Writing is now chiefly practised among us by means of pen, ink, and paper; though the ancients had other methods.

To write without blacking the fingers, Mr. Boyle directs as follows: prepare the paper with a fine powder made of three parts of calcined copperas, two of galls, and one of gum Arabic; these being fresh mixed, rub them with a hare's foot into the pores of the paper, and write with fair water, and the letters will immediately appear black.

To make new writing appear old, the same author directs to moisten it well with oil of tartar per deliquium, more or less diluted with water, as you desire the ink to appear more or less decayed.

We may write without ink or its materials: for this purpose, take a fine powder of calcined hartshorn, of clean tobacco-pipes (or rather of mutton bones burnt to a perfect whiteness) and rub it upon the paper, and then write with a silver bodkin, or the like.

**WRY-NECK**, *Jynx*, in ornithology. See *JYNX*.

**WYCH-HOUSE**, a house in which salt is boiled. See *SALT*.

**WYDRAUGHT**, a water-couse, or water-passage, to carry off the filth of a house; properly a sink, or common sewer. See the articles *CLOACA* and *SEWER*.

**WYKE**, anciently signified a farm, hamlet, or little village.

**WYTE**, or **WITE**, in our ancient customs, a pecuniary penalty or mulct.

# X.

## X A N

**X**, The twenty-second letter of our alphabet, and a double consonant. It was not used by the Hebrews or ancient Greeks; for as it is a compound letter, the ancients, who used great simplicity in their writings, made use of and expressed this letter by its component parts *cs*. Neither have the Italians this letter, but express it by *ff*.

**X** begins no word in our language, but such as are of Greek original, and is in few others, but what are of Latin derivation; as, *perplex*, *defluxion*, &c. We often express this sound by single letters, as *cks*, in *backs*, *necks*; by *ks*, in *books*, *breaks*; by *cc*, in *accels*, *accident*; by *ct*, in *action*, *unction*, &c. The English and French pronounce it like *cs*, or *ks*; the Spaniards, like *c* before *a*, viz. *Alexandro*, as if it were *Alecandro*.

In numerals, it expresses 10, whence in old Roman manuscripts it is used for *denarius*; and as such, seems to be made of two V's, placed one over the other. When a dash is added over it, thus,  $\overline{x}$ , it signifies ten thousand.

**XANTHICA**, in antiquity, a Macedonian festival, so called because it was observed in the month Xanthus, which, as Suidas tells us, was the same with April.

At this time, the army was purified by a solemn lustration, in the following manner: they divided a bitch into two halves, one of which, together with the entrails, was placed upon the right hand, the other upon the left; between these the army marched in this order: after the arms of the Macedonian kings, came the first part of the army; these were followed by the king and his children; after whom went the life-guards, and the rest of the army. This done, the army was divided into two parts, one of which being set in array against the other, there followed a short encounter, in imitation of a fight.

**XANTHIUM**, the lesser burdock, in botany, a genus of plants, producing male and female flowers; the corolla is compound, uniform, tubulose, and

## X I M

equal, and disposed in an hemispherical form; the partial flower is monopetalous, tubulose, funnel-shaped, erect, and divided into five segments at the limb: the fruit is a dry ovato-oblong berry, bifid at the apex, hairy, and covered with hooked prickles, containing an oblong seed, plane on one side, and convex on the other.

**XERANTHEMUM**, the Austrian sneeze-wort, in botany, a genus of plants, whose flower is compound and unequal; the corollulæ, which form the disc, are tubulose and hermaphrodite; and a few female quinquifid florets compose the radius: there is no pericarpium; but the cup, which is imbricated and cylindric, contains the seeds, which are oblong and crowned with hair.

The flowers of these plants being gathered when full blown, and properly dried, will continue fresh and beautiful several months; and by dipping them into various tinctures, they may be stained of different colours. They are propagated by sowing the seeds, either in spring or autumn, and afterwards the plants should be set where they are intended to blow. See plate XCVI. fig. 6.

**XEROPHAGIA**, in church-history, the eating of dried foods: so the ancient Christians called certain fast days, on which they eat nothing but bread and salt, and drank only water: sometimes they added pulse, herbs, and fruits. This sort of fasting was observed chiefly in the holy week, out of devotion, and not by obligation.

**XESTA**, an Attic measure of capacity. See the article MEASURE.

**XIMENIA**, in botany, a genus of plants, whose flower consists of four oblong petals; the inward ones are pilose, and the under ones are erect in the tube, and revolute: the stamina are eight erect short filaments, topped with linear obtuse antheræ: the fruit is an oval drupe, including a roundish nut with one cell, which contains a smooth kernel of the same form.

## X Y L

**XIPHIAS**, the sword-fish, in ichthyology, a genus of the acanthopterigious class of fishes. About fifteen feet in length is the size of a moderately large one, but it is frequently met with much bigger. See plate XCVI. fig. 4.

**XIPHIAS**, is also a fiery mereor, in form of a sword. It differs from the acontias in this, that the latter is longer, and more like a dart; and the former shorter and broader in the middle.

**XIPHION**, in botany, a genus of plants, differing from the iris by having a bulbous root and subulated leaves; but by Linnæus is classed among them. See **IRIS**.

**XIPHOIDES**, in anatomy, a cartilage adhering to the sternum; called also cartilago ensiformis. See **STERNUM**.

**XYLO-ALOES**, or **ALOE-WOOD**, in pharmacy, a drug distinguished into three sorts; the calambac, the common lignum aloes, and calambour.

The calambac, or finest aloe-wood (called by authors, lignum aloes prestantissimum, and, by the Chinese, sukhiang) is the most resinous of all the woods we are acquainted with: it is of a light spongy texture, very porous, and its pores so filled up with a soft and fragrant resin, that the whole may be pressed and dented by the fingers like wax, or moulded about by chewing in the mouth, in the manner of mastic.

This kind, laid on the fire, melts in great parts like resin, and burns away in a few moments, with a bright flame and perfumed smell. Its scent, while in the mass, is very fragrant and agreeable; and its taste acrid and bitterish, but very aromatic and agreeable: it is so variable in its colour, that some have divided it into three kinds; the one variegated with black and purple; the second, with the same black, but with yellowish instead of purple; and the third, yellow alone, like the yolk of an egg: this last is the least scented of the three; the substance, however, in them all, is the same in every respect, except the colour. It is brought from Cochinchina.

The lignum aloes vulgare, is the second in value. This is of a more dense and compact texture, and consequently less resinous than the other: there is some of it, however, that is spongy, and has the holes filled up with the right resinous matter; and all of it, when good, has veins of the same resin in it.

We meet with it in small fragments, which have been cut and split from larger; these are of a tolerably dense texture, in the more solid pieces, and of a dusky brown colour, variegated with resinous black veins. It is in this state very heavy, and less fragrant than in those pieces which shew a multitude of little holes, filled up with the same blackish matter that forms the veins in others. The woody part of these last pieces is somewhat darker than the other,

## X Y R

and is not unfrequently purplish, or even blackish. The smell of the common aloe-wood is very agreeable, but not so strongly perfumed as the former. Its taste is somewhat bitter and acrid, but very aromatic. This is also brought from Cochinchina, and sometimes from Sumatra.

The calambour, or, as some write it, the calambouc, is also called agallochum sylvestre, and lignum aloes Mexicanum. It is a light and friable wood, of a dusky and often mottled colour, between a dusky green black, and a deep brown. Its smell is fragrant and agreeable, but much less sweet than that of either of the others; and its taste bitterish, but not so much acrid or aromatic as either of the two former. We meet with this very frequently, and in large logs; and these sometimes entire, sometimes only the heart of the tree, the cortical part being separated. This is brought from the island of Timor, and is the aloe-wood used by the cabinet-makers and inlayers.

The Indians use the calambac by way of incense, burning small pieces of it in the temples of their gods; and sometimes their great people burn it in their houses, in times of feasting.

It is esteemed a cordial, taken inwardly; and they sometimes give it in disorders of the stomach and bowels, and to destroy worms. A very fragrant oil may be procured from it, by distillation, which is recommended in paralytic cases, from five to fifteen drops. It is at present, however, but little used, and would scarce be met with any where in the shops, but that it is an ingredient in some of the old compositions.

**XYLO-BALSAMUM**, a name which naturalists give to the wood of the tree which yields that precious gum known to the Latins by the name of opobalsamum, and to us by the name of balm of Gilead.

We have branches of this tree brought from Cairo; they are very straight, brittle, unequal, and full of knots; their bark is reddish without, and greenish within.

The xylo-balsamum is reputed good to strengthen the brain and stomach, and to expel poison. See **BALSAM**.

**XYLO-CASIA**, in the materia medica, the same with the cassia-ligna. See **CASSIA**.

**XYLON**, in botany, a name used by some authors for the bombax of Linnæus. See the article **BOMBAX**.

**XYLOPIA**, in botany, a genus of plants, whose flower consists of six sessile, linear, lanceolated, coriaceous petals, the three outward ones being larger: the stamina have no filaments, but consist of numerous antheræ sitting on the germen: the fruit is a dry, roundish, unilocular drupe, containing a roundish kernel.

**XYRIS**, in botany, a genus of plants, whose flower

## Y A C

flower consists of three plane, patent, large, crenated petals, with narrow unguis the length of the cup: the stamina are three slender filaments, shorter than the corolla, and topped with oblong erect antheræ: the fruit is a roundish trilocular capsule, opening with three valves, and contains a great number of very small seeds. See plate XCVI. fig. 3.

**XYSTARCHA**, in antiquity, the master and director of the xystus.

In the Greek gymnasium, the xystarcha was the

## W Y A M

second officer, and the gymnasiarcha the first; the former was his lieutenant, and presided over the two xysti, and all exercises of the athletæ therein. See the next article.

**XYSTUS**, among the Greeks, was a long portico, open or covered at the top, where the athletæ practised wrestling and running: the gladiators who practised therein, were called xystici.

Among the Romans, the xystus was only an alley, or double row of trees, meeting like an arbour, and forming a shade to walk under.

## Y.

**Y**, The twenty-third letter of our alphabet; its sound is formed by expressing the breath with a sudden expansion of the lips from that configuration by which we express the vowel *u*. It is one of the ambigenial letters, being a consonant in the beginning of words, and placed before all vowels, as in *yard*, *yield*, &c. but before no consonant. At the end of words it is a vowel, and is substituted for the sound of *i*, as in *try*, *descri*. In the middle of words it is not used so frequently as *i* is, unless in words derived from the Greek, as in *chyle*, *empyrean*; though it is admitted into the middle of some pure English words, as in *dying*, *flying*, &c.

The Romans had no capital of this letter, but used the small one in the beginning and last syllables of words, as in *martyr*, *onyx*.

Y is also a numeral, signifying 150, or, according to Baronius, 159; and, with a dash over it, thus,  $\overline{Y}$ , it signified 150,000.

**YACHT**, or **YATCH**, a vessel with one deck, carrying from four to twelve guns. See **SHIP**.

**YAM**, in botany, a species of *dioscorea*. See the article **DIOSCOREA**.

This plant is much cultivated in the West-Indies: the root is the size of a man's leg, of an irregular form, and of a dirty brown colour on the outside, but when cut, is white and mealy within.

The stalks of this plant are triangular and winged; the leaves are heart-shaped; the stalks climb to the height of ten or twelve feet, when they grow near trees or shrubs, to which they fasten themselves, otherwise they trail on the ground.

Yams are propagated by cutting the root into pieces, observing to preserve an eye or bud to each, as is practised in planting potatoes; each piece being planted will grow, and produce three or four large roots. In America, they are six or eight months in the ground before the roots are taken up for use. These roots are roasted or boiled, and eaten by the inhabitants, and sometimes made into bread.

This plant cannot be preserved in this country without the aid of a hot-house, on account of its tenderness and susceptibility of cold.

**YARD**,

**YARD**, a measure of length used in England and Spain. See **MEASURE**.

**YARD**, in anatomy. See the article **PENIS**.

**YARD-ARM**, is that half of the yard that is on either side of the mast, when it lies athwart the ship.

**YARD-LAND**, is taken to signify a certain quantity of land, in some counties being fifteen acres, and in others twenty; in some twenty-four, and in others thirty and forty acres.

**YARDS of a Ship**, are those long pieces of timber which are made a little tapering at each end, and are fitted each athwart its proper mast, with the sails made fast to them, so as to be hoisted up, or lowered down, as occasion serves. See **SHIP**.

**YARE**, among sailors, implies ready, or quick. It is sometimes also used by seamen for bright.

**YARN**, wool or flax, spun into thread, of which they weave cloth. See **CLOTH**, **WOOL**, &c.

**YARRINGLE**, a kind of instrument, or reel, on which hanks of yarn are wound, to clues or balls. See **REEL**.

**YARROW**, *Achillea*, in botany. See the article **ACHILLEA**.

**YAWNING**, *Oscitatio*, an involuntary opening of the mouth, occasioned by a vapour, or ventosity, endeavouring to escape, and generally witnessing an irksome weariness, or an inclination to sleep.

Yawning, according to Boerhaave, is performed by expanding, at one and the same time, all the muscles capable of spontaneous motion; by greatly extending the lungs; by drawing in gradually and slowly a large quantity of air, and gradually and slowly breathing it out, after it has been retained for some time, and rarified, and then restoring the muscles to their natural state. Hence, the effect of yawning is to move, accelerate, and equally distribute all the humours through all the vessels of the body, and, consequently, to qualify the muscles and organs of sensation for their various functions.

Sanctorius observes, that a great deal is insensibly discharged, when nature endeavours to get rid of the retained perspirable matter, by yawning and stretching of the limbs. To these a person is most inclined just after sleep, because a greater quantity going off by the pores of the skin, than at other times, whensoever a person wakes, the increased contraction that then happens, closes a great deal of the perspirable matter in the cutaneous passages, which will continually give such irritations, as excite yawning and stretching; and such motions, by shaking the membranes of the whole body, and shifting the contacts of their fibres and the inclosed matter, by degrees throw it off. Hence we see the reason, why healthful strong people are most inclined to such motions, because they perspire most in time of sleep, and therefore have more of the perspirable matter to lodge in the pores, and greater irritations thereunto.

**YAWS**, in the sea-language. A ship is said to

make yaws when she does not steer steady, but goes in and out when there is a stiff gale.

**YAWS**, a distemper endemial to Guinea and the hotter climates in Africa.

It makes its first appearance in little spots on the cuticle, not bigger than a pin's point, which increase daily, and become protuberant, like pimples. Soon after, the cuticle frets off; and then, instead of pus or ichor, there appears white sloughs or fordes, under which is a small red fungus. These increase gradually, some to the size of a small wood-strawberry, others to that of a raspberry, others again exceed the largest mulberry, which in shape they very much resemble. In the mean time, the black hair growing in the yaws turns to a transparent white. See the articles **CUTICLE**, &c.

It is not easy to determine the exact time which the yaws take in going through their different stages. Lusty well-fed negroes have had several yaws as big as a mulberry in a month's time; whereas the low in flesh, with a scanty allowance, have passed three months without their growing to the size of a strawberry.

They appear in all parts of the body, but are most plentiful, and of the largest size, about the groin, privy parts, anus, arm-pits, and face; they are largest when fewest in number, and vice versa. They are not painful, unless handled roughly, nor cause a loss of appetite. They continue long without any sensible alteration; and some are of opinion, that as soon as the funguses become dry, the infection is exhausted.

The yaws are not dangerous, if the cure is skilfully managed at a proper time. But if the patient has been once salivated, or has taken any quantity of mercury, and his skin once cleared thereby, the cure will be very difficult, if not impracticable. The following form of medicine is recommended as a cure: take of flowers of sulphur, one scruple; of camphor dissolved in spirit of wine, five grains; of theriaca andromachi, one dram; and as much of syrup of saffron as will make a bolus. Let the bolus be taken at going to rest, which must be repeated for a fortnight or three week, till the yaws come to the height. Then throw the patient into a gentle salivation, with calomel given in small doses, without farther preparation. After salivation, sweat the patient twice or thrice, on a frame or chair, with spirit of wine, and give the following electuary: of aethiops mineral, one ounce and a half; of gum guaiacum, half an ounce; theriaca andromachi, and conserve of red roses, of each one ounce; oil of saffras, twenty drops; and as much of syrup of saffron as is requisite for an electuary. Of this, let two drams be taken in the morning and at night. He may likewise drink the decoction of guaiacum and saffras fermented with molasses, for his constant drink, while the electuary is taking, and a week or a fortnight after the electuary is spent. Some-

Sometimes there remains one large yaw, high and knobbed, red and moist; this is called the master-yaw. This must be consumed an eighth or a tenth part of an inch below the skin, with corrosive red mercury, and burnt alum, of each an equal quantity, and digested with one ounce of yellow basilicon, and one dram of red corrosive mercury; and cicatrized with lint pressed out of spirit of wine, and with the vitriol-stone. See FUNGUS and CICA-TRIX.

**YEAR**, *Annus*, the time the sun takes to go through the twelve signs of the zodiac. This is properly the natural or tropical year, and contains 365 days, 5 hours, and 49 minutes. See the articles SIGN and ZODIAC.

As for the Gregorian, the civil, the solar or astronomical, the bisextile, and Platonic years, see them under the articles GREGORIAN, CIVIL, &c.

The Julian year derives both its name and institution from Julius Cæsar the dictator; for before his time the form of the Roman year was so corrupted by the indiscretion of the pontiffs, in whose hands the power of intercalation was lodged, that the winter-months fell back to the autumn, and those of autumn to the summer. To remedy these inconveniences, the dictator not only added to that year (in which he set about the reformation of the calendar) the common intercalation of 23 days, between the 23d and 24th days of February, pursuant to Numa Pompilius's institution, but likewise 67 days more between November and December, so that this year contained 445 days. This done, he instituted a solar year, of 365 days and 6 hours, pursuant to what he had learned from the Egyptians, and every fourth year he ordered a day to be added.

The Arabs, Saracens, and Turks, count their year by the motion of the moon, making it consist of 12 moons, or months; whereof some have 30, and some 29 days, alternately; and these altogether make 354 days, and constitute a common lunar year: and 354 days, 8 hours, 48 minutes, 38 seconds, 12 thirds, constitute what is called a lunar astronomical year.

The Greeks counted their year by the motion of both sun and moon; and finding that there was 11 days difference between the lunar and solar years, at first they added an intercalary month every two years, containing 22 days. Afterwards, considering the 6 hours also, they put their embolism off 4 years, and then making the 3 first years to contain 354 days each, this made the fourth year to have 399 days: and to make this intercalation the more remarkable, they instituted the Olympic games on every such fourth year; whence came the computation by Olympiads. See OLYMPIAD.

The Egyptians had two sorts of years, the erratic and the fixed, or ætiac. The erratic was called the Nabonassarean, from the epocha which takes

its rise from Nabonassar, king of the Chaldees. As it neglects the 6 hours, which, in the Julian form, make a leap-day once in four years, its beginning anticipates the Julian every fourth year by a day, and therefore it is justly called erratic.

The anticipation of 1 day in 4 years, gains of the Julian years 1 in 1460; so that 1461 Nabonassarean years make but 1460 Julian years.

The fixed Egyptian year observes the Julian form of 365 days and 6 hours, making a leap-day of the 6 hours once in 4 years. It differs from the Julian in this, that its months are the same with those of the Nabonassarean; that it begins on August 29, instead of January 1, or, on August 30, if it be a leap-year; that it takes in the leap-day, not in February, but at the end of the year. See EPOCHA and INTERCALARY.

The Persian erratic year goes by the name Yezdegerdic, by reason that the Persian epocha commences from the death of Yezdegird, the last Persian king, who was killed by the Saracens. It consists of 12 months, containing 30 days each, and 5 supernumerary ones; so that it differs from the Nabonassarean only in the names of the months, and the commencement of the epocha.

The Getalean year, used also by the Persians, is very well adapted to the solar motions. It takes in a leap-day every fourth year, but every sixth or seventh turn it throws it forward to the fifth year, by which means the equinoxes and solstices are fixed to almost the same days of the month.

The Syrian year consists of 365 days and 6 hours, being divided into 12 months of equal extent with those of the Julian year, to which they correspond. This year begins October 1, so that the month called Tishrim, agrees with our October. The astronomical year is two-fold, viz. the tropical and fidereal: by the latter, is meant that space of time which the sun takes in departing from a fixed star, and returning to the same again. This year consists of 365 days, 6 hours, and 10 minutes.

As the form of the year is various among different nations, so likewise is the beginning: the Jews began their ecclesiastical year with the new moon of that month whose full moon happens next after the vernal equinox; and every seventh year they kept as a sabbatic year, during which they let their land lie at rest. The ancient Jewish year was made to agree with the solar year, by the adding of 11, and sometimes of 12 days, at the end of the year, or by an embolismic month.

The beginning of the Athenian or Attic year, was reckoned from that new moon, the full moon of which comes next after the summer solstice.

The Macedonian lunar year agrees with the Athenian, excepting that the former takes its beginning, not from the summer-solstice, but from the autumnal equinox.

The Ethiopic year is a solar year, agreeing with the

the ætiac or fixed Egyptian year, except in this, that the names of the months are different, and that it commences with the Egyptian year, on August 29 of the Julian year.

The Arabian or Mahometan year is called also that of the hegira, because the calculation of these years runs from the epocha of the hegira, when Mahomet fled from Mecca to M-dina. They had 12 civil months in a year, which contained 29 and 30 days, by turns, abating for their leap-years, in which the month Dulheggia has always 30. See **HEGIRA**.

The Mahometans begin their year when the sun enters Aries; the Persians, in the month answering to our June; the Chinese, and most of the Indians, begin it with the first moon in March.

At Rome, there are two ways of computing the year, the one beginning at the nativity of our Lord, which the notaries use; the other in March, on occasion of the incarnation, and it is from this the bulls are dated.

In England, the civil or legal year, as well as the historical year, commences January 1, by the late act for the alteration of the style. The church, as to her solemn service, begins the year on the first Sunday in Advent, which is always that next St. Andrew's day.

**YEAR and DAY**, in law, signifies a certain time that by law determines a right, or works prescription in divers cases; as in the case of an estray, if the owner do not challenge it within that time, it becomes forfeited to the lord; so of a wreck, &c. The like time is given to prosecute appeals in; and where a person wounded, dies in a year and a day after the wound received, it makes the offender guilty of murder. See **ESTRAY**, &c.

There is also year and day and waste, which is taken to be part of the king's prerogative, whereby he challenges the profits of the lands and tenements for a year and a day, of those that are attainted of petty treason or felony; and the king may cause waste to be made on the lands, &c. by destroying the houses, ploughing up the meadows and pastures, rooting up the woods, &c. unless the lord of the fee agrees with him for the redemption of such waste.

**YELLOW**, one of the original colours of light. See **COLOUR** and **LIGHT**.

**YELLOW**, in dyeing, is one of the five simple and mother colours. See **COLOUR** and **DYEING**.

**YELLOW**S, a disease in a horse, much the same with that called the jaundice in man.

There are two kinds of it, the yellow and the black. The yellow is a very frequent disorder, say the farriers, arising from obstructions in the gall-pipe, or the little ducts opening into the same, occasioned by viscid or gritty matter lodged therein, or a plenitude and compression of the neighbouring blood-vessels, by means whereof the matter that should be turned into gall, is taken up by the vein

and carried into the mass of blood, which it tinctures yellow, so that the eyes, inside of the lips, and other parts of the mouth capable of shewing the colour, appear yellow. The effect whereof is, that a horse will be dull, heavy, and low-spirited, easily jaded by the least labour or exercise, &c.

The black is known by other symptoms: the whites of the eyes, mouth, and lips, turn to a dusky colour, and not so clear and sanguine as before.

For the cure of this disease, we are directed to dissolve an ounce of mithridate in a quart of ale, or beer, and to give to the horse lukewarm; or instead of mithridate, two ounces of Venice-treacle; and if that is not to be had, three spoonfuls of common treacle.

This distemper is also incident to black cattle. The cure is, to bleed them in the ears, eyes, and tail; to put salt into their ears, and to rub them between your hands: and when blooded, give them two handfuls of salt down their throats, dry over night. In the morning, let them have fenugreek, turmeric, long-pepper, annise-seed, and liquorice, but two penny-worth in all, made into a powder, and given in a quart of ale, milk-warm.

**YELLOW-HAMMER**, in ornithology, a species of frangilla, with a yellow head and a greyish yellow body. See **FRANGILLA**.

**YEOMAN**, the first or highest degree among the plebeians of England, next in order to the gentry. The yeomen are properly freeholders, who having land of their own, live on good husbandry.

**YEOMAN**, is also a title of office in the king's household, of a middle place or rank between an usher and a groom.

**YEOMEN of the Guard**, were antiently two hundred and fifty men of the best rank under gentry, and of larger stature than ordinary, each being required to be six feet high. At present there are but one hundred yeomen in constant duty, and seventy more not in duty; and as any of the hundred dies, his place is supplied out of the seventy.

They go dressed after the manner of Henry VIII's time. They formerly had diet as well as wages, when in waiting, but this was taken off in the reign of queen Anne.

**YEST**, **YEAST**, or **BARM**, a head or scum rising upon beer or ale, while working or fermenting in the vat. It is used for a leaven or ferment, in the baking of bread, as serving to swell or puff it up very considerably in a little time, and to make it much lighter, softer, and more delicate. When there is too much of it, it renders the bread bitter.

The faculty of medicine of Paris, by a decree of March 24, 1688, solemnly maintained it noxious to the health of the people: yet could not that prevent its progress. See **BAKING** and **BREAD**.

**YEW-TREE**, *Taxus*, in botany. See **TAXUS**.

**YEW**, is also a term used by the salt-workers of Limington, and some other parts of England, to express

express the first rising of a scum upon the brine in boiling. See the article SALT.

YOAK, or YOKE, in agriculture, a frame of wood, fitted over the necks of oxen, whereby they are coupled together, and harnessed to the plough.

The Romans made the enemies they subdued, pass under the yoke, which they called, *sub jugam mittere*; that is, they made them pass under a sort of furcæ patibulares, or gallows, consisting of a pike, or other weapon, laid across two others planted upright in the ground. See FURCA.

YOAK of Land, in our ancient customs, was the space which a yoke of oxen (that is, two oxen) may plow in a day.

Sea-YOAK. When the sea is so rough that the helm cannot be governed by the hands, the seamen make a yoke to steer by, that is, they fix two blocks to the end of the helm, and reeving two small ropes through them, which they call falls, by having some men at each tackle, they govern the helm by direction. They have another way of making a sea-

yoak, by taking a double turn about the end of the helm with a single rope, the ends being laid to the ship's sides, by means whereof they guide the helm. See the article HELM.

YOLK, or YELK, *Vitellus*, the yellow part in the middle of an egg. See EGG.

YPSILOIDES, in anatomy, the third genuine future of the cranium, thus called from its resembling a Greek  $\psi$ , or ypsilon.

YUCCA, in botany, a genus of plants, whose flower is campanulated and divided into six large ovate petals, cohering at their base: the stamina are six short filaments, topped with small antheræ: the fruit is an oblong trifid capsule, obtusely triangular, and divided into three cells, which contain many seeds laying over each other in a double order.

The yucca has much the appearance of the aloe, and is propagated in the same manner; and from the dried root of a species, a kind of bread is made by the Indians.

## Z

**Z** The twenty-fourth and last letter, and the nineteenth consonant of our alphabet; the sound of which is formed by a motion of the tongue from the palate downwards and upwards to it again, with a shutting and opening of the teeth at the same time.

This letter has been reputed a double consonant, having the sound *ds*; but some think with very little reason; and, as if we thought otherwise, we often double it, as in *puzzle*, *muzzle*, &c.

Among the ancients, Z was a numeral letter, signifying two thousand; and with a dash added at

top,  $\bar{Z}$ , signified two thousand times two thousand, or four millions.

In abbreviations, this letter formerly stood as a mark for several sorts of weights; sometimes it signified an ounce and a half, and very frequently it stood for half an ounce; sometimes for the eighth part of an ounce, or a dram troy weight; and it was in earlier times used to express the third part of one ounce, or eight scruples. ZZ were used by some of the ancient physicians to express myrrh, and at present they are often used to signify zinziber, or ginger.

**ZACINTHA**, in botany, Vaillant's name for a species of lappana. See the article **LAPSANA**.

**ZAFFER**, or **ZAFFRE**, in chemistry, the name of a blue substance, of the hardness and form of a stone; and generally supposed to be a native fossil.

It is in reality, however, a preparation of cobalt; the calx of that mineral being mixed with powdered flints, and wetted with water to bring it into this form. See the article **COBALT**.

**ZANNICHELLIA**, in botany, a genus of plants, producing male and female flowers; the male flower hath neither cup or corolla, consisting only of a long, erect, single filament, topped with an ovate anthera; the female flower, which is placed near the filament, has no corolla, but consists of a monophyllous ventricose cup, which is scarce visible, and four corniculated germina, which join together, and afterwards become the same number of oblong seeds, which are acuminate on both sides.

**ZANONIA**, in botany, a genus producing male and female flowers on distinct plants; the male flower is monopetalous, and divided into three pointed inflexed segments, with five patent stamina; the corolla of the female flower is like that of the male, and the fruit is a long, very large, truncated berry, attenuated at the base; it contains three cells, in each of which are placed two seeds, of an oblong-roundish figure.

**ZANTHOXYLUM**, in botany, a genus producing male and female flowers on distinct trees; they are both destitute of petals; the cup is divided into five oval, erect, coloured segments; the stamina are five subulated filaments, topped with twin antheræ, which are furrowed: the fruit, which succeeds the female flower, is an oblong unilocular capsule, containing a smooth roundish seed.

**ZEA**, Indian corn, in botany, a genus of plants, producing male and female flowers in spikes; the corolla of the male flower is a bivalvular glume, with two compressed very short nectaria: the stamina are three capillary filaments, topped with quadrangular antheræ; the corolla of the female flower consists of two membranaceous, broad, persistent valves: there is no pericarpium; but the seeds, which are roundish and compressed, are half inclosed in a large long receptacle.

This corn is ground to flour, and the poorest sort of people in America, Italy, and Germany, make their bread with it, and in some countries dress the spikes different ways: but this grain seldom agrees with those who have not been accustomed to eat it. However, it is a better substitute than bean-flour, or other sorts which have, in times of scarcity, been used in England; and will always be found a hearty food for cattle, hogs, and poultry: so that in light sandy lands, where beans and peas succeed not well, this grain may be cultivated to advantage. The season for sowing the seed, is the latter end of March, or beginning of April.

**ZEAL**, ζηλος, the exercise of a warm animated affection, or passion, for any thing. See the article **PASSION**.

**ZEALOTS**, an ancient sect of the Jews, so called from their pretended zeal for God's laws, and the honour of religion. The zealots were a most outrageous and ungovernable people; and on pretence of asserting God's laws, and a strictness and purity of religion, assumed a liberty of questioning notorious offenders without staying for the ordinary formalities of law.

**ZEBLICIUM** *Marmor*, in natural history, a name given by several authors to a soft green marble variegated with black and white; and though the authors who have described it have not observed it, yet it no way differs from the white opites of the ancients.

**ZEBRA**, the wild ass, in zoology, a species of equus, transversely striated. See the articles **HORSE** and **Ass**.

The whole animal is party-coloured, or beautifully striped in a transverse direction, with long and broad streaks, alternately of a deep, glossy, and shining brownish and whitish, with some absolutely black. It is a native of many parts of the East. See plate **XCVII. fig. 1.**

**ZECHARIAH**, a canonical book of the Old Testament, containing the predictions of Zechariah, the son of Barachia, and grandson of Iddo. He is the eleventh of the twelve lesser prophets.

**ZEDOARY**, in the materia medica, a root, the several pieces of which differ so much from one another in shape, that they have been divided into two kinds, as if two different things, under the names of the long and round zedoary, being only the several parts of the same root.

**ZEND**, or **ZENDAVESTA**, a book containing the religion of the magians, or worshippers of fire, who were disciples of the famous Zoroaster.

This book was composed by the famous Zoroaster, during his retirement in a cave, and contained all the pretended revelations of that impostor.

**ZENITH**, in astronomy, the vertical point; or a point in the heavens directly over our heads. See the article **NADIR**.

The zenith is called the pole of the horizon, because it is ninety degrees distant from every point of that circle. See the articles **POLE** and **HORIZON**.

**ZENITH-DISTANCE**, is the complement of the meridian altitude of any heavenly object; or it is the remainder, when the meridian altitude is subtracted from ninety degrees. See the articles **COMPLEMENT** and **ALTITUDE**.

**ZENSUS**, in arithmetic, a name given to a square number, or the second power, by some authors.

**ZEPHANIAH**, a canonical book of the Old Testament, containing the predictions of Zephaniah.

Fig. 2. Zibethicus.

Fig. 1. Zebra.

Fig. 6. Xeranthemum.

Fig. 4. Xiphias.

Fig. 5. Zygæna.

niah the son of Cush, and grandson of Gedaliah; being the ninth of the twelve lesser prophets. He prophesied in the time of king Josiah, a little after the captivity of the ten tribes, and before that of Judah; so that he was cotemporary with Jeremiah.

**ZEPHYR**, *Zephyrus*, the west wind; or that which blows from the cardinal point of the horizon opposite the east. See the articles **WIND**, and **WEST**.

**ZEST**, the woody thick skin, quartering the kernel of a walnut; prescribed by some physicians, when dried and taken with white-wine, as a remedy against the gravel.

**Zeft** is also used for a chip of orange or lemon-peel; such as is usually squeezed into ale, wine, &c. to give it a flavour; or the fine ethereal oil which spurts out of that peel on squeezing it.

**ZETETIC METHOD**, in mathematics, the method made use of to investigate or solve a problem.

**ZEUGMA**, a figure in grammar, whereby an adjective or verb which agrees with a nearer word, is also, by way of supplement, referred to another more remote.

**ZIBETHICUS**, the civet-cat, in zoology; the grey meles, with uniform claws. It was long before the form of this creature, to whom we owe the civet, was known, and long after this before it could be determined to what genus of quadrupeds it belonged: it was first supposed of the cat, and afterwards of the dog-kind; but it is truly one of the badger species. It is a large and fierce animal; (See plate **XCVI**. fig. 2.) its size is that of the common badger, but its body is not so bulky; the head is large, oblong, and considerably thick; the forehead is depressed; the snout is rounded and thick; the nose turns up a little; the mouth is wide, and is furnished in a very formidable manner with teeth; and there are a few rigid but very long whiskers about it; the eyes are small, the ears large, obtuse, and patulous; the neck is long, rigid, and thick; the tail long, and resembling that of the common cat; it is covered with hair, and there runs a ridge of the same hair all along the top of the back. The whole animal is of a light silvery colour, variegated in a beautiful manner, with large spots of black; the legs are very robust, almost entirely black, the feet are armed with very long and sharp claws; under the tail is situated the bag, in which is contained the perfume we call civet; and its situation is the same with that which contains the white sebaceous matter in the badger.

**ZIBETHUM**, *Civet*. See **CIVET**.

**ZIMENT-WATER**, or copper-water, in natural history, the name by which some have called water found in places where there are copper-mines, and lightly impregnated with particles of that metal. See **COPPER**.

The most famous spring of this kind is a mile distant from Newfol, in Hungary, in a great copper-mine, where the water is found at different depths, and is received into different basons, for the purpose of separating the copper from it. In some of these it is much more highly sated with this metal than in others, and will make the supposed change of iron into that metal much sooner. The most common pieces of iron used in the experiments, are horse-shoes, nails, and the like; they are found very little altered in shape after the operation, except that their surfaces are more raised. The water which performs this wonderful operation appears greenish in the basons where it stands; but if a glass of it be taken up, it looks clear as crystal; it has no smell, but has a very strong vitriolic and astringent taste, inasmuch, that the lips and tongue are blistered and scorched on tasting it. The miners use this water as a medicine; and whatever sickness they are seized with, they first attempt its cure with large doses of this water, which usually both vomits and purges them briskly; they also use it in disorders of the eyes. The copper produced from these waters is valued by the people much beyond any other copper, as being more ductile, and running easier in the fire. And from the several experiments made upon the water, the true nature of it may be easily understood. It contains a large quantity of the vitriol of copper, which it probably owes to a solution of that metal, by means of the acid of the common pyrites and water. When this is known, the effects are not difficult to be accounted for; there being no real change of one metal into another, but the true state of the case being that the particles of one metal are dissolved and carried away, and those of another metal deposited in their place; a water thus impregnated is a menstruum capable of dissolving iron, and in the solution of that metal becomes so weakened as to let go the copper it before contained in small parcels.

**ZINC**, or **ZINK**. See the article **ZINK**.

**ZINK**, **ZINC**, or **ZINCK**, in natural history, the name of a very remarkable fossil substance, resembling bismuth in appearance, but of a bluer colour. See the article **BISMUTH**.

It is a very remarkable mineral, and one that has never been well understood as to its origin, till of late; for though the world well knew of a long time both zink and lapis calaminaris, and knew that both of them had the remarkable property of turning copper into brass, which one would think might have given a hint to the discovery of a natural alliance between them; yet have they been ever treated of as two different substances, by the writers on these subjects; and Dr. Lawson was the first who ever publicly declared, and proved, lapis calaminaris to be the ore of zink. See the article **CALAMINARIS Lapis**.

**Zink**

## Z I N

Zink is generally confounded with bismuth, tho' in reality a very different body; but the regulus of these two minerals having a very great external resemblance, the vulgar have not distinguished them; and hence we hear of many ores of zink in the less accurate writers, all which are truly the ores of bismuth.

The lapis calaminaris is the true and general ore of zink, yet that mineral is not confined to this ore alone, but is mixed in great abundance in its disseminated particles among the matter of the ores of other metals, particularly of lead.

Our artificers have long been acquainted with zink, under the name of spelter; but none of them till of late have ever been able to make any guess as to its origin. We have much zink brought to us from the East-Indies, under the name of tutenag; yet no body ever knew from what, or how it was produced there; and all that was heretofore known of it was, that among that strange mixture of ores which the great mines yield at Gosselaet in Saxony, when they were fused for other metals, a large quantity of zink was produced; but Dr. Lawson observing, that the flowers of zink and of lapis calaminaris were the same, and that their effects on copper were the same, never ceased his inquiries till he found out the method of separating zink from it.

The pure zink is a solid metal-like body, of a bluish white, and somewhat less brittle than bismuth, especially when gently heated, and most, of all the metallic minerals, approaches to malleability: it melts in a very small fire, and in a strong one takes fire, burning with a bluish-green flame, and subliming into white flowers, which are with difficulty reducible again into the form of zink: in an open fierce fire, it wholly flies off in vapour.

There is great reason to believe, that all the zink or tutenag brought from the East-Indies, is procured from calamine; and we have now on foot at home, a work established by the discoverer of this ore, which will probably make it very soon unnecessary to bring any zink into England, as we have great plenty of the calamine.

The manner of extracting zink from the lapis calaminaris, is this: the lapis calaminaris must be finely pulverized, and well mixed with an eighth part of charcoal-dust, and put into a close retort to prevent the access of air, which would inflame the zink as it rises. The retort is to be placed on a violent fire, sufficient to melt copper. After some time the zink rises, and appears in the form of metallic drops within the neck of the retort. When the vessel is cool, it must be taken out, by breaking off the neck of the retort.

*Flowers of ZINK.* The flowers of zink are a substance famous in the writings of the chemists, who have led their followers into a thousand errors by the names by which they have called them.

## Z I N

Some have called them talc, and a solution of them in vinegar, oil of talc; to which they have attributed very extraordinary qualities. Some have set the ignorant upon a fruitless attempt of extracting an oil from Venetian talc, to do all the things they have commemorated of this oil. Others have called these flowers the sericum: others the aqua sicca philosophorum; and others the philosophic cotton.

The most simple and easy way of obtaining the flowers of zink pure and white, is this: melt the zink in a tall crucible inclined in the furnace in an angle of 45 degrees, or thereabouts; let the fire be moderate, little stronger than would be necessary for the melting of lead. If the zink is left in this state without being stirred, it forms a grey crust upon its surface, and becomes calcined by degrees under it into a granulose white substance; but to have the flowers, the matter must be stirred from time to time with an iron rod, and this crust broken as often as it arises; there will then, after some time, appear a bright white flame, and about two inches above it there will be found a very thick smoak, and with this there will arise a quantity of very white flowers, which will fix themselves to the sides of the crucible in the form of fine cotton.

The flowers are to be separated at times, and by careful management there may be collected from the zink a greater weight of flowers than its own weight, when put into the fire. In working four pounds of zink in this manner, there will be only about an ounce of a calcined earthy matter left at the bottom of the crucible, and the quantity of flowers will be about two drams and a half in each pound, more than the quantity of zink; besides that, it is easy to conceive from the manner of making them, that a great quantity must have been carried away with the smoak. And this is not to be prevented, since, if the vessel be closed to keep in the fumes, the external air being denied free access, the sublimation immediately ceases, and no more flowers can be obtained, till the vessel is again opened, and the air admitted.

The fumes of zink have a strong smell of garlic, and are very noxious to the lungs. The reducing zink into these flowers, is the destroying it absolutely as to its metallic form; for none of the methods used by chemists to bring back metals to their original state, are able to bring these flowers to zink again.

*ZINNIA*, in botany, a genus of plants, producing compound radiated flowers; the female florets form the rays, and the hermaphrodite ones compose the disc; these are numerous and elevated. The female are roundish, ligulated, and persistent; the cup is oblong and imbricated, and contains the seeds, which are oblong and horned.

*ZINZIBER*, or *ZINGIBER*, ginger, in botany,  
the

the naked stalked oval spiked amomum. See the articles AMOMUM and GINGER.

**ZIZANIA**, in botany, a genus of plants, the male corolla whereof is a glume formed of two valves; the female corolla is a glume formed of a single valve, of a cuculated form, and terminated by an arista or awn; there is no calyx in either the male or female flowers; the seed is single, and placed in the bottom of the corolla, which opens horizontally to let it out.

**ZIZIPHORA**, field-basil, in botany, a genus of plants, whose flower is monopetalous and ringent; the tube is cylindric, the length of the cup; the limb is very small; the upper lip is ovate, reflexed, and intire; and the lower lip is broad, patent, and trifid: the stamina are two spreading filaments, topped with oblong antheræ; there is no pericarpium, but the cup contains four seeds, which are oblong and obtuse, gibbous on one side, and angular on the other.

**ZODIAC**, *Zodiacus*, in astronomy, a fascia or broad circle, whose middle is the ecliptic, and its extremes two circles, parallel thereto, at such a distance from it, as to bound or comprehend the excursions of the sun and planets.

The sun never deviates from the middle of the zodiac, i. e. from the ecliptic, but the planets all do more or less. Their greatest deviations, called latitudes, are the measure of the breadth of the zodiac, which is broader or narrower, as the greatest latitude of the planets is made more or less; accordingly, some make it sixteen, some eighteen, and some twenty degrees broad.

The zodiac, cutting the equator obliquely, makes an angle therewith of  $23\frac{1}{2}^{\circ}$ , or more precisely of  $23^{\circ} 29'$ , which is what we call the obliquity of the zodiac, and is the sun's greatest declination.

The zodiac is divided into twelve portions, called signs, and those divisions or signs are denominated from the constellations which anciently possessed each part; but the zodiac being immoveable, and the stars having a motion from west to east, those constellations no longer correspond to their proper signs, whence arises what we call the precession of the equinoxes.

When a star therefore is said to be in such a sign of the zodiac, it is not to be understood of that sign or constellation of the firmament, but only of that twelfth part of the zodiac, or dodecatemory thereof.

Cassini has also observed a track in the heavens, within whose bounds most of the comets, though not all of them, are observed to keep, which for this reason he calls the zodiac of the comets.

This he makes as broad as the other zodiac, and marks it with signs, and constellations like that, as Antinous, Pegasus, Andromeda, Taurus, Orion, the lesser Dog, Hydra, the Centaur, Scorpion, and Sagittary.

**ZONE**, *ζώνη*, in geography and astronomy, a division of the terraqueous globe, with respect to the different degrees of heat found in the different parts thereof.

A zone is the fifth part of the surface of the earth, contained between two parallels. See the article PARALLEL.

The zones are denominated torrid, frigid, and temperate.

The torrid zone is a fascia, or band surrounding the terraqueous globe, and terminated by the two tropics. Its breadth is  $46^{\circ} 58'$ .

The equator, running through the middle of it, divides it into two equal parts, each containing  $23^{\circ} 29'$ . The ancients imagined the torrid zone uninhabitable. See TROPIC and TORRID.

The temperate zones are two fasciæ, or bands, environing the globe, and contained between the tropics and the polar circles: the breadth of each is  $43^{\circ} 2'$ .

The frigid zones are segments of the surface of the earth, terminated, one by the antarctic, and the other by the arctic circle: the breadth of each is  $46^{\circ} 58'$ . See the articles ARCTIC and ANT-ARCTIC.

**ZOOLOGY**, *ζωολογία*, the science of animals. Artedi observes, that this makes one of the three kingdoms, as they are called, of natural history; the vegetable and the mineral being the two others: in these, however, there is this difference made by writers, that while vegetables and minerals are treated of together, as all of a piece in each, the subjects of zoology are divided; and it is made to compose, as it were, several kingdoms.

Whoever is to write on plants or minerals, calls his work a treatise of botany or mineralogy; and we have no words to express any subdivision of them into kingdoms: but, in zoology, we treat, as different subjects, the different parts of it; and the history of birds is separated, by some, from the rest, under the name of ornithology; that of quadrupeds, under the name of tetrapodology; and we have for the rest, the words entomology, amphibiology, and the like, expressing these things which are properly but the parts of zoology, as so many distinct and separate studies. See the articles BOTANY, MINERALOGY, &c.

**ZOOPHORIC**, or ZOOPHORIC COLUMN, is a statuary column, or a column that bears and supports the figure of an animal. See COLUMN.

**ZOOPHORUS**, or ZOPHORUS, in the ancient architecture, the same with frieze in the modern. See the article FRIEZE.

**ZOOPHYTON**, or ZOOPHITE, in natural history, a kind of intermediate body, partaking both of the nature of a sensitive and a vegetable. See the article SENSITIVE Plant.

**ZOOTOMY**, the art of dissecting animals, or living creatures, being the same with anatomy, or rather

rather comparative anatomy. See the articles DISSECTION and ANATOMY.

**ZOPISSA**, naval pitch, a kind of mixture of pitch and tar, scraped off ships that have been a long time at sea.

This matter, by being gradually penetrated by the salt of the sea, becomes partaker of its qualities, and being applied to the body externally, is found to be resolute and deficcative.

**ZOSTERA**, in botany, a genus of plants, whose flower hath no corolla; the cup consists of a plane linear spadix, and contains a great number of very short filaments, topped with ovato-oblong antheræ; the pericarpium is membranaceous, and contains an ovate seed.

**ZUINGLIANS**, a branch of the ancient Christian Reformers, or protestants, so called from their author Huldric Zuinglius, a divine of Switzerland; who, soon after Luther had declared against the church of Rome, and being then minister of the church at Zurich, fell in with him, and preached openly against indulgences, the mass, the celibacy of the clergy, &c.

What he differed from Luther in, concerned the eucharist: for interpreting *hoc est corpus meum*, by *hoc significat corpus meum*, he maintained, that the bread and wine were only significations of the body and blood of Jesus Christ; whereas Luther held a consubstantiation.

As to the matter of grace, Zuinglius seemed inclined to Pelagianism, in which he differed from Calvin.

**ZYGÆNA**, the ballance-fish, in ichthyology, a species of squalus, with a very broad, tranverse, hammer-like head.

This is one of the most extraordinary fish in the world; in its form, the general size is five or six feet, but it grows to be much larger. The head is the most extraordinary figure of that of any fish; it is not oblong, and running in a line with that of the body, but is placed transversely, and has the appearance of the head of a hammer fastened to its

handle, the eyes are large, and placed at the two extremities; the mouth is transverse, cut on the lower part of the head, and furnished with three or four rows of sharp teeth; the nostrils are small, and not very conspicuous, and the foramina at the eyes are oblong and large; the body is oblong and moderately thick; there are two back fins, and a pinnæ ani; the apertures of the gills are ten oblong slits, five on each side, running from just below the head towards the roots of the pectoral fins; the tail is divided into two parts, and the upper of these is much longer than the under. See plate XCVI. fig. 5.

**ZYGOMA**, in anatomy, a bone of the head, otherwise called os jugale, being no single bone, but an union or assemblage of two processes, or eminences of bones; the one from the os temporis, the other from the os malæ; these processes are hence termed the zygomatic processes, and the suture that joins them together, is denominated the zygomatic suture.

**ZYGOMATICUS**, in anatomy, a muscle of the head, arising from the os zygoma, whence its name, and terminating at the angle of the lips. This muscle, though usually single, is sometimes double throughout; at other times it has a double head; sometimes its tail only is bifid, and it is variously interwoven with the adjoining ones. See the preceding article.

**ZYGOPHYLLUM**, bean-capers, in botany, a genus of plants, the corolla whereof is composed of five petals, broadest at the top, obtuse, emarginated, and larger than the cup; the nectarium consists of ten convergent leaves, and includes the germen: the fruit is an oval pentagonal capsule, formed of five valves, containing five cells, with septa adhering to the valves: the seeds are numerous, roundish, and compressed: the figure of the fruit is subject to variation, and there is a species in which the parts of fructification are a fifth less. This genus comprehends the fabago of Tournefort. See the article FABAGO.
